Chapter 1

Introduction

Welcome to RTI® Routing Service, an out-of-the-box solution for integrating disparate and geographically dispersed systems. It scales RTI Connext® DDS applications across domains, LANs and WANs, including firewall and NAT traversal. It also supports DDS-to-DDS bridging by allowing you to make transformations in the data along the way. This allows unmodified DDS applications to communicate even if they were developed using incompatible interface definitions. This is often the case when integrating new and legacy applications or independently developed systems. Using RTI Routing Service Adapter SDK, you can extend Routing Service to interface with non-DDS systems using off-the-shelf or custom developed adapters.

Traditionally, Connext DDS applications can only communicate with applications in the same domain. With Routing Service, you can send and receive data across domains. You can even transform and filter the data along the way! Not only can you change the actual data values, you can change the data’s type. So the sending and receiving applications don’t even need to use the same data structure. You can also control which data is sent by using allow and deny lists.

Figure 1.1: Routing Service Overview

Simply set up Routing Service to pass data from one domain to another and specify any desired data filtering and transformations. No change are required in the Connext DDS applications.

Key benefits of Routing Service:

- It can significantly reduce the time and effort spent integrating and scaling Connext DDS applications across Wide Area Networks and Systems-of-Systems.

- With Routing Service, you can build modular systems out of existing systems. Data can be contained in private domains within subsystems and you can designate that only certain
“global topics” can be seen across domains. The same mechanism controls the scope of discovery. Both application-level and discovery traffic can be scoped, facilitating scalable designs.

- Routing Service provides secure deployment across multiple sites. You can partition networks and protect them with firewalls and NATS and precisely control the flow of data between the network segments.

- It allows you to manage the evolution of your data model at the subsystem level. You can use Routing Service to transform data on the fly, changing topic names, type definitions, QoS, etc., seamlessly bridging different generations of topic definitions.

- Routing Service provides features for development, integration and testing. Multiple sites can each locally test and integrate their core application, expose selected topics of data, and accept data from remote sites to test integration connectivity, topic compatibility and specific use-cases.

- It connects remotely to live, deployed systems so you can perform live data analytics, fault condition analysis, and data verification.

- RTI Routing Service Adapter SDK allows you to quickly build and deploy bridges to integrate DDS and non-DDS systems. This can be done in a fraction of the time required to develop completely custom solutions. Bridges automatically inherit advanced DDS capabilities, including automatic discovery of applications; data transformation and filtering; data lifecycle management and support across operating systems; programming languages and network transports.

1.1 Paths Mentioned in Documentation

This documentation refers to:

- `<NDDSHOME>` This refers to the installation directory for Connext DDS.

The default installation paths are:

- Mac® OS X® systems: `/Applications/rti_connext_dds-version`
- UNIX®-based systems, non-root user: `/home/your user name/rti_connext_dds-version`
- UNIX-based systems, root user: `/opt/rti_connext_dds-version`
- Windows® systems, user without Administrator privileges: `<your home directory>\rti_connext_dds-version`
- Windows systems, user with Administrator privileges: `C:\Program Files\rti_connext_dds-version`

You may also see `$NDDSHOME` or `%NDDSHOME%`, which refers to an environment variable set to the installation path.

Whenever you see `<NDDSHOME>` used in a path, replace it with your installation path.

Note for Windows Users: When using a command prompt to enter a command that includes the path `C:\Program Files` (or any directory name that has a space), en-
Figure 1.2: Quickly build and deploy bridges between natively incompatible protocols and technologies using *Connext DDS*
close the path in quotation marks. For example: "C:\Program Files\rti_connext.dds-
version\bin\rticlouddiscoveryservice.bat"

Or if you have defined the NDDSHOME environment variable:
"%NDDSHOME%\bin\rticlouddiscoveryservice.bat"

- **<path to examples>** By default, examples are copied into your home directory the first time you run RTI Launcher or any script in <NDDSHOME>/bin. This document refers to the location of the copied examples as <path to examples>.

Wherever you see <path to examples>, replace it with the appropriate path.

Default path to the examples:
- Mac OS X systems: /Users/your user name/rti_workspace/version/examples
- UNIX-based systems: /home/your user name/rti_workspace/version/examples
- Windows systems: your Windows documents folder\rti_workspace\version\examples.
  Where 'your Windows documents folder' depends on your version of Windows. For example, on Windows 10 systems, the folder is C:\Users\your user name\Documents.

## 1.2 Files Mentioned in Documentation

<table>
<thead>
<tr>
<th>File</th>

</tr>
</tbody>
</table>

1.2. Files Mentioned in Documentation
Chapter 2

Usage

This chapter explains how to run Routing Service either from the distributed command-line executable or from a library.

2.1 Command-Line Executable

Routing Service runs as a separate application. The script to run the executable is in <NDDSHOME>/bin.

```
rtiroutingservice [options]
```

In this section we will see:

- How to Start Routing Service (Section 2.1.1).
- How to Stop Routing Service (Section 2.1.2).
- Routing Service Command-line Parameters (Section 2.1.3).

2.1.1 Starting Routing Service

To start Routing Service with a default configuration, enter:

```
$NDDSHOME/bin/rtiroutingservice
```

This command will run Routing Service indefinitely until you stop it. See Section 2.1.2.

Table 2.1 describes the command-line parameters.

2.1.2 Stopping Routing Service

To stop Routing Service, press Ctrl-c. Routing Service will perform a clean shutdown.

2.1.3 Routing Service Command-Line Parameters

The following table describes all the command-line parameters available in Routing Service. To list the available commands, run rtiroutingservice -h.
Table 2.1: Routing Service Command-Line Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-appName &lt;string&gt;</td>
<td>Assigns a name to the execution of the Routing Service. Remote commands and status information will refer to the instances using this name. In addition, the names of DomainParticipants created by the service will be based on this name. Default: empty string (uses configuration name).</td>
</tr>
<tr>
<td>-cfgFile &lt;string&gt;</td>
<td>Semicolon-separated list of configuration file paths. Default: unspecified</td>
</tr>
<tr>
<td>-cfgName &lt;string&gt;</td>
<td>Specifies the name of the Routing Service configuration to be loaded. It must match a &lt;routing_service&gt; tag in the configuration file. Default: rti.routingService.builtin.config.default.</td>
</tr>
<tr>
<td>-convertLegacyXml &lt;string&gt;</td>
<td>Converts the legacy XML specified with -cfgFile and produces the result in the specified output path. If no output path is provided, the converted file will be in the same path than -cfgFile with the suffix converted.</td>
</tr>
<tr>
<td>-domainIdBase &lt;int&gt;</td>
<td>Sets the base domain ID. This value is added to the domain IDs for all the DataReader’s DomainParticipants in the configuration file. For example, if you set -domainIdBase to 50 and use domain IDs 0 and 1 in the configuration file, then the Routing Service will use domains 50 and 51. Default: 0</td>
</tr>
<tr>
<td>-D&lt;name&gt;=&lt;value&gt;</td>
<td>Defines a variable that can be used as an alternate replacement for XML environment variables, specified in the form $(VAR_NAME). Note that definitions in the environment take precedence over these definitions.</td>
</tr>
<tr>
<td>-heapSnapshotDir &lt;dir&gt;</td>
<td>Specifies the output directory where the heap monitoring snapshots are dumped. The filename format is RTI_heap_&lt;appName&gt;<em>&lt;processId&gt;</em>&lt;index&gt;. Used only if heap monitoring is enabled. Default: current working directory</td>
</tr>
<tr>
<td>-heapSnapshotPeriod &lt;sec&gt;</td>
<td>Specifies the period at which heap monitoring snapshots are dumped. For example, Routing Service will generate a heap snapshot every &lt;sec&gt;. Enables heap monitoring if &gt; 0. Default: 0 (disabled)</td>
</tr>
<tr>
<td>-help</td>
<td>Prints this help and exits.</td>
</tr>
<tr>
<td>-identifyExecution</td>
<td>Appends the host name and process ID to the service name provided with the -appName option. This option helps ensure unique names for remote administration and monitoring. For example: MyRoutingService_myhost_20024 Default: false</td>
</tr>
<tr>
<td>-ignoreXsdValidation</td>
<td>Loads the configuration even if the XSD validation fails.</td>
</tr>
</tbody>
</table>

Continued on next page
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-licenseFile</td>
<td>Specifies the path to the license file, required for license-managed distributios.</td>
</tr>
<tr>
<td>-listConfig</td>
<td>Prints the available configurations and exits.</td>
</tr>
<tr>
<td>-maxObjectsPerThread &lt;int&gt;</td>
<td>Maximum number of thread-specific objects that can be created. <strong>Default:</strong> 2048</td>
</tr>
<tr>
<td>-noAutoEnable</td>
<td>Starts Routing Service in a disabled state. Use this option if you plan to enable the service remotely. <strong>Overrides:</strong> This option overrides the <code>&lt;routing_service&gt;</code> tag’s “enabled” attribute in the configuration file. <strong>Default:</strong> false</td>
</tr>
<tr>
<td>-pluginSearchPath &lt;path&gt;</td>
<td>Specifies a directory where plug-in libraries are located. <strong>Default:</strong> current working directory</td>
</tr>
<tr>
<td>-remoteAdministrationDomainId &lt;int&gt;</td>
<td>Enables remote administration and sets the domain ID for remote communication. <strong>Overrides:</strong> This option overrides the <code>&lt;administration&gt;</code> tag’s “enabled” attribute and <code>&lt;administration&gt;/&lt;domain_id&gt;</code> in the configuration file. <strong>Default:</strong> unspecified</td>
</tr>
<tr>
<td>-remoteMonitoringDomainId &lt;int&gt;</td>
<td>Enables remote monitoring and sets the domain ID for status publication. <strong>Overrides:</strong> This option overrides <code>&lt;monitoring&gt;/&lt;enabled&gt;</code> and <code>&lt;monitoring&gt;/&lt;domain_id&gt;</code> in the configuration file. <strong>Default:</strong> unspecified</td>
</tr>
<tr>
<td>-skipDefaultFiles</td>
<td>Skips attempting to load the default configuration files <strong>Default:</strong> false</td>
</tr>
<tr>
<td>-stopAfter &lt;int&gt;</td>
<td>Number of seconds the Routing Service runs before it stops. <strong>Default:</strong> (infinite).</td>
</tr>
<tr>
<td>-verbosity &lt;int&gt;</td>
<td>Controls what type of messages are logged: 0. Silent 1. Exceptions (<em>Connext DDS</em> and <em>Routing Service</em>) 2. Warnings (<em>Routing Service</em>) 3. Warnings (<em>Connext DDS</em>) 4. Local (<em>Routing Service</em>) 5. Remote (<em>Routing Service</em>) 6. Activity (<em>Routing Service</em>) and Local (<em>Connext DDS</em>) Each verbosity level, n, includes all the verbosity levels smaller than n. <strong>Default:</strong> 1 (Exceptions)</td>
</tr>
<tr>
<td>-version</td>
<td>Prints the <em>Routing Service</em> version number and exits.</td>
</tr>
</tbody>
</table>

All the command-line parameters are optional; if specified, they override the values of their corresponding settings in the loaded XML configuration. See Section 3 for the set of XML elements that can be overridden with command-line parameters.

### 2.2 Routing Service Library

*Routing Service* can be deployed as a library linked into your application on selected architectures (see Section 12). This allows you to create, configure, and start *Routing Service* instances from your application.

To build your application, add the dependency with the *Routing Service* library under `<NDDSHOME>/lib/<ARCHITECTURE>`, where `<ARCHITECTURE>` is a valid and installed target architecture.
If you are using the C API, see the example in `<path to examples>/routing_service/routing_service_lib`. Example makefiles and project files for several architectures are provided. Also see the README.txt file in the `routing_service_lib/src` directory.

### 2.2.1 Example

```c
struct RTI_RoutingServiceProperty property =
    RTI_RoutingServiceProperty_INITIALIZER;
struct RTI_RoutingService * service = NULL;

/* initialize property */
property.cfg_file = "my_routing_service_cfg.xml";
property.service_name = "my_routing_service";
...

service = RTI_RoutingService_new(&property);
if(service == NULL) {
    /* log error */
    ...
}

if(!RTI_RoutingService_start(service)) {
    /* log error */
    ...
}

while(keep_running) {
    sleep();
    ...
}
...

RTI_RoutingService_delete(service);
```
Chapter 3

Configuration

3.1 Configuring Routing Service

This document describes how to configure Routing Service. For installation instructions or to walk through some simple examples, please see the appropriate section.

When you start Routing Service, you can specify a configuration file in XML format. In that file, you can set properties that control the behavior of the service. This chapter describes how to write a configuration file.

3.2 Terms to Know

Before learning how to configure Routing Service, you should become familiar with a few key terms and concepts:

- A RoutingService entity refers to an execution of Routing Service.
- A DomainRoute defines a two-way mapping between two data domains (DDS, MQTT, AMQP, etc.).
- A Session defines a safe, threaded context for Routes. A Route can be processed by a single thread at a time. If the session defines a thread pool, Routes can be processed concurrently.
- A Route defines a mapping between input streams and output streams belonging to any of the data domains defined in a DomainRoute. For example, in a Route between DDS and MQTT, the input streams will be DDS topics and the output streams will be MQTT subscriptions.
- An AutoRoute defines a set of potential Routes that can be instantiated based on deny/allow filters on the stream name and registered type name.
- A Transformation is a pluggable component that changes data from an input stream to an output stream.
- An Adapter is a pluggable component that allows Routing Service to consume and produce data for different data domains. By default, Routing Service is distributed with a builtin DDS adapter.
3.3 How to Load the XML Configuration

Routing Service loads its XML configuration from multiple locations. This section presents the various sources of configuration files, listed in load order.

- [working directory]/USER_ROUTING_SERVICE.xml This file is loaded automatically if it exists.
- [NDDSHOME]/resource/xml/RTI_ROUTING_SERVICE.xml This file is loaded automatically if it exists.
- File specified using the command-line parameter `-cfgFile`.

Note: [working directory] indicates the path to the current working directory from which you run Routing Service.

The tag [NDDSHOME] indicates the path to your Connext DDS installation.

You may use a combination of the above sources and load multiple configuration files.

Here is an example configuration file. You will learn the meaning of each line as you read the rest of this section.

```xml
<?xml version="1.0"?>
<dds>
  <routing_service name="TopicBridgeExample" group_name="MyGroup">
    <domain_route name="DomainRoute">
      <participant name="domain0"><domain_id>0</domain_id></participant>
      <participant name="domain1">
        <domain_id>1</domain_id></participant>
    </domain_route>
    <session name="Session">
      <topic_route name="SquaresToCircles">
        <input participant="domain0">
          <registered_type_name>ShapeType</registered_type_name>
          <topic_name>Square</topic_name>
        </input>
        <output participant="domain1">
          <registered_type_name>ShapeType</registered_type_name>
          <topic_name>Circle</topic_name>
        </output>
      </topic_route>
    </session>
  </routing_service>
</dds>
```

(continues on next page)
3.4 XML Syntax and Validation

The XML representation of DDS-related resources must follow these syntax rules:

- It shall be a well-formed XML document according to the criteria defined in clause 2.1 of the Extensible Markup Language standard.
- It shall use UTF-8 character encoding for XML elements and values.
- It shall use <dds> as the root tag of every document.

To validate the loaded configuration, Routing Service relies on an XSD file that describes the format of the XML content. We recommend including a reference to this document in the XML file that contains the service’s configuration; this provides helpful features in code editors such as Visual Studio®, Eclipse®, and NetBeans®, including validation and auto-completion while you are editing the XML file.

The XSD definitions of the XML elements are in [NDDSHOME]/resources/schema/rti_routing_service.xsd.

To include a reference to the XSD document in your XML file, use the attribute xsi:noNamespaceSchemaLocation in the <dds> tag. For example:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<dds xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
     xsi:noNamespaceSchemaLocation="[NDDSHOME]/resource/schema/rti_routing_service.xsd">
    <!-- ... -->
</dds>
```

Note: The tag [NDDSHOME] indicates the path to your Connext DDS installation.

3.5 XML Tags for Configuring RTI Routing Service

This section describes the XML tags you can use in a Routing Service configuration file. The following diagram and Table 3.1 describe the top-level tags allowed within the root <dds> tag.
Figure 3.1: Top-level Tags in the Configuration File

Table 3.1: Top-Level Tags in the Configuration File

<table>
<thead>
<tr>
<th>Tags within <code>&lt;dds&gt;</code></th>
<th>Description</th>
<th>Multiplicity</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;qos_library&gt;</code></td>
<td>Specifies a QoS library and profiles. The contents of this tag are specified in the same manner as for a <em>Connext DDS</em> application. See Configuring QoS with XML, in the <em>Connext DDS Core Libraries User’s Manual</em>.</td>
<td>0..*</td>
</tr>
<tr>
<td><code>&lt;types&gt;</code></td>
<td>Defines types that can be used by <em>Routing Service</em>. See Section 3.5.6.</td>
<td>0..1</td>
</tr>
<tr>
<td><code>&lt;plugin_library&gt;</code></td>
<td>Specifies a library of <em>Routing Service</em> plugins. Available plug-ins are <em>Adapters</em>, <em>Transformations</em> and <em>Processors</em>. See Section 3.5.9.</td>
<td>0..*</td>
</tr>
</tbody>
</table>

<tr>
<td></td>
<td>• name: Uniquely identifies a Routing Service configuration. Optional.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• enabled: A boolean that indicates whether this entity is auto-enabled when the service starts. If set to false, the entity can be enabled after the service starts through remote administration. Optional. Default: true.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• group_name: A name that can be used to implement a specific policy when the communication happens between Routing Service of the same group. For example, in the builtin DDS adapter, a DomainParticipant will ignore other DomainParticipants in the same group, as a way to avoid circular communication. Optional. Default: RTI_RoutingService_[HostName]_[Process ID]</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Example</td>
<td></td>
</tr>
<tr>
<td></td>
<td>&lt;routing_service name=&quot;ExampleService&quot;&gt;</td>
<td></td>
</tr>
<tr>
<td></td>
<td>&lt;!-- your service settings ... --&gt;</td>
<td></td>
</tr>
<tr>
<td></td>
<td>&lt;/routing_service&gt;</td>
<td></td>
</tr>
</tbody>
</table>

3.5.1 Routing Service Tag

A configuration file must have at least one <routing_service> tag. This tag is used to configure an execution of Routing Service. A configuration file may contain multiple <routing_service> tags.

When you start Routing Service, you can specify which <routing_service> tag to use to configure the service using the -cfgName command-line parameter.

Because a configuration file may contain multiple <routing_service> tags, one file can be used to configure multiple Routing Service executions.

Figure 3.2 and Table 3.2 describes the tags allowed within a <routing_service> tag.

Table 3.2: Routing Service Tag

<table>
<thead>
<tr>
<th>Tags within &lt;routing_service&gt;</th>
<th>Description</th>
<th>Multiplicity</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;annotation&gt;</td>
<td>Contains a &lt;documentation&gt; tag that can be used to provide a configuration description.</td>
<td>0..1</td>
</tr>
<tr>
<td>Tags within <code>&lt;routing_service&gt;</code></td>
<td>Description</td>
<td>Multiplicity</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td><code>&lt;administration&gt;</code></td>
<td>Enables and configures remote administration. See Section 3.5.2 and Section 4.</td>
<td>0..1</td>
</tr>
<tr>
<td><code>&lt;monitoring&gt;</code></td>
<td>Enables and configures general remote monitoring. General monitoring settings are applicable to all the <em>Routing Service</em> entities unless they are explicitly overridden. See Section 3.5.3 and Section 5.</td>
<td>0..1</td>
</tr>
<tr>
<td><code>&lt;entity_monitoring&gt;</code></td>
<td>Enables and configures remote monitoring for the service entity. See Section 3.5.3 and Section 5.</td>
<td>0..1</td>
</tr>
</tbody>
</table>
| `<jvm>`                         | Configures the Java JVM used to load and run Java adapters. For example:  
   **Example**  
   ```xml
   <jvm>
     <class_path>
       <element>SocketAdapter.jar</element>
     </class_path>
     <options>
       <element>-Xms32m</element>
       <element>-Xmx128m</element>
     </options>
   </jvm>
   ```  
   You can use the `<options>` tag to specify options for the JVM, such as the initial and maximum Java heap sizes. | 0..1          |
| `<domain_route>`                | Defines a mapping between two or more data domains. See Section 3.5.4.  
   Attributes  
   - `name`: uniquely identifies a *DataReader* configuration. Optional.  
   - `enabled`: A boolean that indicates whether this entity is auto-enabled when the service starts. If set to false, the entity can be enabled after the service starts through remote administration. Optional. Default: true. | 0..1          |

**Example: Specifying a configuration in XML**

```xml
<dds>
  <routing_service name="EmptyConfiguration"/>
  <routing_service name="ShapesDemoConfiguration">
    <!--...-->
  </routing_service>
</dds>
```

Starting *Routing Service* with the following command will use the `<routing_service>` tag with the name `EmptyConfiguration`.  

---

### 3.5. XML Tags for Configuring RTI Routing Service

14
3.5.2 Administration

You can create a Connext DDS application that can remotely control Routing Service. The `<administration>` tag is used to enable remote administration and configure its behavior. By default, remote administration is turned off in Routing Service for security reasons. A remote administration section is not required in the configuration file.

When remote administration is enabled, Routing Service will create a DomainParticipant, Publisher, Subscriber, DataWriter, and DataReader. These entities are used to receive commands and send responses. You can configure these entities with QoS tags within the `<administration>` tag. The following table lists the tags allowed within `<administration>` tag. Notice that the `<domain_id>` tag is required.

For more details, please see Section 4.

Note: The command-line options used to configure remote administration take precedence over the XML configuration (see Section 2).

---

### Table 3.3: Administration Tag

<table>

3.5.3 Monitoring

You can create a Connext DDS application that can remotely monitor the status of Routing Service. To enable remote monitoring and configure its behavior, use the `<monitoring>` and `<entity_monitoring>` tags.

By default, remote monitoring is turned off in Routing Service for security and performance reasons. A remote monitoring section is not required in the configuration file.

When remote monitoring is enabled, Routing Service will create one DomainParticipant, one Publisher, five DataWriters for data publication (one for each kind of entity), and five DataWriters for status publication (one for each kind of entity). You can configure the QoS of these entities with the `<monitoring>` tag defined under `<routing_service>`. The general remote monitoring parameters specified using the `<monitoring>` tag in `<routing_service>` can be overwritten on a per entity basis using the `<entity_monitoring>` tag.

For more details, please see Section 5.

**Note:** The command-line options used to configure remote monitoring take precedence over the XML configuration (See Section 2).

Table 3.4: Monitoring Tag

<table>
<thead>

<table>
<thead>
<tr>
<th>Tags within <code>&lt;monitoring&gt;</code></th>
<th>Description</th>
<th>Multiplicity</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;participant_qos&gt;</code></td>
<td>Configures the <code>DomainParticipant</code> QoS for remote monitoring. If the tag is not defined, <code>Routing Service</code> will use the <code>Connext DDS</code> defaults, with the following change: • <code>resource_limits.type_code_max_serialized_length = 4096</code></td>
<td>0..1</td>
</tr>
<tr>
<td><code>&lt;publisher_qos&gt;</code></td>
<td>Configures the <code>Publisher</code> QoS for remote monitoring. If the tag is not defined, <code>Routing Service</code> will use the <code>Connext DDS</code> defaults.</td>
<td>0..1</td>
</tr>
<tr>
<td><code>&lt;datawriter_qos&gt;</code></td>
<td>Configures the <code>DataWriter</code> QoS for remote monitoring. If the tag is not defined, <code>Routing Service</code> will use the <code>Connext DDS</code> defaults with the following change: • <code>durability.kind = DDS_TRANSIENT_LOCAL_DURABILITY_QOS</code></td>
<td>0..1</td>
</tr>
<tr>
<td><code>&lt;statistics_sampling_period&gt;</code></td>
<td>Specifies the frequency, in seconds, at which status statistics are gathered. Statistical variables such as latency are part of the entity status. <strong>Example:</strong> <code>&lt;statistics_sampling_period&gt;</code> <code>&lt;sec&gt;1&lt;/sec&gt;</code> <code>&lt;nanosec&gt;0&lt;/nanosec&gt;</code> <code>&lt;/statistics_sampling_period&gt;</code> The statistics period for a given entity should be smaller than the publication period. The statistics sampling period defined in <code>&lt;routing_service&gt;</code> is inherited by all the entities. An entity can overwrite the period. <strong>Default:</strong> 1</td>
<td>0..1</td>
</tr>
<tr>
<td><code>&lt;statistics_publication_period&gt;</code></td>
<td>Specifies the frequency, in seconds, at which the status of an entity is published. <strong>Example:</strong> <code>&lt;statistics_publication_period&gt;</code> <code>&lt;sec&gt;5&lt;/sec&gt;</code> <code>&lt;nanosec&gt;0&lt;/nanosec&gt;</code> <code>&lt;/statistics_publication_period&gt;</code> The statistics sampling period defined in <code>&lt;routing_service&gt;</code> is inherited by all the entities. An entity can overwrite the period. <strong>Default:</strong> 5</td>
<td>0..1</td>
</tr>
</tbody>
</table>

**Monitoring Configuration Inheritance**

The monitoring configuration defined in `<routing_service>` is inherited by all the entities defined inside the tag.

An entity can overwrite three elements of the monitoring configuration:
- The status publication period
- The statistics sampling period
- The historical statistics windows

Each one of these three elements is inherited and can be overwritten independently using the `<entity_monitoring>` tag.

### Table 3.5: Entity Monitoring Tag

<table>
<thead>
<tr>
<th>Tags within <code>&lt;entity_monitoring&gt;</code></th>
<th>Description</th>
<th>Multiplicity</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;enabled&gt;</code></td>
<td>Enables/disables remote monitoring for a given entity. If general monitoring is disabled, this value is ignored. <strong>Default:</strong> true</td>
<td>0..1</td>
</tr>
</tbody>
</table>
| `<statistics_sampling_period>`    | Specifies the frequency at which status statistics are gathered. Statistical variables such as latency are part of the entity status. **Example:**

```xml
<statistics_sampling_period>
  <sec>1</sec>
  <nanosec>0</nanosec>
</statistics_sampling_period>
```

The statistics period for a given entity should be smaller than the publication period.
If this tag is not defined, historical statistics are inherited from the general monitoring settings. **Default:** 1 second. | 0..1 |
| `<statistics_publication_period>` | Specifies the frequency at which the status of an entity is published. **Example:**

```xml
<statistics_publication_period>
  <sec>5</sec>
  <nanosec>0</nanosec>
</statistics_publication_period>
```

If this tag is not defined, historical statistics are inherited from the general monitoring settings. **Default:** 5 seconds. | 0..1 |

### Example: Overriding Publication Period

```xml
<routing_service name="MonitoringExample">
  <monitoring>
    <domain_id>55</domain_id>
    <status_publication_period>
      <sec>1</sec>
    </status_publication_period>
    <statistics_sampling_period>
      (continues on next page)
    </statistics_sampling_publication_period>
  </monitoring>
</routing_service>
```
3.5.4 Domain Route

A `<domain_route>` defines a mapping between different data domains. Data available in any of these data domains can be routed to other data domains. For example, a DomainRoute could define a mapping among multiple DDS domains, or between a DDS domain and a MQTT provider’s network. How this data is actually read and written is defined in specific Routes.

A `<domain_route>` creates one or more Connections. Each Connection typically belongs to a different data domain. The `<connection>` tag requires the specification of the attribute name, which will be used by the Route to select input and output domains, and the plugin_name, which will be used to associate a Connection with an adapter plugin defined within `<adapter_library>`.

Routing Service comes with a builtin implementation of a DDS adapter, which can be used by specifying the `<participant>` tag. Each tag corresponds to exactly one DomainParticipant. A DomainRoute can include both `<connection>` and `<participant>` tags to provide communication between DDS domains and other data domains.

<th>Description</th>
<th>Multiplicity</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;registered_type&gt;</code></td>
<td>Registers a type name and associates it with a type representation. When you define a type in the configuration file, you have to register the type in order to use it in Routes. See Section 3.5.6.</td>
<td>0..*</td>
</tr>
</tbody>
</table>

### Table 3.8: Participant Tag

<table>
<thead>
<tr>
<th>Tags within <code>&lt;participant&gt;</code></th>
<th>Description</th>
<th>Multiplicity</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;domain_id&gt;</code></td>
<td>Sets the domain ID associated with the DomainParticipant. <strong>Default:</strong> 0</td>
<td>0..1</td>
</tr>
<tr>
<td><code>&lt;participant_qos&gt;</code></td>
<td>Sets the participant QoS. The contents of this tag are specified in the same manner as a Connext DDS QoS profile. If not specified, the DDS defaults are used, except for the participant name which takes the following value: “RTI Routing Service: <code>&lt;service name&gt;</code>. <code>&lt;domain route name&gt;</code># `[1</td>
<td>2]” (for example “RTI Routing Service: MyService.MyDomainRoute#1”). <strong>Note:</strong> Changing the default participant name may prevent Routing Service from being detected by Admin Console. You can use a <code>&lt;participant_qos&gt;</code> tag inside a <code>&lt;qos_library&gt;</code>/&lt;qos_profile&gt; previously defined in your configuration file by referring to it, and also override any value: <strong>Example:</strong></td>
</tr>
</tbody>
</table>

```xml
<participant_qos base_name="MyLibrary::MyProfile">
  <discovery>
    <initial_peers>
      <element>udp4://192.168.1..12</element>
      <element>shmem://</element>
    </initial_peers>
  </discovery>
</participant_qos>
```

Table 3.8 – continued from previous page

<table>
<thead>
<tr>
<th>Tags within &lt;participant&gt;</th>
<th>Description</th>
<th>Multiplicity</th>
</tr>
</thead>
</table>
| <memory_management>      | Configures certain aspects of how Connext DDS allocates internal memory. The configuration is per DomainParticipant and therefore affects all the contained DDS entities.  
**Example:**  

```xml
<memory_management>
  <sample_buffer_min_size>
    1024
  </sample_buffer_min_size>
  <sample_buffer_trim_to_size>
    true
  </sample_buffer_trim_to_size>
</memory_management>
```

This tag includes the following tags:
- **sample_buffer_min_size**: For all DataReaders and DataWriters, the way Connext DDS allocates memory for samples is as follows: Connext DDS pre-allocates space for samples up to size X in the DataReader and DataWriter queues. If a sample has an actual size greater than X, the memory is allocated dynamically for that sample. The default size is 64KB. This is the maximum amount of pre-allocated memory. Dynamic memory allocation may occur when necessary if samples require a bigger size.
- **sample_buffer_trim_to_size**: If set to true, after allocating dynamic memory for very large samples, that memory will be released when possible. If false, that memory will not be released but kept for future samples if needed. The default is false.

This feature is useful when a data type has a very high maximum size (e.g., megabytes) but most of the samples sent are much smaller than the maximum possible size (e.g., kilobytes). In this case, the memory footprint is reduced dramatically, while still correctly handling the rare cases in which very large samples are published.

| <registered_type> | Registers a type name and associates it with a type representation. When you define a type in the configuration file, you have to register the type in order to use it in Routes. See Section 3.5.6. | 0..* |
Example: Mapping between Two DDS Domains

```xml
<domain_route name="DdsDomainRoute">
    <participant name="domain54">
        <domain_id>54</domain_id>
        ...
    </participant>

    <participant name="domain55">
        <domain_id>55</domain_id>
        ...
    </participant>

    ...
</domain_route>
```

Example: Mapping between a DDS Domain and raw Sockets

```xml
<domain_route name="DomainRoute">
    <connection name="SocketAdapter">
        ...
    </connection>

    <participant name="domain55">
        <domain_id>55</domain_id>
        ...
    </participant>

    ...
</domain_route>
```

3.5.5 Session

A `<session>` tag defines a multi-threaded context for route processing, including data forwarding. The data is routed according to specified Routes and AutoRoutes.

Each Session will have an associated thread pool to process Routes concurrently, preserving Route safety. Multiple Routes can be processed concurrently, but a single Route can be processed only by one thread at time. By default, the session thread pool has a single thread, which serializes the processing of all the Routes.

Sessions that bridge domains will create a Publisher and a Subscriber from the DomainParticipants associated with the domains. Table 3.9 lists the tags allowed within a `<session>` tag.

<table>
<thead>
<tr>
<th>Tags within <code>&lt;session&gt;</code></th>
<th>Description</th>
<th>Multiplicity</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;entity_monitoring&gt;</code></td>
<td>Enables and configures remote monitoring for the Session. See Section 5.</td>
<td>0..1</td>
</tr>
</tbody>
</table>

Table 3.9: Session Tag

Continued on next page
<table>
<thead>
<tr>
<th>Tags within <code>&lt;session&gt;</code></th>
<th>Description</th>
<th>Multiplicity</th>
</tr>
</thead>
</table>
| `<thread_pool>`        | Defines the number of threads to process *Routes* and sets the mask, priority, and stack size of each thread. **Example:**  
  `<thread_pool>`  
  `  `<mask>`MASK_DEFAULT`</mask>`  
  `  `<priority>`THREAD_PRIORITY_DEFAULT`</priority>`  
  `</thread_pool>`  
  **Default values:**  
  - *size*: 1  
  - *mask*: MASK_DEFAULT  
  - *priority*: THREAD_PRIORITY_DEFAULT  
  - *stack_size*: THREAD_STACK_SIZE_DEFAULT | 0..1 |
| `<periodic_action>`    | Enables the periodic event dispatching to Processors. If enabled, the *Session* will wake up and notify the installed Processor specified period. **Default**: INFINITE (no periodic notification) | 0..1 |
| `<property>`           | A sequence of name-value string pairs that allows you to configure the *Session* instance. **Example:**  
  `<property>`  
  `  `<value>`  
  `    `<element>`  
  `      `<name>`com.rti.socket.timeout`</name>`  
  `    `</element>`  
  `  `</value>`  
  `</property>`  
  These properties are only used in non-DDS domains. | 0..1 |
### Tags within `<session>`

<table>
<thead>
<tr>
<th>Tag</th>
<th>Description</th>
<th>Multiplicity</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;subscriber_qos&gt;</code></td>
<td>Only applicable to Routes that are Connext DDS Routes. Sets the QoS associated with the session Subscribers. There is one Subscriber per DomainParticipant. The contents of this tag are specified in the same manner as a Connext DDS QoS profile. See Configuring QoS with XML, in the Connext DDS Core Libraries User’s Manual. If the tag is not defined, Routing Service will use the Connext DDS defaults.</td>
<td>0..1</td>
</tr>
<tr>
<td><code>&lt;publisher_qos&gt;</code></td>
<td>Only applicable to Routes that are Connext DDS Routes. Sets the QoS associated with the session Publisher. There is one Publisher per DomainParticipant. The contents of this tag are specified in the same manner as a Connext DDS QoS profile. See Configuring QoS with XML, in the Connext DDS Core Libraries User’s Manual. If the tag is not defined, Routing Service will use the Connext DDS defaults.</td>
<td>0..*</td>
</tr>
</tbody>
</table>
| `<topic_route>` or `<route>` | Defines a mapping between multiple input and output streams. Attributes
- `name`: uniquely identifies a TopicRoute or Route configuration. Optional.
- `enabled`: A boolean that indicates whether this entity is auto-enabled when the service starts. If set to false, the entity can be enabled after the service starts through remote administration. Optional. Default: true. See Section 3.5.6. | 0..* |
| `<auto_topic_route>` or `<auto_route>` | Defines a factory for Route based on type and stream filters. See Section 3.5.8. Attributes
- `name`: uniquely identifies an AutoTopicRoute or AutoRoute configuration. Optional.
- `enabled`: A boolean that indicates whether this entity is auto-enabled when the service starts. If set to false, the entity can be enabled after the service starts through remote administration. Optional. Default: true. | 0..* |

### 3.5.6 Route

A Route explicitly defines a mapping between one or more input data streams and one or more output data streams. The input and output streams may belong to different data domains.

---

3.5. XML Tags for Configuring RTI Routing Service 26
Route events are processed in the context of the thread belonging to the parent Session. Route event processing includes, among others, calls to the StreamReader read and StreamWriter write operations.

Table 3.10 lists the tags allowed within a <route>. Table 3.11 lists the tags allowed within a <topic_route>.

### Table 3.10: Route Tag

### Route Types

The tag `<registered_type_name>` within the `<input>` and `<output>` tags contains the registered type name of the stream. The actual definition of that type can be set in the configuration file or it can be discovered by the connections.

#### Defining Types in the Configuration File

To define and use a type in your XML configuration file:

- Define your type within the `<types>` tag. The type description is done using the *Connext DDS* XML format for type definitions. See Creating User Data Types with Extensible Markup Language (XML), in the *RTI Connext DDS Core Libraries User’s Manual*.
- Register it in the `<connection>`/<`participant`> where you will use it.
- Refer to it in the domain route(s) that will use it.

#### Example: Type Registration in XML

```xml
<dds>
  ...
  <types>
    <struct name="PointType">
      ...
    </struct>
  </types>
  ...
  <routing_service name="MyRoutingService">
    ...
    <domain_route>
      <connection name="MyConnection">
        ...
        <registered_type name="Position" type_name="PointType"/>
      </connection>
      <participant name="MyParticipant">
        ...
        <registered_type name="Position" type_name="PointType"/>
      </participant>
      ...
      <session>
        <topic_route>
        ...
      </session>
  </routing_service>
</dds>
```

(continues on next page)
<input participant="2">
  <registered_type_name>Position</registered_type_name>
</input>
...
</topic_route>
</session>
...
</domain_route>
...
</routing_service>
...
</dds>

Discovering Types

If a Route refers to types that are not defined in the configuration file, Routing Service has to discover their type representation (e.g. typecode). A Route cannot be created without the type representation information.

By default, the StreamReader creation will be tied to the discovery of types in the input domain and the StreamWriter creation will be tied to the discovery of types in the output domain. If you want to use types discovered in either one of the domains for the creation of both the StreamReader and StreamWriter, you must set the <route_types> tag to true.

Example: Route Creation with Type Obtained from Discovery

<dds>
  ...
  <routing_service name="MyRoutingService">
    ...
    <domain_route>
      <participant name="MyParticipant"/>
      ...
      <session>
        <topic_route>
          <input participant="domain1">
            <registered_type_name>Position</registered_type_name>
          </input>
          ...
        </topic_route>
      </session>
      ...
    </domain_route>
    ...
  </routing_service>
  ...
</dds>
3.5.7 Input/Output

Inputs and outputs in a Route or TopicRoute have an associated StreamReader and StreamWriter, respectively. For DDS domains, the StreamReader will contain a DataReader and the StreamWriter will contain a DataWriter. The DataReaders and DataWriters belong to the corresponding Session Subscriber and Publisher.

DDS inputs and outputs within a Route are defined using the <dds_input> and <dds_output> tags. Inputs and outputs from other data domains are defined using the <input> and <output> tags. A TopicRoute is a special kind of Route that allows defining mapping between DDS topics only.

Table 3.12: Route Input/Output Tags

<table>
<thead>
<tr>
<th>Tags within &lt;input&gt; and &lt;output&gt; of &lt;route&gt;</th>
<th>Description</th>
<th>Multiplicity</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;entity_monitoring&gt;</td>
<td>Enables and configures remote monitoring for the Input/Output. See Section 5.</td>
<td>0..1</td>
</tr>
<tr>
<td>&lt;stream_name&gt;</td>
<td>Specifies the stream name.</td>
<td>1</td>
</tr>
<tr>
<td>&lt;registered_type_name&gt;</td>
<td>Specifies the registered type name of the stream.</td>
<td>1</td>
</tr>
<tr>
<td>&lt;creation_mode&gt;</td>
<td>Specifies when to create the StreamReader/StreamWriter. <strong>Default:</strong> IMMEDIATE See Section 3.5.7.</td>
<td>0..1</td>
</tr>
</tbody>
</table>
| <property>                               | A sequence of name-value string pairs that allows you to configure the StreamReader/StreamWriter. **Example:**  
  
  ```xml
  <property>
    <value>
      <element>
        <name>com.rti.socket.port</name>
        <value>16556</value>
      </element>
    </value>
  </property>
  ```
|                                           | 0..1 |
| <transformation> (within <output> only)   | Sets a data transformation to be applied for every data sample. See Section 3.5.7. Attributes  
  - **plugin_name:** Name of the plug-in that creates a Transformation object. This name shall refer to a transformation plug-in registered either in a <plugin_library> or with the service attach_transformation() operation. | 0..1 |
### Table 3.13: TopicRoute Input/Output Tags

<table>
<thead>
<tr>
<th>Tags within <code>&lt;input&gt;</code> and <code>&lt;output&gt;</code> (in <code>&lt;topic_route&gt;</code>) and <code>&lt;dds_input&gt;</code> and <code>&lt;dds_output&gt;</code> (in <code>&lt;route&gt;</code>)</th>
<th>Description</th>
<th>Multiplicity</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;topic_name&gt;</code></td>
<td>Specifies the topic name.</td>
<td>1</td>
</tr>
<tr>
<td><code>&lt;registered_type_name&gt;</code></td>
<td>Specifies the registered type name of the topic.</td>
<td>1</td>
</tr>
<tr>
<td><code>&lt;creation_mode&gt;</code></td>
<td>Specifies when to create the Stream-Reader/StreamReader. <strong>Default:</strong> IMMEDIATE See Section 3.5.7.</td>
<td>0..1</td>
</tr>
<tr>
<td><code>&lt;datareader_qos&gt;</code> or <code>&lt;datawriter_qos&gt;</code></td>
<td>Sets the DataReader or DataWriter QoS. The contents of this tag are specified in the same manner as a Connext DDS QoS profile. See Configuring QoS with XML, in the Connext DDS Core Libraries User’s Manual. If the tag is not defined, Routing Service will use the Connext DDS defaults.</td>
<td>0..1</td>
</tr>
</tbody>
</table>
| `<content_filter>` | Defines a SQL content filter for the DataReader. Example:  

```xml
<content_filter>
  <expression>
    x &gt; 100
  </expression>
</content_filter>
```
| 0..1 |
| `<transformation>` (within `<output>` only) | Sets a data transformation to be applied for every data sample. See Section 3.5.7. Attributes  

- `plugin_name`: Name of the plug-in that creates a Transformation object. This name shall refer to a transformation plug-in registered either in a `<plugin_library>` or with the service attach_transformation() operation. | 0..1 |

### Creation Modes

The way a Route creates its StreamReaders and StreamWriters and starts reading and writing data can be configured.

The `<creation_mode>` tag in a Route’s `<input>` and `<output>` tags controls when StreamReaders/StreamWriters are created.
### Table 3.14: Route Creation Mode

<table>
<thead>
<tr>
<th>&lt;creation_mode&gt; values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMMEDIATE</td>
<td>The StreamReader/StreamWriter is created as soon as possible; that is, as soon as the types are available. Note that if the type is defined in the configuration file, the creation will occur when the service starts.</td>
</tr>
<tr>
<td>ON_DOMAIN_MATCH</td>
<td>The StreamReader is not created until the associated connection discovers a data Producer on the same stream. If the adapter supports partition, the discovered Producer must also belong to the same partition for a match to occur. For example, a DDS input will not create a DataReader until a DataWriter for the same topic and partition is discovered on the same domain. The StreamWriter is not created until the associated connection discovers a data Consumer on the same stream. If the adapter supports partition, the discovered Producer must also belong to the same partition for a match to occur. For example, a DDS output will not create a DataWriter until a DataReader for the same topic and partition is discovered on the same domain.</td>
</tr>
<tr>
<td>ON_ROUTE_MATCH</td>
<td>The StreamReader/StreamWriter is not created until all its counterparts in the Route are created.</td>
</tr>
<tr>
<td>ON_DOMAIN_AND_ROUTE_MATCH</td>
<td>Both conditions must be true.</td>
</tr>
<tr>
<td>ON_DOMAIN_OR_ROUTE_MATCH</td>
<td>At least one of the conditions must be true.</td>
</tr>
</tbody>
</table>

The same rules also apply to the StreamReader/StreamWriter destruction. When the condition that triggered the creation of that entity becomes false, the entity is destroyed. Note that IMMEDIATE will never become false.

For example, if the creation mode of an <input> tag is ON_DOMAIN_MATCH, when all the matching user DataWriters in the input domain are deleted, the input DataReader is deleted.

**Example: Route Starts as Soon as a User DataWriter is Publishing on 1st Domain**

```xml
<topic_route>
  <input participant="domain1">
    <creation_mode>ON_DOMAIN_MATCH</creation_mode>
    ...
  </input>
  <output participant="domain2">
    <creation_mode>ON_ROUTE_MATCH</creation_mode>
    ...
  </output>
</topic_route>
```
Example: Route Starts when Both User DataWriter Appears in 1st Domain and User DataReader Appears in 2nd Domain

```xml
<topic_route>
  <input participant="domain1">
    <creation_mode>ON_DOMAIN_AND_ROUTE_MATCH</creation_mode>
    ...
  </input>
  <output participant="domain2">
    <creation_mode>ON_DOMAIN_AND_ROUTE_MATCH</creation_mode>
    ...
  </output>
</topic_route>
```

Data Transformation

An Output can transform the incoming data using a Transformation. To instantiate a Transformation:

1. Implement the transformation plugin API and register in a plug-in library, or attach it to a service instance if you are using the Service API. See Section 6.

2. Instantiate a Transformation object by specifying a <transformation> tag inside a <output> or <dds_output>.

Table 3.15 lists the tags allowed within a <transformation> tag.

<table>
<thead>
<tr>
<th>Tags within &lt;transformation&gt;</th>
<th>Description</th>
<th>Multiplicity</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;property&gt;</td>
<td>A sequence of name-value string pairs that allows you to configure the custom Transformation plug-in object. Example:</td>
<td>0..1</td>
</tr>
</tbody>
</table>

```xml
<property>
  <value>
    <element>
      <name>X</name>
      <value>Y</value>
    </element>
    <element>
      <name>Y</name>
      <value>X</value>
    </element>
  </value>
</property>
```

3.5.8 Auto Route

The tag <auto_route> defines a set of potential Routes, with single input and output, both with the same registered type and stream name. A Route can eventually be instantiated when a new
stream is discovered with a type name and a stream name that match the filters in the *AutoRoute*. When this happens, a *Route* is created with the configuration defined by the *AutoRoute*.

DDS inputs and outputs within an *AutoRoute* are defined using the XML tags `<dds_input>` and `<dds_output>`. Input and outputs from other data domains are defined using the tags `<input>` and `<output>`.

An *AutoTopicRoute* is a special kind of *AutoRoute* that defines a mapping between two DDS domains.

See the following tables for more information on allowable tags:

- Table 3.16 lists the tags allowed within a `<auto_route>`.
- Table 3.17 lists the tags allowed within a `<auto_topic_route>`.

### Table 3.16: AutoRoute Tag

<table>
<thead>
<tr>
<th>Tags within <code>&lt;auto_route&gt;</code></th>
<th>Description</th>
<th>Multiplicity</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;entity_monitoring&gt;</code></td>
<td>Enables and configures remote monitoring for the Session. See Section 5.</td>
<td>0..1</td>
</tr>
<tr>
<td><code>&lt;publish_with_original_timestamp&gt;</code></td>
<td>When this tag is true, the data samples read from the input stream are written into the output stream with the same timestamp that was associated with them when they were made available in the input domain. This option may not be applicable in some adapter implementations in which the concept of timestamp is unsupported. <strong>Default:</strong> false</td>
<td>0..1</td>
</tr>
</tbody>
</table>
| `<processor>`             | Sets a custom Processor for handling the data forwarding process. See Section 6. Attributes
  - **plugin_name:** Name of the plug-in that creates a Processor object. This name shall refer to a processor plug-in registered either in a `<plugin_library>` or with the service `attach_processor()` operation. | 0..1           |
| `<dds_input>`             | Only applicable to DDS inputs. Defines an input topic. | 0..*           |
| `<dds_output>`            | Only applicable to DDS outputs. Defines an output topic. | 0..*           |
| `<input>`                 | Only applicable to non-DDS inputs. Defines an input stream. | 0..*           |
| `<output>`                | Only applicable to non-DDS outputs. Defines an output stream. | 0..*           |
### Table 3.17: AutoTopicRoute Tag

<table>
<thead>
<tr>
<th>Tags within <code>&lt;auto_topic_route&gt;</code></th>
<th>Description</th>
<th>Multiplicity</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;entity_monitoring&gt;</code></td>
<td>Enables and configures remote monitoring for the Session. See Section 5.</td>
<td>0..1</td>
</tr>
<tr>
<td><code>&lt;publish_with_original_info&gt;</code></td>
<td>Writes the data sample as if they came from its original writer. Setting this option to true allows having redundant routing services and prevents the applications from receiving duplicate samples. <strong>Default:</strong> false</td>
<td>0..1</td>
</tr>
<tr>
<td><code>&lt;publish_with_original_timestamp&gt;</code></td>
<td>Indicates if the data samples are written with their original source timestamp. <strong>Default:</strong> false</td>
<td>0..1</td>
</tr>
<tr>
<td><code>&lt;propagate_dispose&gt;</code></td>
<td>Indicates whether or not disposed samples (NOT_ALIVE_DISPOSE) must be propagated by the TopicRoute. This action may be overwritten by the execution of a transformation. <strong>Default:</strong> true</td>
<td>0..1</td>
</tr>
<tr>
<td><code>&lt;propagate_unregister&gt;</code></td>
<td>Indicates whether or not disposed samples (NOT_ALIVE_NO_WRITERS) must be propagated by the TopicRoute. This action may be overwritten by the execution of a transformation. <strong>Default:</strong> true</td>
<td>0..1</td>
</tr>
<tr>
<td><code>&lt;topic_query_proxy&gt;</code></td>
<td>Configures the forwarding of TopicQueries. See Section 8 for detailed information on how Routing Service processes TopicQueries. The snippet below shows that topic query proxy is enabled in propagation mode, which causes the creation of a TopicQuery on the route’s input for each TopicQuery that an output’s matching DataReader creates. <strong>Example:</strong></td>
<td>0..1</td>
</tr>
<tr>
<td></td>
<td>&lt;topic_query_proxy&gt;</td>
<td></td>

3.5.9 Plugins

All the pluggable components specific to Routing Service are configured within the `<plugin_library>` tag. Table 3.20 describes the available tags.

Plug-ins are categorized and configured based on the source language. Routing Service supports C/C++ and Java plug-ins. See Section 6 for further information on developing Routing Service plug-ins.
Table 3.20: Configuration tags for plug-in libraries

<table>
<thead>
<tr>
<th>Tags within <code>&lt;plugin_library&gt;</code></th>
<th>Description</th>
<th>Multiplicity</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;adapter_plugin&gt;</code></td>
<td>Specifies a C/C++ Adapter plug-in. Attributes • name: uniquely identifies an Adapter plug-in within a library. This name qualified with the library name represents the plug-in registered name that is referred by <code>&lt;connection&gt;</code> tags. See Table 3.6.</td>
<td>0..*</td>
</tr>
<tr>
<td><code>&lt;java_adapter_plugin&gt;</code></td>
<td>Specifies a Java Adapter plug-in. Attributes (See <code>&lt;adapter_plugin&gt;</code>).</td>
<td>0..*</td>
</tr>
<tr>
<td><code>&lt;transformation_plugin&gt;</code></td>
<td>Specifies a C/C++ Transformation plug-in. Attributes • name: uniquely identifies a Transformation plug-in within a library. This name qualified with the library name represents the plug-in registered name that is referred by <code>&lt;transformation&gt;</code> tags. See Section 3.5.6.</td>
<td>0..*</td>
</tr>
<tr>
<td><code>&lt;processor_plugin&gt;</code></td>
<td>Specifies a C/C++ Processor plug-in. Attributes • name: uniquely identifies a Processor plug-in within a library. This name qualified with the library name represents the plug-in registered name that is referred by <code>&lt;processor&gt;</code> tags. See Section 3.5.6.</td>
<td>0..*</td>
</tr>
</tbody>
</table>

Table 3.21 and Table 3.22 describe the configuration of each different type of plug-in.

---

3.5. XML Tags for Configuring RTI Routing Service 41
Table 3.21: Configuration tags for C/C++ plug-ins.

<table>
<thead>
<tr>
<th>Tags within &lt;adapter_plugin&gt;, &lt;transformation_plugin&gt;, &lt;processor_plugin&gt;</th>
<th>Description</th>
<th>Multiplicity</th>
</tr>
</thead>
</table>
| <dll> | Shared library containing the implementation of the adapter plugin. This tag may specify the exact name of the file (for example, lib/libmyadapter.so) or a general name (no file extension). If no extension is provided, the path will be completed based on the running platform. For example, assuming a value for this tag of dir/myplugin:
  - UNIX-based systems: dir/libmyplugin.so
  - Windows systems: dir/myplugin.dll
If the library specified in this tag cannot be loaded (because the environment library path is not pointing to the path where the library is located), Routing Service will look for the library in <NDDSHOME>/lib/<architecture>. | 1 |
| <create_function> | This tag must contain the name of the function used to create the plugin instance. The function symbol must be present in the shared library specified in <dll>. | 1 |
| <property> | A sequence of name-value string pairs that allows you to configure the plug-in instance. **Example:**

```xml
<property>
  <value>
    <element>
      <name>myplugin.user_name</name>
      <value>myusername</value>
    </element>
  </value>
</property>
```

</table>

3.6 Enabling Distributed Logger

Routing Service provides integrated support for RTI Distributed Logger.

Distributed Logger is included in Connext DDS but it is not supported on all platforms; see the Connext DDS Core Libraries Platform Notes to see which platforms support Distributed Logger.

When you enable Distributed Logger, Routing Service will publish its log messages to Connext DDS. Then you can use RTI Admin Console to visualize the log message data. Since the data is provided in a topic, you can also use rtiddsspyspy or even write your own visualization tool.

To enable Distributed Logger, use the tag <distributed_logger> within <administration>. For example:

```xml
<routing_service name="default">
  <administration>
    ...
    <distributed_logger>
      <enabled>true</enabled>
    </distributed_logger>
  </administration>
  ...
</routing_service>
```

For the list of elements that configure Distributed Logger see Section 3.5.2. For more details about Distributed Logger, see Enabling Distributed Logger in RTI Services.

3.7 Support for Extensible Types

Routing Service includes partial support for the “Extensible and Dynamic Topic Types for DDS” specification <http://www.omg.org/spec/DDS-XTypes> from the Object Management Group (OMG). This section assumes that you are familiar with Extensible Types and you have read the Connext DDS Core Libraries Getting Started Guide Addendum for Extensible Types.
- *TopicRoutes* can subscribe to and publish topics associated with final and extensible types.

- You can select the type version associated with a topic route by providing the type description in the XML configuration file. The XML description supports structure inheritance. You can learn more about structure inheritance in the *Connext DDS Getting Started Guide Addendum for Extensible Types*.

- The TypeConsistencyEnforcementQosPolicy can be specified on a per-topic-route basis, in the same way as other QoS policies.

- Within a *DomainParticipant*, a topic cannot be associated with more than one type version. This prevents the same *DomainParticipant* from having two *Route DataReader* or *DataWriter* with different versions of a type for the same *Topic*. To achieve this behavior, create two different *DomainParticipant*, each associating the topic with a different type version.

The type declared in a *TopicRoute* input is the version that is passed to the output (or to a transformation). The *TopicRoute* can subscribe to different-but-compatible types, but those samples are translated to the *TopicRoute* input type.

### 3.7.1 Example: Samples Published by Two Writers of Type A and B, Respectively

```c
struct A {
    long x;
};

struct B {
    long x;
    long y;
};
```

<table>
<thead>
<tr>
<th>Samples published by two <em>DataWriters</em> of types A and B, respectively</th>
<th>Samples forwarded by a <em>TopicRoute</em> for type A in both input and output</th>
<th>Samples received by a B reader</th>
</tr>
</thead>
<tbody>
<tr>
<td>A (x=1)</td>
<td>A (x=1)</td>
<td>B (x=1, y=0)</td>
</tr>
<tr>
<td>B (x=10, y=11)</td>
<td>A (x=10)</td>
<td>B (x=10, y=0)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Samples published by two <em>DataWriters</em> of types A and B, respectively</th>
<th>Samples forwarded by a <em>TopicRoute</em> for type B in both input and output</th>
<th>Samples received by a B reader</th>
</tr>
</thead>
<tbody>
<tr>
<td>A (x=1)</td>
<td>B (x=1, y=0)</td>
<td>B (x=1, y=0)</td>
</tr>
<tr>
<td>B (x=10, y=11)</td>
<td>B (x=10, y=11)</td>
<td>B (x=10, y=11)</td>
</tr>
</tbody>
</table>

### 3.7. Support for Extensible Types
3.8 Support for RTI FlatData and Zero Copy Transfer Over Shared Memory

Routing Service supports communication with applications that use RTI FlatData™ and Zero-Copy transfer over shared memory, only on the subscription side.

**Warning:** On the publication side, Routing Service will ignore the type annotations for these capabilities and will communicate through the regular serialization and deserialization paths.

To enable Routing Service to work with RTI FlatData and Zero-copy transfer over shared memory, you will need to manually define the type in the XML configuration with the proper annotations, and then register this type manually in each DomainParticipant. You can use each of these capabilities separately or together.

For further information about these capabilities, see the Sending Large Data section in the RTI Connext DDS User’s Manual.

3.8.1 Example: Configuration to enable both FlatData and zero-copy transfer over shared memory

```xml
<dds>
  <types>
    <struct name="Point"
      transferMode="shmem_ref"
      languageBinding="flat_data"
      extensibility="final">
      <member name="x" type="long"/>
      <member name="y" type="long"/>
    </struct>
  </types>

  <qos_library name="MyQosLib">
    <qos_profile name="ShmemOnly">
      <participant_qos>
        <discovery>
          <initial_peers>
            <element>shmem://</element>
          </initial_peers>
        </discovery>
        <transport_builtin>
          <mask>SHMEM</mask>
        </transport_builtin>
      </participant_qos>
    </qos_profile>
  </qos_library>
</dds>
```

(continues on next page)
<routing_service name="FlatDataWithZeroCopy">
  <domain_route>
    <participant name="InputDomain">
      <domain_id>0</domain_id>
      <participant_qos base_name="MyQosLib::ShmemOnly"/>
      <registered_type name="Point" type_name="Point"/>
    </participant>
    <participant name="OutputDomain">
      <domain_id>1</domain_id>
      <registered_type name="Point" type_name="Point"/>
    </participant>
  </domain_route>
  <session>
    <topic_route>
      <input participant="InputDomain">
        <topic_name>PointTopic</topic_name>
        <registered_type_name>Point</registered_type_name>
      </input>
      <output participant="OutputDomain">
        <topic_name>PointTopic</topic_name>
        <!-- The output will ignore the FlataData and Zero Copy capabilities -->
        <registered_type_name>Point</registered_type_name>
      </output>
    </topic_route>
  </session>
</routing_service>

3.8. Support for RTI FlatData and Zero Copy Transfer Over Shared Memory
Chapter 4

Remote Administration

This section provides documentation on Routing Service remote administration.

**Note:** Routing Service remote administration is based on the RTI Remote Administration Platform described in Section 11.2. We recommend that you read that section before using Routing Service remote administration.

Below you will find an API reference for all the supported operations.

### 4.1 Overview

#### 4.1.1 Enabling Remote Administration

By default, remote administration is disabled in Routing Service. To enable remote administration, you can use the `<administration>` tag (see Section 3.5.1) or the `-remoteAdministrationDomainId` command-line parameter, which enables remote administration and sets the domain ID for remote communication (see Section 2.1).

#### 4.1.2 Available Service Resources

Table 4.1 lists the public resources specific to Routing Service. Each resource identifier is expressed as a hierarchical sequence of identifiers, including parent and target resources. (See Section 11.1.1 for details.)

In the table below, the elements (rs), (dr), (c), (s), (ar), (r), (i), and (o) refer to the name of an entity of the corresponding class as specified in the configuration in the name attribute. For example, in the following configuration:

```xml
<routing_service name="MyRouter">...</routing_service>
```

The resource identifier is:

```
/routing_services/MyRouter
```
In the table, the resource identifier is written as /routing_services/(rs), where (rs) is the routing service name, (dr) is the domain route name, and so on. This nomenclature is used in the table to give you an idea of the structure of the resource identifiers. For actual (example) resource identifier names, see the example section that follows.

Table 4.1: Resources and Their Identifiers in Routing Service

<table>
<thead>
<tr>
<th>Resource</th>
<th>Resource Identifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>RoutingService</td>
<td>/routing_services/(rs)</td>
</tr>
<tr>
<td>DomainRoute</td>
<td>/routing_services/(rs)/domain_routes/(dr)</td>
</tr>
<tr>
<td>Connection or Participant</td>
<td>/routing_services/(rs)/domain_routes/(dr)/connections/(c)</td>
</tr>
<tr>
<td>Session</td>
<td>/routing_services/(rs)/domain_routes/(dr)/sessions/(s)</td>
</tr>
<tr>
<td>AutoRoute or AutoTopicRoute</td>
<td>/routing_services/(rs)/domain_routes/(dr)/sessions/(s)/auto_routes/(ar)</td>
</tr>
<tr>
<td>Route or TopicRoute</td>
<td>/routing_services/(rs)/domain_routes/(dr)/sessions/(s)/routes/(r)</td>
</tr>
<tr>
<td>Route Input or DDS Input</td>
<td>/routing_services/(rs)/domain_routes/(dr)/sessions/(s)/routes/(r)/inputs/(i)</td>
</tr>
<tr>
<td>Route Output or DDS Output</td>
<td>/routing_services/(rs)/domain_routes/(dr)/sessions/(s)/routes/(r)/outputs/(i)</td>
</tr>
</tbody>
</table>

Example

This example shows you how to address a resource of each possible resource class in Routing Service, using the example configuration in Section 4.3 as a reference. (For a complete reference of the available configuration tags used in Routing Service, see Section 3.5.)

RoutingService

Entity with name “MyRouter”:

```xml
<routing_service name="MyRouter">...</routing_service>
```

Resource identifier:

```
/routing_services/MyRouter
```

DomainRoute

Entity with name “MyDomainRoute” in parent “MyRouter”:

```xml
<routing_service name="MyRouter">
  <domain_route name="MyDomainRoute">...</domain_route>
</routing_service>
```

Resource identifier:
Participant
Entity with name “MyParticipant” in parent “MyDomainRoute”:

```
<routing_service name="MyRouter">
  <domain_route name="MyDomainRoute">
    <participant name="Session">...</participant>
  </domain_route>
</routing_service>
```

Resource identifier:

```
/routing_services/MyRouter/domain_routes/MyDomainRoute/connections/MyParticipant
```

Session
Entity with name “MySession” in parent “MyDomainRoute”:

```
<routing_service name="MyRouter">
  <domain_route name="MyDomainRoute">
    <session name="MySession">...</session>
  </domain_route>
</routing_service>
```

Resource identifier:

```
/routing_services/MyRouter/domain_routes/MyDomainRoute/sessions/MySession
```

AutoTopicRoute (or AutoRoute)
Entity with name “MyAutoTopicRoute” in parent “MySession”:

```
<routing_service name="MyRouter">
  <domain_route name="MyDomainRoute">
    <session name="MySession">
      <auto_topic_route name="MyAutoTopicRoute">...</auto_topic_route>
    </session>
  </domain_route>
</routing_service>
```

Resource identifier (all on one line):

```
/routing_services/MyRouter/domain_routes/MyDomainRoute/sessions/MySession/routes/MyAutoTopicRoute
```
**TopicRoute (or Route)**

Entity with name “MyTopicRoute” in parent “MySession”:

```xml
<routing_service name="MyRouter">
    <domain_route name="MyDomainRoute">
        <session name="MySession">
            <topic_route name="MyTopicRoute">...
        </session>
    </domain_route>
</routing_service>
```

Resource identifier (all on one line):

```
/routing_services/MyRouter/domain_routes/MyDomainRoute/sessions/MySession/
routes/MyTopicRoute
```

**Input**

Entity with name “MyInput” in parent “MyTopicRoute”:

```xml
<routing_service name="MyRouter">
    <domain_route name="MyDomainRoute">
        <session name="MySession">
            <topic_route name="MyTopicRoute">
                <input name="MyInput">...
            </input>
        </session>
    </domain_route>
</routing_service>
```

Resource identifier (all on one line):

```
/routing_services/MyRouter/domain_routes/MyDomainRoute/sessions/MySession/
routes/MyRoute/inputs/MyInput
```

**Output**

Entity with name “MyOutput” in parent “MyTopicRoute”:

```xml
<routing_service name="MyRouter">
    <domain_route name="MyDomainRoute">
        <session name="MySession">
            <topic_route name="MyTopicRoute">
                <output name="MyOutput">...
            </output>
        </session>
    </domain_route>
</routing_service>
```

Resource identifier (all on one line):
### 4.1.3 Resource Object Representations

Table 4.2: Resource Representations in Routing Service

<table>
<thead>
<tr>
<th>Resource Representation</th>
<th>Format (all element type definitions are from the file rti_routing_service.xsd)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ddsObjectRepresentation</td>
<td><code>&lt;xs:element name=&quot;dds&quot; type=&quot;ddsRouter&quot;/&gt;</code></td>

4.2 API Reference

This section documents each remote operation, organized by service resource class.

4.2.1 Remote API Overview

Note: To improve readability, `<SERVICE>` is sometimes used in place of the service resource portion of the resource identifier (e.g., `/routing_services/(rs)` or `/routing_services/MyService`). It does not represent valid syntax.

Table 4.3: Remote Interface Overview

<table>
<thead>
<tr>
<th>Resource</th>
<th>Operation</th>

4.2.2 Service

CREATE /routing_services/(rs)/domain_routes

Operation create_domain_route

Creates a DomainRoute object from its domainRouteObjectRepresentation (see Table 4.2).

See Create Resource (Section 11.2.3).

- Example

Create a DomainRoute with name “NewDomainRoute” under RoutingService “MyRouter”, with its configuration provided as a str:// scheme.

<table>
<thead>
<tr>
<th>Request Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>CREATE</td>
</tr>
<tr>
<td>resource_identifier</td>
<td>/routing_services/MyRouter/domain_routes</td>
</tr>
<tr>
<td>string_body</td>
<td>str://&quot;&lt;domain_route name=&quot;NewDomainRoute&quot;&gt; ... &lt;/domain_route&gt;&quot;</td>
</tr>
</tbody>
</table>

The newly created object has the resource identifier:

/routing_services/MyRouter/domain_routes/NewDomainRoute

CREATE /routing_services/(rs)/config

Operation load

Loads a new configuration for the service from its ddsObjectRepresentation (see Table 4.2).

If the RoutingService is already loaded, this operation will unload it first.

4.2. API Reference
The provided configuration must contain a valid RoutingService configuration with the same name that the initial configuration used when the service was first instantiated.

If the operation fails, the service will remain in an unloaded state.

**Request body**
- **string_body**: a valid RoutingService XML configuration document provided as file:// or str://.

**Reply body**
- Empty.

**Example**

Load a new configuration in RoutingService “MyRouter”.

<table>
<thead>
<tr>
<th>Request Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>CREATE</td>
</tr>
<tr>
<td>resource_identifier</td>
<td>/routing_services/MyRouter/config</td>
</tr>
</tbody>
</table>
| string_body         | str://"<dds>...
<qos_library name="QosLibrary">...
</qos_library>
...
<routi
ng_service name="MyRouter">...
</routing_service>
</dds>"

**GET /routing_services/(rs)**

**Operation**: get

Returns a snapshot of the currently loaded full XML configuration as ddsObjectRepresentation (see Table 4.2).

See Get Resource (Section 11.2.3).

- Example reply body:
  
  <routing_service name="MyRouter">
    <administration>...</administration>
    ...
  </routing_service>
UPDATE /routing_services/(rs)
Operation: update

Updates the specified RoutingService object.

See Update Resource (Section 11.2.3).

The expected XML configuration is a subset of routerObjectRepresentation and contains only parameters valid for the update.

- Example

  Update a RoutingService with the name “MyRouter”.

<table>
<thead>
<tr>
<th>Request Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>CREATE</td>
</tr>
<tr>
<td>resource_identifier</td>
<td>/routing_services/MyRouter</td>
</tr>
<tr>
<td>string_body</td>
<td>str://&quot;&lt;routing_service&gt;</td>
</tr>
<tr>
<td></td>
<td>...</td>
</tr>
<tr>
<td></td>
<td>&lt;/routing_service&gt;&quot;</td>
</tr>
</tbody>
</table>

UPDATE /routing_services/(rs)/state
Operation: set_state

Sets the state of a RoutingService object.

See Set Resource State (Section 11.2.3).

Valid requested states:
- STARTED
- STOPPED
- PAUSED
- RUNNING

- Example

  Enable a RoutingService with the name “MyRouter”.

<table>
<thead>
<tr>
<th>Request Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>UPDATE</td>
</tr>
<tr>
<td>resource_identifier</td>
<td>/routing_services/MyRouter/state</td>
</tr>
<tr>
<td>octet_body</td>
<td>to_cdr_buffer(RTI::Service::EntityStateKind::ENABLED)</td>
</tr>
</tbody>
</table>
UPDATE /routing_services/(rs):save
  Operation: save

  Dumps the currently loaded XML configuration into a file.

  The output file is specified by the save_path configuration tag. The save operation will fail if the save_path has not been configured.

  Request body
  - Empty.

  Reply body
  - Empty.

DELETE /routing_services/(rs)/domain_routes/(dr)
  Operation delete_domain_route

  Deletes the specified DomainRoute.

  See Delete Resource (Section 11.2.3).

DELETE /routing_services/(rs)/config
  Operation unload

  Unloads the current configuration of the service. If the RoutingService is enabled, this operation will disable it first. Upon a successful request, the service will remain in an unloaded state and no other operations can be made until a configuration is loaded.

  Request body
  - Empty.

  Reply body
  - Empty.

DELETE /routing_services/(rs)
  Operation shutdown

  Initiates the shutdown sequence on the process where the RoutingService object runs.

  - If RoutingService runs as a process executed by the shipped executable in the RTI Connext DDS installation, the process will exit upon receipt of the command.

  - If RoutingService is instantiated as a library in your application, the service instance will notify the installed remote shutdown hook.

  In both cases, right before executing the shutdown sequence, RoutingService will send a reply indicating the result of the operation. Note that if the operation returns successfully, the reply may be lost and never received by remote clients, since all the contained entities are deleted, including the RTI Remote Administration Platform entities.
This operation can be invoked at any time during the lifecycle of the service.

**Request body**
- Empty.

**Reply body**
- Empty.

### 4.2.3 DomainRoute

**CREATE** `/routing_services/(rs)/domain_routes/(dr)/sessions`

**Operation:** `create_session`

Creates a `Session` object from its `sessionObjectRepresentation` (see Table 4.2).

See `Create Resource` (Section 11.2.3).

- **Example**

  Create a `Session` with the name “NewSession” under the `DomainRoute` “MyDomainRoute”, with its configuration provided as a `str://` scheme.

<table>
<thead>
<tr>
<th>Request Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>action</code></td>
<td>CREATE</td>
</tr>
<tr>
<td><code>resource_identifier</code></td>
<td>/routing_services/MyRouter/domain_routes/MyDomainRoute/sessions</td>
</tr>
</tbody>
</table>
| `string_body`       | `str://"<session name="NewSession">...

The newly created object has the resource identifier:

```
<SERVICE>/domain_routes/NewDomainRoute/sessions/NewSession
```

**UPDATE** `/routing_services/(rs)/domain_routes/(dr)`

**Operation:** `update`

Updates the specified `DomainRoute` object.

See `Update Resource` (Section 11.2.3).

The expected XML configuration is a subset of `domainRouteObjectRepresentation` and contains only parameters valid for the update.

- **Example**

  Update a `DomainRoute` with the name “MyDomainRoute” under the `RoutingService` “MyRouter”, with its configuration provided as a `str://` scheme.
<table>
<thead>
<tr>
<th>Request Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>CREATE</td>
</tr>
<tr>
<td>resource_identifier</td>
<td>/routing_services/MyRouter/domain_routes/My-Route</td>
</tr>
</tbody>
</table>
| string_body        | str://"<domain_route> ...
</domain_route>"                                                          |

**UPDATE /routing_services/(rs)/domain_routes/(dr)/state**

**Operation**: set_state

Sets the state of a DomainRoute object.

See **Set Resource State** (Section 11.2.3).

Valid requested states:

- ENABLED
- DISABLED

- Example

Enable a DomainRoute with the name “MyDomainRoute” under the RoutingService “MyRouter”.

<table>
<thead>
<tr>
<th>Request Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>UPDATE</td>
</tr>
<tr>
<td>resource_identifier</td>
<td>/routing_services/MyRouter/domain_routers/My-Route/state</td>
</tr>
<tr>
<td>octet_body</td>
<td>to_cdr_buffer(RTI::Service::EntityStateKind::ENABLED)</td>
</tr>
</tbody>
</table>

**DELETE /routing_services/(rs)/domain_routes/(dr)/sessions/(s)**

**Operation**: delete_session

Deletes the specified Session.

See **Delete Resource** (Section 11.2.3).

**Request body**

- Empty.

**Reply body**

- Empty.
### 4.2.4 Connection

**UPDATE <SERVICE>/domain_routes/(dr)/connections/(c):add_peer**

**Operation add_peer**

Adds a list of peers to the specified Connection.

The Connection implementation shall refer to a <participant> object.

**Request body**

- **string_body**: A comma-separated list of peer descriptors, as described in peer descriptor format.

- Example peer descriptor list:

  ```
  udpv4://10.2.0.1,udpv4://239.255.0.1
  ```

**Reply body**

- Empty.

**UPDATE <SERVICE>/domain_routes/(dr)/connections/(c)**

**Operation: update**

Updates the specified Connection object.

See Update Resource (Section 11.2.3).

The expected XML configuration is a subset of connectionObjectRepresentation or participantObjectRepresentation, and contains only parameters valid for the update.

- Example

  Update a Connection with the name “MyConnection” under the DomainRoute “MyDomainRoute”, with its configuration provided as a str:// scheme.

<table>
<thead>
<tr>
<th>Request Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>CREATE</td>
</tr>
<tr>
<td>resource_identifier</td>
<td>/routing_services/MyRouter/domain_routes/MyDomainRoute/connections/MyConnection</td>
</tr>
<tr>
<td>string_body</td>
<td>str://&quot;&lt;connection&gt; ... &lt;/connection&gt;&quot;</td>
</tr>
</tbody>
</table>

**UPDATE <SERVICE>/domain_routes/(dr)/connections/(c):remove_peer**

**Operation remove_peer**

Removes a list of peers from the specified Connection.

The Connection implementation shall refer to a <participant> object.
Request body

- **string_body**: A comma-separated list of peer descriptors, as described in peer descriptor format.

Example peer descriptor list:

```
updv4://10.2.0.1,udpv4://239.255.0.1
```

Reply body

- Empty.

### 4.2.5 Session

**CREATE <SERVICE>/domain_routes/(dr)/sessions/(s)/auto_routes**

Operation: `create_auto_route`

Creates an *AutoRoute* or *AutoTopicRoute* object from its *autoRouteObjectRepresentation* or *autoTopicRouteObjectRepresentation* (see Table 4.2).

See *Create Resource* (Section 11.2.3).

Example

Create an *AutoRoute* with the name “NewAutoRoute” under the *Session* “MySession”, with its configuration provided as a `str://` scheme.

<table>
<thead>
<tr>
<th>Request Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>action</strong></td>
<td>CREATE</td>
</tr>
<tr>
<td><strong>resource_identifier</strong></td>
<td>/routing_services/MyRouter/domain_routes/MyDomainRoute/sessions/MySession/auto_routes</td>
</tr>
<tr>
<td><strong>string_body</strong></td>
<td><code>str://&quot;&lt;auto_route name=&quot;NewAutoRoute&quot;&gt; ... &lt;/auto_route&gt;&quot;</code></td>
</tr>
</tbody>
</table>

The newly created object has the resource identifier:

```
/routing_services/MyRouter/domain_routes/MyDomainRoute/sessions/MySession/auto_routes/NewAutoRoute
```

**CREATE <SERVICE>/domain_routes/(dr)/sessions/(s)/routes**

Operation: `create_route`

Creates a *Route* or *TopicRoute* object from its *routeObjectRepresentation* or *topicRouteObjectRepresentation* (see Table 4.2).

See *Create Resource* (Section 11.2.3).

Example
Create a Route with the name “NewRoute” under the Session “MySession”, with its configuration provided as a str:// scheme.

<table>
<thead>
<tr>
<th>Request Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>CREATE</td>
</tr>
<tr>
<td>resource_identifier</td>
<td>/routing_services/MyRouter/domain_routes/MyDomainRoute/ sessions/MySession/routes</td>
</tr>
<tr>
<td>string_body</td>
<td>str://&quot;&lt;route name=&quot;NewRoute&quot;&gt;...&lt;route&gt;&quot;</td>
</tr>
</tbody>
</table>

The newly created object has the resource identifier:

```
/routing_services/MyRouter/domain_routes/MyDomainRoute/sessions/MySession/routes/NewRoute
```

**UPDATE <SERVICE>/domain_routes/(dr)/sessions/(s)**

**Operation:** update

Updates the specified Session object.

See Update Resource (Section 11.2.3).

The expected XML configuration is a subset of sessionObjectRepresentation and contains only parameters valid for update.

- **Example**

  Update a Session with the name “MySession” under the DomainRoute “MyDomainRoute”, with its configuration provided as a str:// scheme.

<table>
<thead>
<tr>
<th>Request Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>CREATE</td>
</tr>
<tr>
<td>resource_identifier</td>
<td>/routing_services/MyRouter/domain_routes/MyDomainRoute/ sessions/MySession</td>
</tr>
<tr>
<td>string_body</td>
<td>str://&quot;&lt;session&gt;...&lt;session&gt;&quot;</td>
</tr>
</tbody>
</table>

**UPDATE <SERVICE>/domain_routes/(dr)/sessions/(s)/state**

**Operation:** set_state

Sets the state of a Session object.
See *Set Resource State* (Section 11.2.3).

Valid requested states:

- **ENABLED**
- **DISABLED**

- Example

Enable a *Session* with the name “MySession” under the *DomainRoute* “MyDomainRoute”.

<table>
<thead>
<tr>
<th>Request Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>UPDATE</td>
</tr>
<tr>
<td>resource_identifier</td>
<td>/routing_services/MyRouter/domain_routers/MyDomainRoute/sessions/MySession/state</td>
</tr>
<tr>
<td>octet_body</td>
<td>to_cdr_buffer(RTI::Service::EntityStateKind::ENABLED)</td>
</tr>
</tbody>
</table>

**DELETE <SERVICE>/domain_routes/(dr)/sessions/(s)/auto_routes/(ar)**

*Operation delete_auto_route*

Deletes the specified *AutoRoute*.

See *Delete Resource* (Section 11.2.3).

**DELETE <SERVICE>/domain_routes/(dr)/sessions/(s)/routes/(r)**

*Operation delete_route*

Deletes the specified *Route*.

See *Delete Resource* (Section 11.2.3).

### 4.2.6 AutoRoute

**UPDATE <SERVICE>/domain_routes/(dr)/sessions/(s)/auto_routes/(ar)**

*Operation: update*

Updates the specified *AutoRoute* or *AutoTopicRoute* object.

See *Update Resource* (Section 11.2.3).

The expected XML configuration is a subset of `autoRouteObjectRepresentation` or `autoTopicRouteObjectRepresentation`, and contains only parameters valid for the update.

- Example
Update an *AutoRoute* with the name “MyAutoRoute” under the *Session* “My-Session”, with its configuration provided as a `str://` scheme.

<table>
<thead>
<tr>
<th>Request Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>CREATE</td>
</tr>
</tbody>
</table>
| resource_identifier | /routing_services/MyRouter/domain_routes/MyDomainRoute/sessions/My-
|                   |   Session/auto_routes/MyAutoRoute                                       |
| string_body       | `str://"<auto_route>`                                                   |
|                   | ...                                                                      |
|                   | `</auto_route>"`                                                         |

UPDATE `<SERVICE>/domain_routes/(dr)/sessions/(s)/auto_routes/(ar)/state`

**Operation**: `set_state`

Sets the state of an *AutoRoute* object.

See *Set Resource State* (Section 11.2.3).

Valid requested states:
- **ENABLED**
- **DISABLED**
- **RUNNING**
- **PAUSED**

- Example

  Pause an *AutoRoute* with the name “MyAutoRoute” under the *Session* “My-Session”.

<table>
<thead>
<tr>
<th>Request Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>UPDATE</td>
</tr>
</tbody>
</table>
| resource_identifier | /routing_services/MyRouter/domain_routers/MyDomainRoute/sessions/My-
|                   |   Session/auto_routes/MyAutoRoute/state                                |
| octet_body        | `to_cdr_buffer(RTI::Service::EntityStateKind::PAUSED)`                |

4.2.7 Route

UPDATE `<SERVICE>/domain_routes/(dr)/sessions/(s)/routes/(r)`

**Operation**: `update`

See *Update Resource* (Section 11.2.3).
The expected XML configuration is a subset of routeObjectRepresentation or topicRouteObjectRepresentation, and contains only parameters valid for the update.

- Example

  Update a Route with the name “MyRoute” under the Session “MySession”, with its configuration provided as a str:// scheme.

<table>
<thead>
<tr>
<th>Request Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>CREATE</td>
</tr>
<tr>
<td>resource_identifier</td>
<td>/routing_services/MyRouter/domain_routes/MyDomainRoute/sessions/MySession/routes/MyRoute</td>
</tr>
<tr>
<td>string_body</td>
<td>str://&quot;&lt;route&gt; ... &lt;/route&gt;&quot;</td>
</tr>
</tbody>
</table>

UPDATE <SERVICE>/domain_routes/(dr)/sessions/(s)/routes/(r)/state

Operation: set_state

Sets the state of a Route object.

See Set Resource State (Section 11.2.3).

Valid requested states:
- ENABLED
- DISABLED
- RUNNING
- PAUSED

- Example

  Pause a Route with the name “MyRoute” under the Session “MySession”.

<table>
<thead>
<tr>
<th>Request Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>UPDATE</td>
</tr>
<tr>
<td>resource_identifier</td>
<td>/routing_services/MyRouter/domain_routers/MyDomainRoute/ sessions/MySession/routes/MyRoute</td>
</tr>
<tr>
<td>octet_body</td>
<td>to_cdr_buffer(RTI::Service::EntityStateKind::PAUSED)</td>
</tr>
</tbody>
</table>
4.2.8 Input/Output

**UPDATE <SERVICE>/domain_routes/(dr)/sessions/(s)/routes/(r)/inputs(i)**

Operation: update

See Update Resource (Section 11.2.3).

The expected XML configuration is a subset of `routeInputObjectRepresentation` or `topicRouteInputObjectRepresentation`, and contains only parameters valid for the update.

- Example

  Update Input with the name “MyInput” under the Route “MyRoute”, with its configuration provided as a `str://` scheme.

<table>
<thead>
<tr>
<th>Request Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>CREATE</td>
</tr>
<tr>
<td>resource_identifier</td>
<td>/routing_services/MyRouter/domain_routes/My-DomainRoute/ sessions/MySession/routes/My-Route/inputs/MyInput</td>
</tr>
<tr>
<td>string_body</td>
<td><code>str://&quot;&lt;input&gt;</code></td>
</tr>
<tr>
<td></td>
<td><code>...</code></td>
</tr>
<tr>
<td></td>
<td><code>&lt;/input&gt;&quot;</code></td>
</tr>
</tbody>
</table>

**UPDATE <SERVICE>/domain_routes/(dr)/sessions/(s)/routes/(r)/outputs(i)**

Operation: update

See Update Resource (Section 11.2.3).

The expected XML configuration is a subset of `routeOutputObjectRepresentation` or `topicRouteOutputObjectRepresentation`, and contains only parameters valid for the update.

- Example

  Update Output with the name “MyOutput” under the Route “MyRoute”, with its configuration provided as a `str://` scheme.

<table>
<thead>
<tr>
<th>Request Field</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>CREATE</td>
</tr>
<tr>
<td>resource_identifier</td>
<td>/routing_services/MyRouter/domain_routes/My-DomainRoute/ sessions/MySession/routes/My-Route/outputs/MyOutput</td>
</tr>
<tr>
<td>string_body</td>
<td><code>str://&quot;&lt;output&gt;</code></td>
</tr>
<tr>
<td></td>
<td><code>...</code></td>
</tr>
<tr>
<td></td>
<td><code>&lt;/output&gt;&quot;</code></td>
</tr>
</tbody>
</table>
4.3 Example: Configuration Reference

This configuration example shows how individual commands would apply to a valid Routing Service configuration.

```xml
<?xml version="1.0"?>
<dds>
  <routing_service name="MyRouter">
    <domain_route name="MyDomainRoute">
      <participant name="MyParticipant">
        <domain_id>0</domain_id>
      </participant>
      <connection name="MyConnection">
        <!-- other connections/participants -->
      </connection>
    </domain_route>
    <session name="MySession">
      <auto_route name="MyAutoRoute">
        <publish_with_original_timestamp>true</publish_with_original_timestamp>
        <input name="MyInput">
          <property>
          ...
          </property>
        </input>
        <output name="MyOutput">
          <property>
          ...
          </property>
        </output>
      </auto_route>
      <auto_topic_route name="MyAutoTopicRoute">
        <publish_with_original_info>true</publish_with_original_info>
        <input name="MyInput">
          <datareader_qos>
          ...
          </datareader_qos>
        </input>
        <output name="MyOutput">
          <datawriter_qos>
          ...
          </datawriter_qos>
        </output>
      </auto_topic_route>
      ... <!-- other auto (Topic) routes -->
    </session>
  </routing_service>
</dds>
```

(continues on next page)
...<property>
  ...
</property>
</input>
...
<!-- other inputs -->
<output name="MyOutput">
  ...
  <property>
  ...
</property>
</output>
...
<!-- other outputs -->
</route>
...
<!-- other (Topic) routes -->
<topic_route name="MyTopicRoute">
  <route_types>true</route_types>
  ...
  <input name="MyInput">
    ...
    <datareader_qos>
      ...
    </datareader_qos>
  </input>
  ...
  <output name="MyOutput">
    ...

      ...
    </datawriter_qos>
  </output>
  ...
</topic_route>
</session>
...
<!-- other sessions -->
</domain_route>
...
<!-- other domain routes -->
</routing_service>
</dds>
Chapter 5

Monitoring

This section provides documentation on Routing Service remote monitoring.

Note: Routing Service monitoring is based on the Monitoring Distribution Platform described in Section 11.3. We recommend that you read Section 11.3 before using Routing Service monitoring.

5.1 Overview

5.1.1 Enabling Service Monitoring

By default, monitoring is disabled in Routing Service. To enable monitoring you can use the <monitoring> tag (see Section 3.5.1) or the -remoteMonitoringDomainId command-line parameter, which enables remote monitoring and sets the domain ID for data publication (see Section 2.1).

5.1.2 Monitoring Types

The available Keyed Resource classes and their types that can be present in the distribution monitoring topics are listed in Table 5.1. The complete type relationship is shown in Figure 5.1.

<table>
<thead>
<tr>
<th>Keyed Resource Class</th>
<th>Config</th>
<th>Event</th>
<th>Periodic</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service</td>
<td>ServiceConfig</td>
<td>ServiceEvent</td>
<td>ServicePeriodic</td>
</tr>
<tr>
<td>DomainRoute</td>
<td>DomainRouteConfig</td>
<td>DomainRouteEvent</td>
<td>DomainRoutePeriodic</td>
</tr>
<tr>
<td>Session</td>
<td>SessionConfig</td>
<td>SessionEvent</td>
<td>SessionPeriodic</td>
</tr>
<tr>
<td>AutoRoute/AutoTopicRoute</td>
<td>AutoRouteConfig</td>
<td>AutoRouteEvent</td>
<td>AutoRoutePeriodic</td>
</tr>
<tr>
<td>Route/TopicRoute</td>
<td>RouteConfig</td>
<td>RouteEvent</td>
<td>RoutePeriodic</td>
</tr>
<tr>
<td>Input</td>
<td>InputConfig</td>
<td>InputEvent</td>
<td>InputPeriodic</td>
</tr>
<tr>
<td>Output</td>
<td>OutputConfig</td>
<td>OutputEvent</td>
<td>OutputPeriodic</td>
</tr>
</tbody>
</table>

All the type definitions for Routing Service monitoring information are in [NDDSHOME]/resource/
Routing Service creates a DataWriter for each distribution Topic. All DataWriters are created from a single Publisher, which is created from a dedicated DomainParticipant. See Section 3.5.1 for details on configuring the QoS for these entities.

5.2 Monitoring Metrics Reference

This section provides a reference to all the monitoring metrics Routing Service distributes, organized by service resource class.

5.2.1 Service

Listing 5.1: Routing Service Types

```cpp
@mutable @nested
struct ServiceConfig : Service::Monitoring::EntityConfig {
    BoundedString application_name;
    Service::Monitoring::ResourceGuid application_guid;
    @optional Service::Monitoring::HostConfig host;
    @optional Service::Monitoring::ProcessConfig process;
};

@mutable @nested
struct ServiceEvent : Service::Monitoring::EntityEvent {
```
5.2.2 DomainRoute

Listing 5.2: DataReader Types

```csharp
@mutable @nested
struct ConnectionConfigInfo {
    BoundedString name;
    AdapterClassKind class;
}
```

5.2. Monitoring Metrics Reference 71
BoundedString plugin_name;
XmlString configuration;
};

mutable @nested
struct ConnectionEventInfo {
    BoundedString name;
    @optional Service::BuiltinTopicKey participant_key;
};

mutable @nested
struct DomainRouteConfig : Service::Monitoring::EntityConfig {
    @optional sequence<ConnectionConfigInfo> connections;
};

mutable @nested
struct DomainRouteEvent : Service::Monitoring::EntityEvent {
    @optional sequence<ConnectionEventInfo> connections;
};

mutable @nested
struct DomainRoutePeriodic {
    @optional Service::Monitoring::StatisticVariable in_samples_per_sec;
    @optional Service::Monitoring::StatisticVariable in_bytes_per_sec;
    @optional Service::Monitoring::StatisticVariable out_samples_per_sec;
    @optional Service::Monitoring::StatisticVariable out_bytes_per_sec;
    @optional Service::Monitoring::StatisticVariable latency_millisec;
};

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Inherited fields from EntityConfig</td>
<td>See Table 11.13.</td>
</tr>
<tr>

| samples_per_sec | Statistic variable that provides information about the samples per second provided by this input/output:  
• If the resource is Input, this field provides the value of the samples returned by the underlying StreamReader::read() operation.  
• If the resource is Output, this field provides the value of the samples provided to the underlying StreamWriter::write() operation. |
| bytes_per_sec   | Statistic variable that provides information about the bytes per second provided by this input/output. The bytes refer only to the serialized samples, excluding protocol headers (RTPS, UDP, etc). |

$^{1}$ The throughput measured in bytes can only be computed if the samples are DynamicData samples. If not, only the throughput, measured in samples per second, is available. This statement applies to all the statistic variables described in this chapter that measure throughput in bytes per second.

Chapter 6

Software Development Kit

You can extend the out-of-the-box behavior of Routing Service through its Software Development Kit (SDK). The SDK provides a set of public interfaces that allow you to control Routing Service execution as well as extend its capabilities.

The SDK is divided in the following modules:

- **RTI Routing Service Service API:** This module offers a set of APIs that allow you to instantiate Routing Service instances in your application. This allows you to run Routing Service as a library, as described in Section 2.2.

- **RTI Routing Service Adapter API:** Adapters are pluggable components that allow Routing Service to consume and produce data for different data domains (e.g., Connext DDS, MQTT, raw Socket, etc.). This module offers a set of pluggable APIs to develop custom Adapters, which you can use through shared libraries or through the Service API. By default, Routing Service is distributed with a builtin DDS adapter that is part of the service library.

- **RTI Routing Service Processor API:** Processors are event-oriented pluggable components that allow you to control the forwarding process that occurs within a Route. This module offers a set of pluggable APIs to develop custom Processors, which you can use through shared libraries or through the Service API.

- **RTI Routing Service Transformation API:** Transformations are data-oriented pluggable components that allow you to perform conversions of the representation and content of the data that goes through Routing Service. This module offers a set of pluggable APIs to develop custom Transformations, which you can use through shared libraries or through the Service API.

Table 6.1 shows which modules are available for each API, along with links to the API documentation.

Chapter 7

Propagating Content Filters

_**Routing Service**_ can be configured to propagate the content filter information associated with user _DataReaders_ to the user _DataWriters_.

When this functionality is enabled, the user _DataWriters_ receive information about the data sets subscribed to by the user _DataReaders_. The _DataWriters_ can use that information to do writer-side filtering\(^1\) and propagate only the samples belonging to the subscribed data sets. This results in more efficient bandwidth usage as well as in less CPU consumption in the _Routing Service_ instances and user _DataReaders_.

Figure 7.1 shows a scenario where communication between _DataWriters_ and _DataReaders_ is relayed through one or more _Routing Services_ that do not propagate content filters. The user _DataWriters_ will send on the wire all the samples they publish, since they cannot make assumptions about what the user _DataReaders_ want. This default behavior incurs unnecessary bandwidth and CPU utilization since the filtering will occur on the DDS _DataWriter SW\(_N\)._

Enabling filter propagation makes it possible to perform writer-side filtering from the user _DataWriters_, since they receive a composed filter that represents the data set subscribed to by all the user _DataReaders_, as shown in Figure 7.2.

### 7.1 Enabling Filter Propagation

Filter propagation is disabled by default in _Routing Service_. You can enable filter propagation with the `<filter_propagation>` tag available under the _TopicRoute_ configuration (see Section 3.5.6) and _AutoTopicRoute_ configuration (see Section 3.5.8).

### 7.2 Filter Propagation Behavior

Without filter propagation, the only way to enforce writer-side filtering in a scenario involving one or more _Routing Services_ between the user _DataWriters_ and user _DataReaders_ is by statically configuring the content filter individually for each DDS _StreamReader_. This method has two main disadvantages:

---

\(^1\) The ability to perform writer-side filtering is subject to some restrictions. For the sake of this discussion, we will assume that the configuration of _DataReaders_, _DataWriters_, and _Routing Services_ is such that writer-side filtering is allowed.
Figure 7.1: Without propagation, user *DataWriters* send all the samples; filtering occurs on the last route's *StreamWriter*

Figure 7.2: With propagation, user *DataWriters* receive a composed filter that allows writer-side filtering, thus sending only the samples of interest to the *DataReaders*

### 7.2. Filter Propagation Behavior
Filter propagation can address the above issues by dynamically updating the StreamReaders filters. The composed filter associated with a StreamReader in a Route is built by aggregating the filter information associated with all DataReaders that match the Route’s StreamWriter, as shown in Figure 7.3.

The composed filter (CF) is the union of the matching DataReaders filters; it allows passing any sample that passes at least one of the DataReader filters.

\[ CF = F_1 \cup F_2 \ldots \cup F_N \]

For the SQL filter, the union operator is OR:

\[ CF_{SQL} = F_{SQL1} \cup F_{SQL2} \ldots \cup F_{SQLN} \]

Filter propagation occurs within a Route as follows: the Route output StreamWriter gathers the filter information coming from all of its matching DataReaders and provides the resulting composed filter to the Route input StreamReader, whose DataReader is responsible for sending this information to all of its matching DataWriters.

### 7.3 Filter Propagation Events

These events will cause a StreamReader’s filter to be updated and propagated:
• **Route StreamReader creation**: The initial filter is set to the *stop-band* filter, which is a special kind of filter that does not let any sample pass. This filter is propagated upon SR creation and it will remain unchanged until a matching *DataReader* to the *Route StreamWriter* is discovered.

• **Discovery of a matching DataReader in a DataReader**: The filter of the discovered *DataReader* will be aggregated to the existing *StreamReader*’s filter, which will be propagated after being updated. If the discovered *DataReader* does not have a filter (subscribes to all the samples) or it has a non-SQL filter, the *StreamReader*’s filter is set to the *all-pass* filter (a special filter that lets all sample pass). The all-pass filter will remain set until there are no matching *DataReaders* to the *Route StreamWriter* without a filter or with a non-SQL filter.

• **A matching DataReader changes its filter, either in the expression or in the parameters**: The *StreamReader*’s filter is updated to incorporate the latest changes and is propagated afterwards.

### 7.4 Restrictions

Filter propagation cannot be enabled when:

- Using *Routes* or *AutoRoutes*, since they are meant to work with other adapters different than the builtin DDS one.

- A transformation is present in the *TopicRoute*’s output.

- Using remote administration, if the *TopicRoute* was enabled and started with the functionality initially disabled.

- If the *StreamReader*’s content filter class is not the builtin SQL filter. Filter propagation is not currently supported with other filter classes.
Chapter 8

Topic Query Support

Routing Service is fully compatible with TopicQueries; you can enable this functionality in TopicRoutes and AutoTopicRoutes with two different query modes:

- **Dispatch mode**: The TopicRoute’s DataWriter configured with TRANSIENT_LOCAL durability will accept matching TopicQueries and dispatch them from its own sample cache.

- **Propagation mode**: TopicQueries are propagated from the user DataReaders to the user DataWriters. These DataWriters will be the final endpoints that dispatch the propagated TopicQueries.

Routing Service allows propagating TopicQueries from DataReaders to DataWriters acting as a proxy of TopicQueries. Routing Service supports TopicQuery proxy in either of the above modes. It is not possible to enable both modes within the same TopicRoute. However, you can create multiple TopicRoutes/AutoTopicRoutes with different TopicQuery proxy modes.

You can enable a TopicQuery proxy with the `<topic_query_proxy>` tag available under the TopicRoute configuration (see Section 3.5.6) and AutoTopicRoute configuration (see Section 3.5.8). For general concepts about TopicQueries, please see the RTI Connext DDS Core Libraries User’s Manual.

The following sections describe the Routing Service proxy modes. Figure 8.1 summarizes the symbols you will see in the figures that illustrate the modes’ behaviors.

### 8.1 Dispatch Mode

Dispatch mode refers to enabling TopicQuery dispatch in a TRANSIENT_LOCAL TopicRoute’s DataWriter. This is done by configuring its TopicQueryDispatchQosPolicy. It no different than enabling a TopicQuery for a DataWriter in a user application.

Figure 8.2 shows a simple scenario. A TopicQuery (TQ_n) issued by a user DataReader (DR_n) will be received by the TopicRoute’s StreamWriter. The StreamWriter will process the TopicQuery and dispatch it, providing the corresponding samples from the available history in the StreamWriter. As a result, the user DataReader will receive live samples (S_{Live}) and TopicQuery samples (S_{TQ}).

Dispatch mode can be useful when the user DataWriter on the publication side is part of an application with low-resources requirements, such as low power consumption and small memory.
Figure 8.1: Symbol Legend for Proxy Modes Figures

- $S_{Live}$: Live Sample
- $S_{TQn}$: Sample for TopicQuery 'n'
- SR: StreamReader
- SW: StreamWriter
- DR: User DataReader
- DW: User DataWriter
capacity. In this case, a Routing Service instance connected to the application can cache a set of data published by the user DataWriter and dispatch the TopicQueries issued by user DataReaders.

To enable TopicQuery proxy dispatch mode, use the following configuration tags within a TopicRoute/AutoTopicRoute configuration:

```xml
<topic_query_proxy>
  <mode>DISPATCH</mode>
</topic_query_proxy>
```

The above configuration will cause the Durability QoS setting for the TopicRoute’s output DataWriter to be TRANSIENT_LOCAL and will enable TopicQuery dispatch. If you want to configure advanced dispatch features, you can set other options in the TopicQueryDispatchQosPolicy within the corresponding DataWriter QoS tag.

### 8.2 Propagation Mode

Propagation mode refers to having Routing Service act as a proxy of TopicQueries. The TopicRoutes propagate the TopicQueries issued by the matching user DataReaders to the matching user DataWriters. Then the samples generated for both the TopicQuery and live stream are ‘propagated’ to the original user DataReaders. Figure 8.3 shows a simple scenario.

The TopicRoute propagates the TopicQuery requests from user DataReaders on the subscription side to the user DataWriters on the publication side. User DataWriters eventually dispatch the TopicQuery requests and generate samples for the TopicQuery stream. The samples for a specific TopicQuery are routed to the corresponding original user DataReader that issued such TopicQuery.

For a given TopicRoute, the propagation of TopicQuery requests and samples for both the TopicQuery and live stream occurs sequentially. The expected traffic pattern consists of TopicQuery

---

Figure 8.2: TopicRoute Enabling TopicQuery Proxy in Dispatch Mode
requests, TopicQuery samples, and live samples interleaved.

TopicQuery propagation is also compatible with filter propagation (see Section 7). You can enable both at the same time and expect live samples to be filtered accordingly, and TopicQuery samples to be unaffected by the filters.

To enable TopicQuery proxy dispatch mode, you can use the following configuration tags within a TopicRoute/AutoTopicRoute configuration:

```xml
<topic_query_proxy>
  <mode>PROPAGATION</mode>
</topic_query_proxy>
```

Note that the above configuration will cause the TopicRoute’s output DataWriter durability QoS setting to be VOLATILE.

### 8.3 Restrictions

TopicQuery proxy in PROPAGATION mode cannot be enabled when:

- Using Routes or AutoRoutes, since they are meant to work with other adapters different than the builtin DDS one.
- A transformation is present in the TopicRoute’s output.
- The TopicRoute has more than input or output.
- The TopicRoute has a custom processor.
Chapter 9

Traversing Wide Area Networks

Many systems today already rely on Connext DDS to distribute their information across a Local Area Network (LAN). However, more and more of these systems are being integrated in Wide Area Networks (WANs). With Routing Service, you can scale Connext DDS real-time publish/subscribe data-distribution beyond the current local networks and make it available throughout a WAN.

Out of the box, Routing Service only uses UDPv4 and Shared Memory transports to communicate with other Routing Services and Connext DDS applications. This configuration is appropriate for systems running within a single LAN. However, using UDPv4 introduces several problems when trying to communicate with Connext DDS applications running in different LANs:

- UDPv4 traffic is usually filtered out by the LAN firewalls for security reasons.
- Forwarded ports are usually TCP ports.
- Each LAN may run in its own private IP address space and use NAT (Network Address Translation) to communicate with other networks.

To overcome these issues, Routing Service is distributed with a TCP transport that is NAT friendly. The transport can be configured via XML using the PropertyQosPolicy of the Routing Services participants.

Figure 9.1 shows a typical scenario where two Routing Services are used to bridge two Connext DDS applications running in two different LANs.

9.1 TCP Configuration elements

The TCP transport distributed with Routing Service can be used to address multiple communication scenarios that range from simple communication within a single LAN to complex communication scenarios across LANs where NATs and firewalls may be involved.

9.1.1 TCP Transport Initial Peers

With the TCP transport, the addresses of the initial peers (NDDS_DISCOVERY_PEERS) that will be contacted during the discovery process have the following format:
Figure 9.1: WAN Communication Using TCP Transport

For WAN communication: tcpv4_wan://<IP address or hostname>:<port>
For LAN communication: tcpv4_lan://<IP address or hostname>:<port>
For WAN+TLS communication: tlsv4_wan://<IP address or hostname>:port
For LAN+TLS communication: tlsv4_lan://<IP address or hostname>:port

Example: Setting discovery peers for TCP wan/lan

```
setenv NDDS_DISCOVERY_PEERS tcpv4_wan://10.1.165:7400,tcpv4_wan://10.1.111:7400,
tcpv4_lan://192.168.1.1:7500
```

When the TCP transport is configured for LAN communication (with the `parent.classid` property), the IP address is the LAN address of the peer and the port is the server port used by the transport (the `server_bind_port` property).

When the TCP transport is configured for WAN communication (with the `parent.classid` property), the IP address is the WAN or public address of the peer and the port is the public port that is used to forward traffic to the server port in the TCP transport.

When TLS is enabled, the transport settings are similar to WAN and LAN over TCP. See Figure 9.2.  

9.1. TCP Configuration elements
9.1.2 TCP Transport Property

You can configure the TCP transport in Routing Service in the same manner as a Connext DDS application. Transports are configured at the DomainParticipant level by means of the PropertyQosPolicy. For details, see transport plugins in RTI Connext DDS Users Manual. For a list of available transport properties for TCP, see RTI TCP Transport configuration.

9.2 Support for External Hardware Load Balancers in TCP Transport Plugin

For two Connext DDS applications to communicate, the TCP Transport Plugin needs to establish 4-6 connections between the two communicating applications. The plugin uses these connections to exchange DDS data (discovery or user data) and TCP Transport Plugin control messages.

With the default configuration, the TCP Transport Plugin does not support external load balancers. This is because external load balancers do not forward the traffic to a unique TCP Transport Plugin server, but they divide the connections among multiple servers. Because of this behavior, when an application running a TCP Transport Plugin client tries to establish all the connections to an application running a TCP Transport Plugin server, the server may not receive all the required connections.

In order to support external load balancers, the TCP Transport Plugin provides a session-ID negotiation feature. When session-ID negotiation is enabled (by setting the negotiate_session_id property to true), the TCP Transport Plugin will perform the negotiation depicted in Figure 9.3.

During the session-ID negotiation, the TCP Transport Plugin exchanges three types of messages:

- **Session-ID Request**: This message is sent from the client to the server. The server must respond with a session-ID response.
• **Session-ID Response**: This message is sent from the server to the client as a response to a session-ID request. The client will store the session ID contained in this message.

• **Session-ID Indication**: This message is sent from the client to the server; it does not require a response from the server.

The negotiation consists of the following steps:

1. The TCP client sends a session-ID request with the session ID set to zero.
2. The TCP server sends back a session-ID response with the session ID set to zero.
3. The external load balancer modifies the session-ID response, setting the session ID with a value that is meaningful to the load balancer and identifies the session.
4. The TCP client receives the session-ID response and stores the received session ID.
5. For each new connection, the TCP client sends a session-ID indication containing the stored session ID. This will allow the load balancer to redirect to the same server all the connections with the same session ID.

Figure 9.4 depicts the TCP payload of a session-ID message. The payload consists of 48 bytes. In particular, your load balancer needs to read/modify the following two fields:

- **CTRLTYPE**: This field allows a load balancer to identify session-ID messages. Its value (two bytes) varies according to the session-ID message type: 0x0c05 for a request, 0xd05 for a response, or 0xc015 for an indication.
- **SESSION-ID**: This field consists of 16 bytes that the load balancer can freely modify according
to its requirements.

![Figure 9.4: TCP Payload for Session-ID Message](image)

To ensure all the TCP connections within the same session are directed to the same server, you must configure your load balancer to perform the two following actions:

1. Modify the SESSION-ID field in the `session-id response` with a value that identifies the session within the load balancer.

2. Make the load-balancing decision according to the value of the SESSION-ID field in the `session-ID indication`.

---

9.2. Support for External Hardware Load Balancers in TCP Transport Plugin 95
Chapter 10

Tutorials

This chapter describes several examples, all of which use RTI Shapes Demo to publish and subscribe to topics which are colored moving shapes.

In each example, you can start all the applications on the same computer or on different computers in your network. If you don’t have Shapes Demo installed already, you should download and install it from RTI’s Downloads page or the RTI Support Portal (the latter requires an account name and password). If you are not already familiar with how to start Shapes Demo and change its domain ID, please see the Shapes Demo User’s Manual for details.

Important Notes:

- Please review Section 1.1 to understand where to find the examples (referred to as <path to examples>).
- The following instructions include commands that you will enter in a command shell. These instructions use forward slashes in directory paths, such as bin/rtiroutingservice. If you are using a Windows platform, replace all forward slashes in such paths with backwards slashes, such as bin\rtiroutingservice.
- If you run Shapes Demo and Routing Service on different machines and these machines do not communicate over multicast, you will have to set the environment variable NDDS_DISCOVERY_PEERS to enable communication. For example, assume that you run Routing Service on Host 1 and Shapes Demo on Host 2 and Host 3. In this case, the environment variable would be set as follows:

  Host 1:

  ```bash
  set NDDS_DISCOVERY_PEERS=<host2>,<host3> (on Windows systems)
  export NDDS_DISCOVERY_PEERS=<host2>,<host3> (on UNIX-based systems)
  ```

  Host 2:

  ```bash
  set NDDS_DISCOVERY_PEERS=<host1>
  ```

  Host 3:
10.1 Starting Shapes Demo

You can start Shapes Demo from the Learn tab in RTI Launcher.

![RTI Connex Launch 6.0.0](image)

Or from a command shell:

```
<NDDSHOME>/bin/rtishapesdemo
```

NDDSHOME is described in Section 1.1.

10.2 Example: Routing All Data from One Domain to Another

This example uses the default configuration file\(^1\) for Routing Service, which routes all data published on domain 0 to subscribers on domain 1.

1. Start Shapes Demo. We’ll call this the Publishing Demo. It uses domain ID 0.

2. Start a second copy of Shapes Demo. We’ll call this the Subscribing Demo. Then:
   - Open its Configuration dialog (under Controls).

\(^1\) `<NDDSHOME>/resource/xml/RTI_ROUTING_SERVICE.xml`
• Press Stop.
• Change the domain ID to 1.
• Press Start.

3. In the Publishing Demo, publish some Squares, Circles, and Triangles.

4. In the Subscribing Demo, subscribe to Squares, Circles and Triangles.

Notice that the Subscribing Demo does not receive any shapes. Since we haven’t started Routing Service yet, data from domain 0 isn’t routed to domain 1.

5. Start Routing Service by entering the following in a command shell:

```bash
cd <NDDSHOME>
bin/rtiroutingservice -cfgName default
```

Now you should see all the shapes in the Subscribing Demo.

You should see that the Subscribing Demo stops receiving shapes.

Additionally, you can start Routing Service (Step 5) with the following parameters:

- **-verbosity 3**, to see messages from Routing Service including events that have triggered the creation of routes.
- **-domainIdBase X**, to use domains X and X+1 instead of 0 and 1 (in this case, you need to change the domain IDs used by Shapes Demo accordingly). This option adds X to the domain IDs in the configuration file.

**Note:** -domainIdBase only affects the domain IDs of DomainRoute participants; it does not affect the domain IDs of participants used for monitoring or administration.

### 10.3 Example: Changing Data to a Different Topic of Same Type

In this example, Routing Service receives samples of topic Square and republishes them as samples of topic Circle.

1. Start Shapes Demo. We’ll call this the Publishing Demo. It uses domain ID 0.

2. Start a second copy of Shapes Demo. We’ll call this the Subscribing Demo. Then:
   • Open its Configuration dialog (under Controls).
   • Press Stop.
   • Change the domain ID to 1.
   • Press Start.

3. In the Publishing Demo, publish some Squares, Circles, and Triangles.

4. Start Routing Service by entering the following in a command shell:
5. In the Subscribing Demo, subscribe to Squares, Circles and Triangles.

   Notice that the Subscribing Demo does not receive any shapes. Since we haven’t started Routing Service yet, data from domain 0 isn’t routed to domain 1.

7. Try writing your own topic route that republishes triangles on domain 0 to circles on domain 1. Create some Triangle publishers and a Circle subscriber in the respective Shapes Demo windows.

10.4 Example: Changing Some Values in Data

So far, we have learned how to route samples from one topic to another topic of the same data type. Now we will see how to change the value of some fields in the samples and republish them.

1. Start Shapes Demo. We’ll call this the Publishing Demo. It uses domain ID 0.

2. Start a second copy of Shapes Demo. We’ll call this the Subscribing Demo. Then:
   - Open its Configuration dialog (under Controls).
   - Press Stop.
   - Change the domain ID to 1.
   - Press Start.

3. In the Publishing Demo, publish some Squares, Circles, and Triangles.

4. Start Routing Service by entering the following in a command shell:

```
cd <NDDSHOME>
bin/rtiroutingservice
-cfgFile <path to examples>/routing_service/shapes/topic_bridge_w_transf1.xml
-cfgName example
```

5. In the Subscribing Demo, subscribe to Squares, Circles and Triangles.

   Notice that the (x,y) coordinates of the shapes are inverted form what appears in the Publishing Demo.

7. Try changing the transformation to assign the output \texttt{shapesize} to the input \texttt{x}.
10.5 Example: Transforming the Data’s Type and Topic with an Assignment Transformation

This example shows how to transform the data topic and type. We will use `rtiddsspy` to verify the result. `rtiddsspy` is a utility provided with Connext DDS; it monitors publications on any DDS domain.

1. Start Shapes Demo. We’ll call this the Publishing Demo. It uses domain ID 0.
2. In the Publishing Demo, publish some Squares, Circles, and Triangles.
3. Start Routing Service by entering the following in a command shell:

   ```
   cd <NDDSHOME>
   bin/rtiroutingservice
   -cfgFile <path to examples>/routing_service/shapes/topic_bridge_w_transf2.xml
   -cfgName example
   ```

4. We will use the `rtiddsspy` utility to verify the transformation of the data topic and type. Run these commands:

   ```
   cd <NDDSHOME>
   bin/rtiddsspy -domainId 0 -printSample
   bin/rtiddsspy -domainId 1 -printSample
   ```

   You will notice that the publishing samples received by `rtiddsspy` for domain 0 are of type ShapeType and topic Square. The subscribing samples received by `rtiddsspy` for domain 1 are of type Point and topic Position. Notice that the two data structures are different.

5. Stop Routing Service by pressing Ctrl-c.

10.6 Example: Transforming the Data with a Custom Transformation

Now we will use our own transformation between shapes. Routing Service allows you to install plug-ins that implement the Transformation API to create custom transformations. To build a custom transformation, you must have the Connext DDS libraries installed.

**Note:** This example assumes your working directory is `<path to examples>/routing_service/shapes/transformation/[make or windows]`. If your working directory is different, you will need to modify the configuration `topic_bridge_w_custom_transf.xml` to update the paths.

1. Compile the transformation in `<path to examples>/routing_service/shapes/transformation/[make or windows]`:
   - On UNIX-based systems:
     - Set the environment variable NDDSHOME (see Section 1.1). For details on how to set it, see the RTI Connext DDS Core Libraries Getting Started Guide.
Enter:

```
cd <path to examples>/routing_service/shapes/transformation/make
gmake -f Makefile.<architecture>
```

- On Windows systems:
  - Set the environment variable NDDSHOME (see Section 1.1). For details on how to set it, see the *RTI Connext DDS Core Libraries Getting Started Guide*.
  - Open the Visual Studio solution under `<path to examples>\routing_service\shapes\transformation\windows`.
  - Select the Release DLL build mode and build the solution.

2. Start *Shapes Demo*. We’ll call this the Publishing Demo. It uses domain ID 0.

3. In the Publishing Demo, publish some Squares.

4. Start *Routing Service* by entering the following in a command shell:

```
cd `<NDDSHOME>`
bin/rtiroutingservice
-cfgFile `<path to examples>/routing_service/shapes/topic_bridge_w_custom_...
-cfgName example
```

5. Start a second copy of *Shapes Demo*. We’ll call this the Subscribing Demo. Then:
   - Open its Configuration dialog (under Controls).
   - Press Stop.
   - Change the domain ID to 1.
   - Press Start.

6. In the Subscribing Demo, subscribe to Squares.
   Notice that squares on domain 1 have only two possible values for \(x\).

7. Stop *Routing Service* by pressing Ctrl-c.

8. Change the fixed ‘\(x\)’ values for the Squares in the configuration file and restart *Routing Service*.

10. Edit the source code (in shapestransf.c) to make the transformation multiply the value of the field by the given integer constant instead of assigning the constant.

```
Hint: Look for the function ShapesTransformationPlugin_createOutputSample(), called from ShapesTransformation_transform() and use DDS_DynamicData_get_long() before DDS_DynamicData_set_long().
```
11. Recompile the transformation (the new shared library will be copied automatically) and run Routing Service as before.

10.7 Example: Using Remote Administration

In this example, we will configure Routing Service remotely. We won’t see data being routed until we remotely enable an AutoTopicRoute after the application is started. Then we will change a QoS value and see that it takes effect on the fly.

1. Start Shapes Demo. We’ll call this the Publishing Demo. It uses domain ID 0.

2. In the Publishing Demo, publish some Squares, Circles and Triangles.

3. Start Routing Service by entering the following in a command shell:

   ```
   cd <NDDSHOME>
   bin/rtiroutingservice
   -cfgFile <path to examples>/routing_service/shapes/administration.xml
   -cfgName example -appName MyRoutingService
   ```

4. Start a second copy of Shapes Demo. We’ll call this the Subscribing Demo. Then:
   - Open its Configuration dialog (under Controls).
   - Press Stop.
   - Change the domain ID to 1.
   - Press Start.

5. In the Subscribing Demo, subscribe to Squares, Circles and Triangles.

   Notice that no data is routed to domain 1.

6. On a different or the same machine, start the Routing Service remote shell:

   ```
   cd <NDDSHOME>
   bin/rtirssh -domainId 0
   ```

   **Note:** We use domain 0 in the shell because Routing Service is configured in administration.xml to receive remote commands on that domain. You could have started Routing Service with the -remoteAdministrationDomainId command-line option and then used domain X for the shell.

7. In the shell, enter the following command:

   ```
   enable MyRoutingService RemoteConfigExample::Session::Shapes
   ```

   Notice that the shapes are now received on domain 1. The above command consists of two parts: the name of the Routing Service, which you gave when you launched the application with the option -appName, and the name of the entity you wanted
to enable. That name is formed by appending its parent entities’ names starting from the domain route as defined in the configuration file administration.xml.

You could have run Routing Service without -appName. Then the name would be the one provided with -cfgName (“example”). You could also have used -identifyExecution to generate the name based on the host and application ID. In this case, you would have used this automatic name in the shell.

8. Examine the file <path to examples>/routing_service/shapes/time_filter_qos.xml on the Routing Service machine. It contains an XML snippet that defines a QoS value for an auto topic route’s DataReader. Execute the following command in the shell:

```
update MyRoutingService RemoteConfigExample::Session::Shapes \
<path to examples>/routing_service/shapes/time_filter_qos.xml
```

Notice that the receiving application only gets shapes every 2 seconds. The AutoTopicRoute has been configured to read (and forward) samples with a minimum separation of 2 seconds.

Routing Service can be configured remotely using files located on the remote machine or the shell machine. In the next step you will edit the configuration files on both machines. Then you will see how to specify which of the two configuration files you want to use. If you are running the shell and |RS| on the same machine, skip steps 9 and 10.

9. Edit the XML configuration files on both machines:

- In <path to examples>/routing_service/shapes/time_filter_qos.xml on the service machine, change the minimum separation to 0 seconds.
- In <path to examples>/routing_service/shapes/time_filter_qos.xml on the shell machine, change the minimum separation to 5 seconds.

10. Run the following commands in the shell:

- Enter the following command. Notice the use of remote at the end—this means you want to use the XML file on the service machine (the remote machine, which is the default if nothing is specified).

```
update MyRoutingService RemoteConfigExample::Session::Shapes \
<path to examples>/routing_service/shapes/time_filter_qos.xml remote
```

Note: The path to the XML file in this example is relative to the working directory from which you run Routing Service.

Since no time filter applies, the shapes are received as they are published.

- Enter the following command. This time use local at the end—this means you want to use the XML file on the shell machine (the local machine).
10.7. Example: Using Remote Administration

```plaintext
update MyRoutingService RemoteConfigExample::Session::Shapes 
   <path to examples>/routing_service/shapes/time_filter_qos.xml local
```

**Note:** The path to the XML file in this example is relative to the working directory from which you run the *Routing Service* shell.

You will see that now the shapes are only received every 5 seconds.

- Enter the following command. Once again, we use `remote` at the end to switch back to the XML file on the remote machine.

```plaintext
update MyRoutingService RemoteConfigExample::Session::Shapes 
   <path to examples>/routing_service/shapes/time_filter_qos.xml remote
```

Shapes are once again received as they are published.

11. Disable the *AutoTopicRoute* again by entering:

```plaintext
disable MyRoutingService RemoteConfigExample::Session::Shapes
```

The shapes are no longer received on Domain 1.

**Note:** At this point, you could still update the *AutoTopicRoute*’s configuration. You could also change immutable QoS values, since the *DataWriter* and *DataReader* haven’t been created yet. These changes would take effect the next time you called `enable`.

12. Run these commands in the shell and see what happens after each one:

```plaintext
enable MyRoutingService RemoteConfigExample::Session::SquaresToCircles
disable MyRoutingService RemoteConfigExample::Session::SquaresToCircles
enable MyRoutingService RemoteConfigExample::Session::SquaresToTriangles
```

These commands change the output topic that is published after receiving the input Square topic. As you can see, you can use the shell to switch *TopicRoutes* after *Routing Service* has been started.

13. Perform a remote shutdown of the service. Run the following command:

```plaintext
shutdown MyRoutingService
```

You should receive a reply indicating that the shutdown sequence has been initiated. Verify in the terminal in which *Routing Service* was running that the process is exiting or has already exited.

14. Stop the shell by running this command in the shell:

```plaintext
exit
```
10.8 Example: Monitoring

You can publish status information with Routing Service. The monitoring configuration is quite flexible and allows you to select the entities that you want to monitor and how often they should publish their status.

1. Start Shapes Demo. We’ll call this the Publishing Demo. It uses domain ID 0.
2. In the Publishing Demo, publish two Squares, two Circles and two Triangles.
3. Start a second copy of Shapes Demo. We’ll call this the Subscribing Demo. Then:
   - Open its Configuration dialog (under Controls).
   - Press Stop.
   - Change the domain ID to 1.
   - Press Start.
4. In the Subscribing Demo, subscribe to Squares, Circles and Triangles.
   At this point you will not see any shapes moving in the Subscribing Demo. It isn’t receiving shapes from the Publishing Demo because they use different domain IDs.
5. On a different or the same machine, start the Routing Service remote shell:

```
cd <NDDSHOME>
bin/rtirssh -domainId 0
```

**Note:** We use domain 0 in the shell because Routing Service is configured in administration.xml to receive remote commands on that domain. You could have started Routing Service with the **-remoteAdministrationDomainId** command-line option and then used domain X for the shell.

6. Start Routing Service by entering the following in a command shell:

```
cd <NDDSHOME>
bin/rtiroutingservice
   -cfgFile <path to examples>/routing_service/shapes/monitoring.xml
   -cfgName example -appName MyRoutingService
```

This configuration file routes Squares and Circles using two different TopicRoutes.
7. Now you can subscribe to the monitoring topics (see Section 5). You can do it in your own application, or by using RTI Admin Console or rtiddsspy. Enter the following in a terminal:

```
cd <NDDSHOME>
bin/rtiddsspy -domainId 2 -printSample
```

**Note:** We use domain 2 because Routing Service is configured in monitoring.xml to publish status information on that domain. You could have started Routing Ser-
vice with the \texttt{-remoteMonitoringDomainId X} command-line option and then used domain X for \texttt{rtiddsspy}.

8. Depending on the publication period of the entity in the XML file we used, you will receive status samples at different rates. In the output from \texttt{rtiddsspy}, check the statistics about the two topic routes we are using.

We will focus on the input samples per second. The number of samples per second in our case is 32. That value depends on the publication rate of \textit{Shapes Demo} configurable with the option \texttt{-pubInterval <milliseconds between writes>}.

9. Create two additional Square publishers in the Publishing Demo (domain 0).

10. Check \texttt{rtiddsspy} again for new status information.

    In the \textit{TopicRoute} for Squares, we are receiving double the amount of data.

11. Look at the status of the \textit{DataReader} in the output from \texttt{rtiddsspy}.

    It contains an aggregation of the two contained \textit{TopicRoutes}, giving us a mean of nearly 48 samples per second.

12. We can update the monitoring configuration at run time using the remote administration feature. In the configuration file, we enabled remote administration on domain 0.

    On a different or the same machine, start the \textit{Routing Service} remote shell:

    \begin{verbatim}
    cd <NDDSHOME>
    bin/rtirssh -domainId 0
    \end{verbatim}

13. We are receiving the status of the \textit{TopicRoute} Circles every five seconds. To receive it more often, use the following command:

    \begin{verbatim}
    update MyRoutingService DomainRoute::Session::Circles \ 
    topic_route.entity_monitoring.status_publication_period.sec=2
    \end{verbatim}

14. In some cases, you might want to know only about one specific \textit{TopicRoute}. If you only want to know about the topic route Circles but not Squares, you can disable monitoring for Squares:

    \begin{verbatim}
    update MyRoutingService DomainRoute::Session::Squares \ 
    topic_route.entity_monitoring.enabled=false
    \end{verbatim}

15. To enable it again, enter:

    \begin{verbatim}
    update MyRoutingService DomainRoute::Session::Squares \ 
    topic_route.entity_monitoring.enabled=true
    \end{verbatim}

16. If you are no longer interested in monitoring this service, you can completely disable it with the following command:

    \begin{verbatim}
    update MyRoutingService routing_service.monitoring.enabled=false
    \end{verbatim}
Now you won’t receive any more status samples.

17. You can enable it again any time by entering:

```
update MyRoutingService routing_service.monitoring.enabled=true
```

18. Stop `rtiddsspy` by pressing `Ctrl-c`.

19. Stop the shell:

```
exit
```

20. Stop Routing Service by pressing `Ctrl-c`.

### 10.9 Example: Using the TCP Transport

This example shows how to use Routing Service to bridge data between different LANs over TCP. Routing Service will act as the gateway in a LAN with which other Connext DDS applications can communicate to send or receive data. Section 9 has more information about scenarios and detailed configuration parameters.

You will run two copies of Routing Service. One copy will run on a machine that is behind a firewall/network router with a public IP (First Peer); the other will run on a machine in another LAN (Second Peer).

- On the First Peer (behind a firewall/router with a public IP):
  1. In the First Peer’s network, configure the firewall to forward the TCP ports used by Routing Service.

     In this example, we will use port 7400. You do not need to configure your firewall for every single Connext DDS application in your LAN; doing it just once for Routing Service will allow other applications to communicate through the firewall.

  2. Include the Second Peer’s public IP address and port in the `NDDS_DISCOVERY_PEERS` environment variable.

     For example, on a UNIX-based system:

     ```
     export NDDS_DISCOVERY_PEERS=tcpv4_wan://<server's public IP address>:\n$<port>
     ```

     On a Windows system:

     ```
     set NDDS_DISCOVERY_PEERS=tcpv4_wan://<server’s public IP address>:\n$<port>
     ```

     When you configure `NDDS_DISCOVERY_PEERS`, make sure to use a transport class prefix (tcpv4_wan, udpv4, shmem) for each entry. See discovery peer configuration for details.

  3. Set the public IP address and port in the configuration file:

     - Open the file `<path to examples>/routing_service/shapes/tcp_transport.xml`. 

10.9. Example: Using the TCP Transport
– The file contains several configurations. Find the configuration with name “TCP_1”. Then find the “public_address” property (<name>dds.transport.TCPv4.tcp1.public_address</name>) within that configuration.

– Set the local public IP address and port. For example, to set the address to 10.10.1.150 and port 7400:

```xml
<element>
  <name>dds.transport.TCPv4.tcp1.public_address</name>
  <value>10.10.1.150:7400</value>
</element>
```

– Save and close the file.

4. Start Routing Service by entering the following in a command shell:

```bash
cd <NDDSHOME>
bin/rtiroutingservice
-cfgFile <path to examples>/routing_service/shapes/tcp_transport.xml
-cfgName TCP_1
```

5. On any computer in this LAN, start Shapes Demo and publish some shapes on domain 0.

- On the Second Peer (a machine in any other LAN):
  1. Include the First Peer’s public IP address and port in the NDDS_DISCOVERY_PEERS environment variable the same way you did before.
  2. Set the public IP address and port in the configuration file:
     - Open the file <path to examples>/routing_service/shapes/tcp_transport.xml.
     - The file contains several configurations. Find the configuration with name “TCP_2”. Then find the “public_address” property (<name>dds.transport.TCPv4.tcp1.public_address</name>) within that configuration.
     - Set the local public IP address and port. For example, to set the address to 10.10.1.10 and port 7400:

```xml
<element>
  <name>dds.transport.TCPv4.tcp1.public_address</name>
  <value>10.10.1.10:7400</value>
</element>
```

– Save and close the file.

3. Start Routing Service by entering the following in a command shell:

```bash
cd <NDDSHOME>
bin/rtiroutingservice
-cfgFile <path to examples>/routing_service/shapes/tcp_transport.xml
-cfgName TCP_2
```
4. On any computer in this LAN, start *Shapes Demo* and create subscribers on domain 2. Do not use an already running instance of *Shapes Demo*—you need a new one that uses a different domain ID. You should receive what is being published in the server’s LAN.

- **Notes:**
  
  - **Running Shapes Demo on a Different Computer**
    
    If the computer running *Shapes Demo* is different than the computer running the client *Routing Service*, add the address of the client (IP address or host name) to the *Shapes Demo* discovery peers before starting *Shapes Demo*. To do so, set the `NDDS_DISCOVERY_PEERS` environment variable.
  
  - **Using Two Computers in the Same LAN**
    
    If both machines are in the same LAN, run both *Routing Service* with the configuration file `tcp_transport_lan.xml` and use `tcpv4_lan://` as the peer prefix in the environment variable `NDDS_DISCOVERY_PEERS`. At least one of the peer descriptors must contain the port number.
    
    For example, suppose the first peer is 192.168.1.3, the second peer is 192.168.1.4, and you want to use port 7400. On the first peer set `NDDS_DISCOVERY_PEERS` to `tcpv4_lan://192.168.1.4:7400` and on the second peer set it to `tcpv4_lan://192.168.1.3:7400`. You don’t need to specify an IP address in the configuration file.
  
  - **Running the Example on One Computer**
    
    To run the example on the same machine, open the file `<path to examples>/routing_service/ shapes/tcp_transport_lan.xml` and change the property `dds.transport.TCPv4.tcp1.server_bind_port` within `TCP_1` to 7401. Run both *Routing Service* with the modified `tcp_transport_lan.xml` configuration file and use `tcpv4_lan://` as the peer prefix in the environment variable `NDDS_DISCOVERY PEERS`. You will also need to specify port 7401 in the `tcpv4_lan` peer in the `NDDS_DISCOVERY_PEERS` environment variable of the *Routing Service* in the Second Peer to reflect this port change in the configuration file.
  
  - **Using a Secure Connection over WAN**
    
    To run the example using a secure connection between the two *Routing Service* instances, use the configuration file `tcp_transport_tls.xml`. You will also need to set the peer prefix to `tlsv4_wan://` in the `NDDS_DISCOVERY_PEERS` environment variable. The `tcp_transport_tls.xml` file is based on `tcp_transport.xml` and uses a WAN configuration to establish communication. Because TLS is enabled, you must ensure that the *RTI TLS Support* and OpenSSL libraries are present in your library path before starting the applications.

  **Note:** To run this example, you need the *RTI TCP Transport*, which is shipped with *RTI Connext DDS*. Additionally, you will need to install the optional packages *RTI TLS support* and OpenSSL.

  - **Using a Secure Connection over LAN**

---

10.9. Example: Using the TCP Transport 110
Similar to the previous point, but instead you will use the file `tcp_transport_tls_lan.xml` and prefix `tlsv4_lan://`.

### 10.10 Example: Using a File Adapter

The previous examples showed how to use *Routing Service* with *Connext DDS*. In this one you will learn how to use *RTI Routing Service Adapter SDK* to create an adapter that writes and reads data from files. *Routing Service* allows you to bridge data from different data domains with a pluggable adapter interface.

To learn how to implement your own adapter, you can follow this example and the next examples and inspect the code that is distributed with these adapters. The file adapter can read data from files with a specific format and provide it to *Routing Service*, or receive data from *Routing Service* and write it into files.

In this example, we will first write topic data (a colored square and circle) into a file and then use that file to write it back into *Connext DDS*, allowing us to modify the data with a text editor.

- Compile the Adapter in `adapters/file/src`:
  - Set `NDDSHOME` to point to your *RTI Connext DDS* installation.
  - On UNIX-based systems, enter:
    ```bash
    cd <path to examples>/routing_service/adapters/file/make
gmake -f Makefile.<architecture>
    ```
    The adapter shared library, `libfileadapter.so`, will be copied to `<path to examples>/routing_service/adapters/file`.
  - On Windows systems:
Open the Visual Studio solution under <path to examples>/routing_service/adapters/file/windows. For example, if you are using Visual Studio 2013, open fileadapter-vs2013.sln.

* Build the solution. The adapter shared library, fileadapter.dll, will be copied to <path to examples>/routing_service/adapters/file.

From Connext DDS to files:
1. Run Shapes Demo and Routing Service as in the previous examples:
   - Start Shapes Demo on domain 0 (the default domain).
   - Start Routing Service by entering the following in a command shell:

   ```
   cd <NDDSHOME>
   bin/rtiroutingservice
   -cfgFile <path to examples>/routing_service/shapes/file_bridge.xml \
   -cfgName dds_to_file
   ```

2. In Shapes Demo, publish some Squares.

3. Wait a few seconds and then stop Routing Service by pressing Ctrl-c.

4. A file called MySquare.txt should have been created in the current directory. Open it with a text editor of your choice. It should contain several lines, each consisting of a list of <field>=<value> elements. Each line represents a sample (Square) published by Shapes Demo and written by Routing Service and the file adapter.

   On UNIX-based systems, you can see how new samples are appended to the file by running the following command while Routing Service runs:

   ```
   tail - f MySquare.txt
   ```

From a file to Connext DDS:
1. In Shapes Demo, delete the Square publisher and create a Square subscriber.

2. Start Routing Service by entering the following in a command shell:

   ```
   cd <NDDSHOME>
   bin/rtiroutingservice
   -cfgFile <path to examples>/routing_service/shapes/file_bridge.xml \
   -cfgName file_to_dds
   ```

You should see squares being received by Shapes Demo. These samples come from what we recorded before.

You might have noticed that the rate at which the shape moves is much slower. This is the rate at which the file adapter is providing data to Routing Service. To change this rate, open file_bridge.xml and look for `<route name="square_file">` within `<routing service name="file_to_dds">`. In the `<property>` tag, change the property ReadPeriod from 1000 (milliseconds) to 100.
3. Stop *Routing Service* and restart it as described in previous steps. The squares should be received and displayed about ten times faster.

4. Other properties that you can configure in the file adapter are: In the input, FileName, MaxSampleSize, Loop and SamplesPerRead; in the output, FileName.

5. You can also edit the text file and publish the new data. Open *MySquare.txt* and replace all the occurrences of “shapesize=30” with “shapesize=100”.

6. Stop *Routing Service* and restart it as described in previous steps. The squares will have the same position and color, but they will be bigger now.

- Customize the File Adapter:

  In the example, the file adapters use a specific format, which you already saw in the file *MySquare.txt*. Now try adapting the example to your own format.

  The code that reads/writes from the file is in *adapters/file/src/LineConversion.c*.

  1. Edit the function `RTI_RoutingServiceFileAdapter_read_sample` to implement how file data maps into a sample.

  2. Edit the function `RTI_RoutingServiceFileAdapter_write_sample` to implement how a sample is written to a file.

### 10.11 Example: Using a Shapes Processor

This example shows how to implement a custom *Processor* plug-in, build it into a shared library and load it with *Routing Service*.

This example illustrates the realization of two common enterprise patterns: aggregation and splitting. There is a single plug-in implementation, *ShapesProcessor* that is a factory of two types of *Processor*, one for each pattern implementation:

- *ShapesAggregator*: *Processor* implementation that performs the aggregation of two *ShapeType* objects into a single *ShapeType* object.

- *ShapesSplitter*: *Processor* implementation that performs the separation of a single *ShapeType* object into two *ShapeType* objects.

In the example, these processors are instantiated as part of a *TopicRoute*, in which all its inputs and outputs represent instantiations of the *Connext DDS Adapter StreamReader* and *StreamWriter*, respectively.

You can find the full example in the RTI Community Examples Repository.
Chapter 11

Common Infrastructure

11.1 Application Resource Model

RTI services are described through a hierarchical application resource model. In this model, an application is composed of a set of Resources, each representing a particular component within the application. Resources have a parent-child relationship. Figure 11.1 shows a general view of this concept.

![Diagram showing the application made up of related Resources](image)

Figure 11.1: Application modeled as a set of related Resources

Each application specifies its resource model by indicating the available resources and their relationship. A Resource is determined by its class and a concrete object instance. It can belong to one of the following categories:

- **Simple**—Represents a single object.
- **Collection**—Represents a set of objects of the same class.

A Resource may be composed of one or more Resources. In this relationship, the *parent* Resource is composed of one or more *child* Resources.

### 11.1.1 Example: Simple Resource Model of a Connext DDS Application

Figure 11.2 depicts a UML class diagram to provide a generic resource model for *Connext DDS* applications.

![UML class diagram](image)

Figure 11.2: Connext DDS application resource model

In this diagram, the composition relationship is used to denote the parents and children in the hierarchy. The direct relationship denotes a dependency between resources that is not parent-child.

**Resource Identifiers**

A resource identifier is a string of characters that uniquely address a concrete resource object within an application. It is expressed as a hierarchical sequence of identifiers separated by `/`, including all the parent resources and the target resource itself:

```
/resource_id1/resource_id2.../resource_id_N
```

where each individual identifier references a concrete resource object *by its name*. The object name is either:

1. Fixed and specified by the resource model of the parent Resource class.
2. Given by the user of the application. This is the case where the parent resource is a collection in which the user can insert objects, providing a name for each of them.

The individual identifier can refer to one of the two kinds of resources, simple and collection resources. For example:
If the identifier refers to a collection resource, the following child identifier must refer to a simple resource. Both simple and collection resources can be parents (or children). In the previous example, resource_id1 is a simple resource child of collection_id1; it is also the parent of resource_id2.

The hierarchy of identifiers is known as the **full resource identifier path**, where each resource on the left represents a parent resource. The **full resource identifier path** is composed of collection and simple resources. Each child resource identifier is known as the **relative resource** to the parent.

The resource identifier format follows these conventions:

- The first character is `/`, which represents the root resource and parent of all the available resources across the applications.
- A collection identifier is defined in lower **snake_case**, and it is always specified by the resource class.
- A simple resource identifier is defined in **camelCase** (lower and upper) and may be specified by both the resource class or the user.

11.1.2 Example: Resource Identifiers of a Generic Connext DDS Application

Consider the *Connext DDS* application resource model in Section 11.1.1. The following resource identifier addresses a concrete *DomainParticipant* named “MyParticipant” in a given application:

```
/domain_participants/MyParticipant
```

In this case, “domain_participants” is the identifier of a collection resource that represents a set of *DomainParticipants* in the application and its value is fixed and specified by the application. In contrast, “MyParticipant” is the identifier of a simple resource that represents a particular *DomainParticipant* and its value is given by the user of the application at *DomainParticipant* creation time.

The following resource identifier addresses the implicit *Publisher* of a concrete *DomainParticipant* in a given application:

```
/domain_participants/MyParticipant/implicit_publisher
```

where “implicit_publisher” is the identifier of a simple resource that represents the always-present implicit *Publisher* and its value is fixed and specified by the *DomainParticipant* resource class.

11.2 Remote Administration Platform

This section describes details of the *RTI Remote Administration Platform*, which represents the foundation of the remote access capabilities available in *RTI Routing Service*, *RTI Recording Service*, and *RTI Queuing Service*. The *RTI Remote Administration Platform* provides a common infrastructure that unifies and consolidates the remote interface to all RTI services.
Note: Remote administration of RTI services requires an understanding of the application resource model. We recommend that you read Application Resource Model (Section 11.1) before continuing with this section.

The RTI Remote Administration Platform addresses two areas:

- **Resource Interface**: How to perform operations on a set of resource objects that are available as part of the public interface of the remote service.

- **Communication**: How the remote service receives and sends information.

The combination of these two areas provides the general view of the RTI Remote Administration Platform, as shown in Figure 11.3. The RTI Remote Administration Platform is defined as a request/reply architecture. In this architecture, the service is modeled as a set of resources upon which the requester client can perform operations. Resources represent objects that have both state and behavior.

![Figure 11.3: General View of the RTI Remote Administration Platform Architecture](image)

Clients issue requests indicating the desired operation and receive replies from the service with the result of the requests. If multiple clients issue multiple requests to one or more services, the client will receive only replies to its own requests.

### 11.2.1 Remote Interface

Services offer their available functionality through their set of resources. The RTI Remote Administration Platform defines a Representational State Transfer (REST)-like interface to address service resources and perform operations on them. A resource operation is determined by a REST request and the associated result by a REST reply.

11.2. Remote Administration Platform
Table 11.1: REST Interface

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REST Request</td>
<td>[method] + [resource_identifier] + [body]</td>
</tr>
<tr>
<td></td>
<td>• method: Specifies the action to be performed on a service resource. There is only a small subset of methods, known as standard methods (see Section 11.2.1).</td>
</tr>
<tr>
<td></td>
<td>• resource_identifier: Addresses a concrete service resource. Each concrete service has its own set of resources (see Section 11.1.1).</td>
</tr>
<tr>
<td></td>
<td>• body: Optional request data that contains necessary information to complete the operation.</td>
</tr>
<tr>
<td>REST Reply</td>
<td>[return code] + [body]</td>
</tr>
<tr>
<td></td>
<td>• return code: Integer indicating the result of the operation.</td>
</tr>
<tr>
<td></td>
<td>• body: Optional reply data that contains information associated with the processing of the request.</td>
</tr>
</tbody>
</table>

**Standard Methods**

The *RTI Remote Administration Platform* defines the methods listed in Table 11.2.

Table 11.2: Standard Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>URI</th>
<th>Request Body</th>
<th>Reply Body</th>
</tr>
</thead>
<tbody>
<tr>
<td>CREATE</td>
<td>Parent collection resource identifier</td>
<td>Resource representation</td>
<td>N/A</td>
</tr>
<tr>
<td>GET</td>
<td>Resource identifier</td>
<td>N/A</td>
<td>Resource representation</td>
</tr>
<tr>
<td>UPDATE</td>
<td>Resource identifier</td>
<td>Resource representation</td>
<td>N/A</td>
</tr>
<tr>
<td>DELETE</td>
<td>Resource identifier</td>
<td>Undefined</td>
<td>N/A</td>
</tr>
</tbody>
</table>

**Custom Methods**

There are certain cases in which an operation on a service resource cannot be mapped intuitively to a standard method and resource identifier. *Custom methods* address this limitation.

A custom method can be specified as part of the resource identifier, after the resource path, separated by a :.

```
UPDATE + [resource_identifier] : [custom_verb]
```

It is up to each service implementation to define which custom methods are available and on what
resources they apply. Custom methods follow these conventions:

- They are invoked through the `UPDATE` standard method.
- They are named using lower snake_case.
- They may use the request body and reply body if necessary.

**Example: Database Rollover**

This example shows the REST request to perform a file rollover operation on a file-based database:

```
UPDATE /databases/MyDatabase:rollover
```

### 11.2.2 Communication

The information exchange between client and server is based on the DDS request-reply pattern, as shown in Figure 11.4. The client maps to a *Requester*, whereas the server maps to a *Replier*.

![Communication Diagram](attachment:communication_diagram.png)

Figure 11.4: Communication in *RTI Remote Administration Platform* is Based on DDS Request-Reply

The communication is performed over a single request-reply channel, composed of two topics:

- **Command Request Topic**: Topic through which the client sends the requests to the server.
- **Command Reply Topic**: Topic through which the server sends the replies to the received requests.

The definition of these topics is shown in Table 11.3:
Table 11.3: Remote Administration Topics

<table>
<thead>
<tr>
<th>Topic</th>
<th>Name</th>
<th>Top-level Type Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>CommandRequestTopic</td>
<td>rti/service/administration/command_request</td>
<td>rti::service::admin::CommandRequest</td>
</tr>
<tr>
<td>CommandReplyTopic</td>
<td>rti/service/administration/command_reply</td>
<td>rti::service::admin::CommandReply</td>
</tr>
</tbody>
</table>

The definition for each Topic type is described below.

Listing 11.1: CommandRequest Type

```cpp
@appendable
struct CommandRequest {
    @key int32 instance_id;
    @optional string<BOUNDED_STRING_LENGTH_MAX> application_name;
    CommandActionKind action;
    ResourceIdentifier resource_identifier;
    StringBody string_body;
    OctetBody octet_body;
};
```

Table 11.4: CommandRequest

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance_id</td>
<td>Associates a request with a given instance in the CommandRequestTopic. This can be used if your requester application model wants to leverage outstanding requests. In general, this member is always set to zero, so all requests belong to the same CommandRequestTopic instance.</td>
</tr>
<tr>
<td>application_name</td>
<td>Optional member that indicates the target service instance where the request is sent. If NULL, the request will be sent to all services.</td>
</tr>
<tr>
<td>action</td>
<td>Indicates the resource operation.</td>
</tr>
<tr>
<td>resource_identifier</td>
<td>Addresses a service resource.</td>
</tr>
<tr>
<td>string_body</td>
<td>Contains content represented as a string.</td>
</tr>
<tr>
<td>octet_body</td>
<td>Contains content represented as binary.</td>
</tr>
</tbody>
</table>
Listing 11.2: CommandReply Type

```c
@appendable
struct CommandReply {
    CommandReplyRetcode retcode;
    int32 native_retcode;
    StringBody string_body;
    OctetBody octet_body;
};
```

Table 11.5: CommandReply

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>retcode</td>
<td>Indicates the result of the operation.</td>
</tr>
<tr>
<td>native_retcode</td>
<td>Provides extra information about the result of the operation.</td>
</tr>
<tr>
<td>string_body</td>
<td>Return value of the operation, represented as a string.</td>
</tr>
<tr>
<td>octet_body</td>
<td>Return value of the operation, represented as binary.</td>
</tr>
</tbody>
</table>

The type definitions for both the `CommandRequestTopic` and `CommandReplyTopic` are in the file `[NDDSHOME]/resource/idl/ServiceAdmin.idl`.

The definition of the request and reply topics is independent of any specific service implementation. In fact, the topic names are fixed, unique, and shared across all services that rely on the `RTI Remote Administration Platform`. Clients can target specific services through two mechanisms:

- Specifying a concrete service instance by providing its *application name*. The application name is a service attribute and can be set at service creation time.
- Specifying the configuration name loaded by the target services. The target service configuration shall be present in the service resource part of the `resource_identifier`.

**Reply Sequence**

Usually a request is expected to generate a single reply. Sometimes, however, a request may trigger the *generation of multiple replies*, all associated with the same request.

The `RTI Remote Administration Platform` communication architecture allows services to respond to certain requests with a *reply sequence*. All the samples in a reply sequence use the metadata `SampleFlagBits` to indicate whether it belongs to a reply sequence and whether there are more replies pending.

The `SampleFlagBits` may contain different flags that indicate the status of the reply procedure. For a given reply sequence, the associated sample flags for each reply may contain:

- `SEQUENTIAL_REPLY`: If present, this indicates that the sample is the first reply of a reply sequence and there are more on the way.
- `FINAL_REPLY`: If present, this indicates that the sample is the last one belonging to a reply sequence. This flag is valid only if the `SEQUENTIAL_REPLY` is also set.
For more on SampleFlagBits, see documentation on the DDS_SampleInfo structure in the Connext DDS API Reference HTML documentation.

Example: Accessing from Connext DDS Application

This example shows a Modern C++ snippet on how to use Connext DDS Request-Reply to disable a Routing Service instance.

```cpp
using namespace rti::request;
using namespace dds::core;
using namespace RTI::Service;
using namespace RTI::Service::Admin;

const unsigned int WAIT_TIMEOUT_SEC_MAX = 10;
const unsigned int ADMIN_DOMAIN_ID = 55;

int main(int, char *[]) {
    try {
        dds::domain::DomainParticipant participant(ADMIN_DOMAIN_ID);

        // create requester params
        rti::request::RequesterParams requester_params(participant);
        requester_params.request_topic_name(COMMAND_REQUEST_TOPIC_NAME);
        requester_params.reply_topic_name(COMMAND_REPLY_TOPIC_NAME);

        // Wait for Routing Service Discovery
        dds::core::status::PublicationMatchedStatus matched_status;
        unsigned int wait_count = 0;
        std::cout << "Waiting for a matching replier..." << std::endl;
        int wait_count = 0;
        while (matched_status.current_count() < 1
            && wait_count < WAIT_TIMEOUT_SEC_MAX) {
            matched_status = requester.request_datawriter().publication_matched_status();
            wait_count++;
            rti::util::sleep(Duration(1));
        }

        if (matched_status.current_count() < 1) {
            throw dds::core::Error("No matching replier found.");
        }

        /* * Setup command */
        CommandRequest request;
        request.action(CommandActionKind::RTI_SERVICE_COMMAND_ACTION_UPDATE);
        request.resource_identifier("/routing_services/MyRouter/state");
        dds::topic::topic_type_support<EntityState>::to_cdr_buffer(
            static_cast<std::vector<char> &>(request.octet_body()),
            EntityState(RTI_SERVICE_DISABLED_ENTITY_STATE));
    }
} // end main
```

(continues on next page)
11.2.3 Common Operations

The set of services that use the *RTI Remote Administration Platform* to implement remote administration also share a base remote interface that consolidates and unifies the semantics and behavior of certain common operations.

Services containing resources that implement the common operations conform to the base remote interface, making sure that signatures, semantics, behavior, and conditions are respected.

The following sections describe each of these common operations.

Create Resource

CREATE [resource_identifier]

Creates a resource object from its configuration in XML representation.

This operation creates a resource object and its contained entities. The created object becomes a child of the parent specified in the *resource_identifier*.

After successful creation, the resource object is fully addressable for additional remote access, and the associated object configuration is inserted into the currently loaded full XML configuration.

Request body

- **string_body**: XML representation of the resource object provided as `file://` or `str://`.
- Example `str://` request body:
Example file:// request body:

```
file:///home/rti/config/service_my_resource.xml
```

Reply body

- Empty.

Return codes

The operation may return a reply with error if:

- The specified resource identifier does not exist.
- The specified configuration is schematically invalid.
- There was an error creating the resource object.

Get Resource

GET [resource_identifier]

Returns an equivalent XML string that represents the current state of the resource object configuration, including any updates performed during its lifecycle.

Request body

- Empty.

Reply body

- string_body: XML representation of the resource object.

Example reply body:

```
<my_resource name="MyObject">
  ...
</my_resource>
```

Return codes

The operation may return a reply with error if:

- The specified resource identifier does not exist.

Update Resource

UPDATE [resource_identifier]

Updates the specified resource object from its configuration in XML representation.

This operation modifies the properties of the resource object, including the associated configuration. Only the mutable properties of the resource class can be updated while the object is enabled. To update immutable properties, the resource object must be disabled first.
Implementations may validate the receive configuration against a scheme (DTD or XSD) that defines the valid set of accepted parameters (for example, only mutable elements).

**Request body**

- **string_body**: XML representation of the resource object provided as `file://` or `str://`.
  - Example `str://` request body:
    ```
    str://"<my_resource name="MyResourceObject">
    ...
    </my_resource>"
    ```
  - Example `file://` request body:
    ```
    file:///home/rti/config/service_update_my_resource.xml
    ```

**Reply body**

- Empty.

**Return codes**

The operation may return a reply with error if:

- The specified resource identifier does not exist.
- The specified configuration is schematically invalid.
- The specified configuration contains changes in immutable properties.
- There was an error updating the resource object.

**Set Resource State**

**UPDATE [resource_identifier]/state**

Sends a state change request to the specified resource object.

This operation attempts to change the state of the specified resource object and propagates the request to the resource object’s contained entities.

The target state must be one of the resource class’s valid accepted states.

**Request body**

- **octet_body**: CDR representation of an entity state.

**Reply body**

- Empty.

**Return codes**

The operation may return a reply with error if:

- The specified resource identifier does not exist.
- The target request is invalid.
The resource object reported an error while performing the state transition.

Delete Resource

DELETE [resource_identifier]
Deletes the specified resource object.

This operation deletes a resource object and its contained entities. The deleted object is removed from its parent resource object.

The associated object configuration is removed from the currently loaded full XML configuration.

After a successful deletion, the resource object is no longer addressable for additional remote access.

Request body
- Empty.

Reply body
- Empty.

Return codes
The operation may return a reply with error if:
- The specified resource identifier does not exist.
- There was an error deleting the resource object.

11.3 Monitoring Distribution Platform

Monitoring refers to the distribution of health status information metrics from instrumented RTI services. This section describes the architecture of the monitoring capability supported in RTI Routing Service and RTI Recording Service. You will learn what type of information these applications can provide and how to access it.

RTI services provide monitoring information through a Distribution Topic, which is a DDS Topic responsible for distributing information with certain characteristics about the service resources. An RTI service provides monitoring information through the following three distribution topics:

- **ConfigDistributionTopic**: Distributes metrics related to the description and configuration of a Resource. This information may be immutable or change rarely.
- **EventDistributionTopic**: Distributes metrics related to Resource status notifications of asynchronous nature. This information is provided asynchronously when Resources change after the occurrence of an event.
- **PeriodicDistributionTopic**: Distribute metrics related to periodic, sampling-based updates of a Resource. Information is provided periodically at a configurable publication period.

These three Topics are shared across all services for the distribution of the monitoring information. Table 11.6 provides a summary of these topics.
Table 11.6: Monitoring Distribution Topics

<table>
<thead>
<tr>
<th>Topic</th>
<th>Name</th>
<th>Top-level Type Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConfigDistributionTopic</td>
<td>rti/service/monitoring/config</td>
<td>rti::service::monitoring::Config</td>
</tr>
<tr>
<td>EventDistributionTopic</td>
<td>rti/service/monitoring/event</td>
<td>rti::service::monitoring::Event</td>
</tr>
<tr>
<td>PeriodicDistributionTopic</td>
<td>rti/service/monitoring/periodic</td>
<td>rti::service::monitoring::Periodic</td>
</tr>
</tbody>
</table>

Figure 11.5 shows the mapping of the monitoring information into the distribution Topics. A distribution Topic is keyed on service resources categorized as keyed Resources. These are resources whose related monitoring information is provided as an instance on the distribution Topic.

11.3.1 Distribution Topic Definition

All distribution Topics have a common type structure that is composed of two parts: a base type that identifies a resource object and a resource-specific type that contains actual status monitoring information.

The definition of a distribution Topic is shown in Figure 11.6.

Keyed Resource Base Type Fields

This is the base type of all distribution Topics and consists of two fields:

- **object_guid**: Key field. It represents a 16-byte sequence that uniquely identifies a Keyed Resource across all the available services in the monitoring domain. Hence, the associated instance handle key hash will be the same for all distribution Topics, allowing easy correlation
of a resource. It will also facilitate, as we will discuss later, easy instance data manipulation in a `DataReader`.

- `parent_guid`: It contains the object GUID of the parent resource. This field will be set to all zeros if the object is a top-level resource thus with no parent.

This base type, `KeyedResource`, is defined in `[NDDSHOME]/resource/idl/ServiceCommon.idl`.

### Resource-Specific Type Fields

This is the type that conveys monitoring information for a concrete resource object. Since a distribution `Topic` is responsible for providing information about different resource classes, the resource-specific type consists of a single field that is a **Union of all the possible representations** for the keyed resources that provide that on the topic.

As expected, there must be consistency between the two parts of the distribution topic type. That is, a sample for a concrete resource object must contain the resource-specific union discriminator corresponding to the resource object’s class.

### Example: Monitoring of Generic Application

Assume a generic application that provides monitoring information about the modes of transports `Car`, `Boat` and `Plane`. Each mode is mapped to a keyed resource, each with a custom type that contains metrics specific to each class.

The monitoring distribution `Topic` top-level type, `TransportModeDistribution`, would be defined as follows, using IDL v4 notation:

```idl
#include "ServiceCommon.idl"

@nested
struct CarType {
    float speed;
    String color;
    String plate_number;
}
```
struct BoatType {
    float knots;
    float latitude;
    float longitude;
};

struct PlaneType {
    float ground_speed;
    int32 air_track;
};

enum TransportModeKind {
    CAR_TRANSPORT_MODE,
    BOAT_TRANSPORT_MODE,
    PLANE_TRANSPORT_MODE
};

union TransportModeUnion switch (TransportModeKind) {
    case CAR_TRANSPORT_MODE:
        CarType car;
        break;
    case BOAT_TRANSPORT_MODE:
        BoatType boat;
        break;
    case PLANE_TRANSPORT_MODE:
        PlaneType plane;
    }

struct TransportModeDistribution : KeyedResource {
    TransportModeUnion value;
};

Assume now that in the monitoring domain there are three resource objects, one for each resource class: a Car object ‘CarA’, a Boat object ‘Boat1’, and a Plane object ‘PlaneX’. They all have unique resource GUIDs and each object represents an instance in the distribution Topic. The table shows the example of potential sample values:

Table 11.7: Samples in TransportModeDistribution Topic

<table>
<thead>
<tr>
<th>object_guid</th>
<th>CarA</th>
<th>Boat1</th>
<th>PlaneX</th>
</tr>
</thead>
<tbody>
<tr>
<td>parent_guid</td>
<td>0x00</td>
<td>0x00</td>
<td>0x00</td>
</tr>
<tr>
<td>value</td>
<td>CAR_TRANSPORT_MODE</td>
<td>BOAT_TRANSPORT_MODE</td>
<td>PLANE_TRANSPORT_MODE</td>
</tr>
<tr>
<td>discriminator</td>
<td>0x0C</td>
<td>0xAB</td>
<td>0xf2</td>
</tr>
</tbody>
</table>
11.3.2 DDS Entities

RTI services allow you to distribute monitoring information in any domain. For that, they create the following DDS entities:

- A DomainParticipant on the monitoring domain.
- A single Publisher for all DataWriters.
- A DataWriter for each distribution Topic.

A service will create these entities with default QoS or otherwise the corresponding service user's manual will specify the actual values. Services allow you to customize the QoS of the DDS entities, typically in the service monitoring configuration under the <monitoring> tag. You will need to refer to each service's user's manual.

11.3.3 Monitoring Metrics Publication

How services publish monitoring samples depends on the distribution Topic.

Configuration Distribution Topic

There are two events that cause the publication of samples in this topic:

- As soon as a Resource object is created. This event generates the first sample in the Topic for the resource object just created. Since these first samples are published as resources are created, it is guaranteed to be in hierarchical order; that is, the sample for a parent Resource is published before its children. When Resources are created depends on the service. Typically, Resources are created on service startup. Other cases include manual creation (e.g., through remote administration) or external event-driven creation (e.g., discovery of matching streams, in the case of AutoRoute in Routing Service).

- On Resource object update. This event occurs when the properties of the object change due to a set or update operation (e.g., through remote administration).

Event Distribution Topic

Services publish samples in this Topic in reaction to an internal event, such as a Resource state change. Which events and their associated information and when they occur is highly dependent on concrete service implementations.

Periodic Distribution Topic

Samples in this Topic are published periodically, according to a fixed configurable period. The metrics provided in this Topic are generated in two different ways:

- As a snapshot of the current value, taken at the publication time (e.g., current number of matching DataReaders). This represents a simple case and the metric is typically represented with an adequate primitive member.

- As a statistic variable generated from a set of discreet measurements, obtained periodically. This represents a continuous flow of metrics, represented with theStatisticVariable type (see Section 11.3.4).
There are two activities involved in the generation of the statistic variables: Calculation and Publication. All the configuration elements for these activities are available under the <monitoring> tag.

**Calculation**

The instrumented service periodically performs measurements on the metric. This activity is also known as sampling (don’t confuse with data samples). The frequency of the measurements can be configured with the tag <statistics_sampling_period>. As a general recommendation, the sampling period should be a few times smaller than the publication period. A small sampling period provides more accurate statistics generation at the expense of increasing memory and CPU consumption.

**Publication**

The service periodically publishes a data sample containing a snapshot of the statistics generated during the calculation phase. The publication period can be configured with the tag <statistics_publication_period>. The value of a statistic variable corresponds to the time window of a publication period.

### 11.3.4 Monitoring Metrics Reference

This section describes the types used as common metrics across services. All the type definitions listed here are in [NDDSHOME]/resource/idl/ServiceCommon.idl.

**Statistic Variable**
Listing 11.3: Statistics

```c
@appendable @nested
struct StatisticMetrics {
    int64 period_ms;
    int64 count;
    float mean;
    float minimum;
    float maximum;
    float std_dev;
};

@appendable @nested
struct StatisticVariable {
    StatisticMetrics publication_period_metrics;
};
```

Table 11.8: StatisticMetrics

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>period_ms</td>
<td>Period in milliseconds at which the metrics are published.</td>
</tr>
<tr>
<td>count</td>
<td>Sum of all the measurement values obtained during the publication period.</td>
</tr>
<tr>
<td>mean</td>
<td>Arithmetic mean of all the measurement values during publication period. For aggregated metrics, this value is the mean of all the aggregated metrics means.</td>
</tr>
<tr>
<td>min</td>
<td>Minimum of all the measurement values during publication period. For aggregated metrics, this value is the minimum of all the aggregated metrics minimums.</td>
</tr>
<tr>
<td>max</td>
<td>Maximum of all the measurement values during publication period. For aggregated metrics, this value is the maximum of all the aggregated metrics minimums.</td>
</tr>
<tr>
<td>std_dev</td>
<td>Standard deviation of all the measurement values during publication period. For aggregated metrics, this value is the standard deviation of all the aggregated metrics minimums.</td>
</tr>
</tbody>
</table>

Host Metrics

Listing 11.4: Host Types

```c
@appendable @nested
struct HostPeriodic {
    @optional StatisticVariable cpu_usage_percentage;
    @optional StatisticVariable free_memory_kb;
    @optional StatisticVariable free_swap_memory_kb;
    int32 uptime_sec;
};
```
Table 11.9: HostConfig

    @optional StatisticVariable bytes_per_sec;
    @optional StatisticVariable latency_millisec;
};
```

Table 11.15: NetworkPerformance

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>samples_per_sec</td>
<td>Statistic variable that provides information about the number of samples processed (received or sent) per second.</td>
</tr>
<tr>
<td>bytes_per_sec</td>
<td>Statistic variable that provides information about the number of bytes processed (received or sent) per second.</td>
</tr>
<tr>
<td>latency_millisec</td>
<td>Statistic variable that provides information about the latency in milliseconds for the data processed. The latency in a refers to the total time elapsed during the associated processing of the data, which depends on the type of application.</td>
</tr>

Release Notes

12.1 Supported Platforms

RTI Routing Service is supported on the platforms in Table 12.1.

It can also be deployed as a C library linked into your application. This is true for all platforms in Table 12.1 except INTEGRITY.

Table 12.1: Supported Platforms

<table>
<thead>
<tr>
<th>Platform</th>
<th>Operating System</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGRITY®</td>
<td>INTEGRITY 10.0.2 on x86 CPU</td>
</tr>
<tr>
<td></td>
<td>INTEGRITY 11.0.4 on x86 CPU</td>
</tr>
<tr>
<td>Linux®</td>
<td>All Linux platforms in the RTI Connext DDS Core Libraries Release Notes for the same version number, except not supported on SUSE® Linux Enterprise Server or Wind River® Linux 7.</td>
</tr>
<tr>
<td>OS X®</td>
<td>All OS X platforms in the RTI Connext DDS Core Libraries Release Notes for the same version number.</td>
</tr>
<tr>
<td>Windows®</td>
<td>All Windows platforms in the RTI Connext DDS Core Libraries Release Notes for the same version number.</td>
</tr>
</tbody>
</table>

Routing Service is also supported on the platforms in Table 12.2; these are target platforms for which RTI offers custom support. If you are interested in these platforms, please contact your local RTI representative or email sales@rti.com.

Table 12.2: Custom Platforms

</tbody>
</table>
12.2 Compatibility

For backward compatibility information between Routing Service 6.0.0 and previous releases, please see the Migration Guide on the RTI Community portal.

Routing Service can be used to forward and transform data between applications built with Connext DDS, as well as RTI Data Distribution Service 4.5[b-e], 4.4d, 4.3e, and 4.2e except as noted below.

- Routing Service is not compatible with applications built with RTI Data Distribution Service 4.5e and earlier releases when communicating over shared memory. For more information, please see the Transport Compatibility section in the Migration Guide on the RTI Community portal.

- Starting in Connext DDS 5.1.0, the default message_size_max for the UDPv4, UDPv6, TCP, Secure WAN, and shared-memory transports changed to provide better out-of-the-box performance. Routing Service also uses the new value for message_size_max. Consequently, Routing Service is not out-of-the-box compatible with applications running older versions of Connext DDS. Please see the RTI Connext DDS Core Libraries Release Notes for instructions on how to resolve this compatibility issue with older Connext DDS applications.

- The types of the remote administration and monitoring topics in 5.1.0 are not compatible with 5.0.0. Therefore:
  - The 5.0.0 RTI Routing Service shell, RTI Admin Console 5.0.0, and RTI Connext DDS 5.0.0 user applications performing monitoring/administration are not compatible with RTI Routing Service 5.1.0.
  - The 5.1.0 RTI Routing Service shell, RTI Admin Console 5.1.0, and RTI Connext DDS 5.1.0 user applications performing monitoring/administration are not compatible with RTI Routing Service 5.0.0.

12.3 What’s New in 6.0.0

12.3.1 New platforms

Routing Service is now supported on the platforms in Table 12.3. For more information, see the Connext DDS Core Libraries Platform Notes.

<table>
<thead>
<tr>

<tr>
<td></td>
<td>Wind River Linux 8 on ARMv7 (custom support)</td>
</tr>
</tbody>
</table>

12.3.2 Support for multiple connections in a domain route

Routing Service has been enhanced to support the creation of more than two connections within a domain route. This includes the ability to specify more than two builtin DDS adapter Domain-Participants.

The XML tags <connection_1>, <connection_2>, <participant_1> and <participant_2> have been deprecated. Routing Service will still load legacy configurations, but support may be dropped.
in future releases. Instead of these tags, new tags <connection> and <participant> have been introduced. They are defined just like the legacy tags, with the addition of a mandatory ‘name’ attribute. This attribute is used by a route’s input and output to indicate the connection the inputs and outputs are created from. For example, the snippet below defines a domain route with two participants and a custom, adapter-based connection:

```xml
<domain_route name="MyDomainRoute">
  <participant name="participant_0">
    ...
  </participant>
  <participant name="participant_1">
    ...
  </participant>
  <connection name="customConnection">
    plugin_name="MyAdapterPlugin"
    ...
  </connection>
</domain_route>
```

See Section 3.5.4.

12.3.3 Support for multiple inputs and outputs in routes or topic routes

Routing Service has been enhanced to support the creation of multiple inputs and outputs in a route. This enhancement includes the ability to specify more than one built-in DDS adapter DataReader (<input>, <dds_input>) and DataWriter (<output>, <dds_output>).

For example, the snippet below defines a topic route with a single input in domain 0 and two outputs in domains 1 and 2 (assume the participants for each input and output have been previously defined):

```xml
<topic_route name="Route">
  <input participant="domain_0">
    <topic_name>TopicA</topic_name>
    <registered_type_name>MyType</registered_type_name>
    ...
  </input>
  <output participant="domain_1">
    <topic_name>TopicB</topic_name>
    <registered_type_name>MyType</registered_type_name>
    ...
  </output>
  <output participant="domain_2">
    <topic_name>TopicA</topic_name>
    <registered_type_name>MyType</registered_type_name>
    ...
  </output>
</topic_route>
```
12.3.4 Support for C++ Adapter, Transformation and Service APIs

Adapter, Transformation and Service APIs are now supported in C++.

See Section 6.

12.3.5 New pluggable processor API

One of the star features of Routing Service is a new pluggable component, the Processor, which allows you to control the operation and data forwarding logic of Routes.

A Processor defines an interface with access to the Route and its inputs and outputs, allowing you to read, manipulate, and write user data under events such as data arrival or periodic notification.

For example, the following snippet shows a simple example of data aggregation:

```cpp
on_data_available(Route& route) {
    auto output = route.output<DynamicData>("info");
    auto info = output.create_data();
    for(const auto& status : route.input<DynamicData>("status_in").take()) {
        auto periodic = route.input<DynamicData>("periodic_in")
            .select(status.info().instance_handle()).take();
        info.value<int>("id", status.data().get<int>("id");
        info.value<int>("config", status.data().get<string>("config"));
        info.value<int>("latency", periodic[0].data().get<int>("latency"));
        output.write(info);
    }
}
```

See Section 6.

12.3.6 Redesigned remote administration architecture

Routing Service’s remote administration functionality has been redesigned to have a new, consistent, more usable and scalable architecture. Among the changes in this evolution, it includes:

- A homogenous API based on REST that standardizes the mechanism to invoke remote operations on the service entities.
- A common DDS communication model based on Connext DDS Request-Reply, which is service-independent and represents a common communication channel for all RTI services.
- Enhanced administration Topic definitions for increased scalability, with support for content-filtering and instance management.
12.3.7 Redesigned remote monitoring architecture

Routing Service’s remote monitoring functionality has been redesigned to have a new, consistent, more usable and scalable architecture. Among the changes in this evolution, it includes:

- A common DDS communication model that defines only three Topics to provide all the monitoring information from the service entities. This DDS model is service-independent and a common communication channel for all RTI services.
- Enhanced monitoring Topic definitions to represent a more scalable, instance-based mapping between the service entities and their associated monitoring entities.

See Section 5.

12.3.8 Support for advanced logging

Routing Service internal logging has improved to provide more detailed logging context. With advanced logging, all the operation logs will be part of an activity context that contains information about the entity and the operation. This facilitates the identification of potential issues in the configuration or runtime behavior.

For example, the following log message:

```
[/routing_services/default|CREATE]
```

represents a context of a Routing Service create operation. Then any logs generated by operations occurring in this context will be appended to the activity context. For example:

```
[/routing_services/default|CREATE] load URL group='../../../resource/xml/RTI_ROUTING_SERVICE.xml'
```

12.3.9 Support for XML variables expansion from command-line and service API

XML configuration variables defined in the form

```<element>$(MY_VAR)</element>```

can be expanded, in addition to the existing runtime shell environment, from two new mechanisms:

- A new command-line option, using the notation `-DMY_VAR=my_value`
- A new `ServiceProperty::user_environment` member, which represents a map of variable name-value pairs.

See Section 2.

12.3.10 Paused and disabled state is cleared after disabling an entity

In previous releases, Routing Service remembered the paused state of an entity that was disabled. When that entity was re-enabled, it entered the paused or disabled state. This behavior has
changed, so that now the paused state is cleared and if the entity is re-enabled, it will not enter the paused state.

This same behavior affected the child entities of the disabled entity. After re-enabling the entity, *Routing Service* remembered its state and re-enabled the child entities. This behavior has changed, so that after enabling an entity, each of its child entities is enabled based its own ‘enabled’ attribute.

### 12.3.11 Removed warning caused by multiple registrations of a type

*Routing Service* with Routes using the DDS adapter may have output the following message:

```
PRESParticipant_registerType:name 'MyTypeRegisteredName' is not unique
```

This was caused by multiple registrations of the same type with the same registered name. This behavior has changed and the warning has been removed.

### 12.4 What’s Fixed in 6.0.0

#### 12.4.1 Remotely disabling TopicRoute/Route could fail while forwarding data

A remote command to disable a TopicRoute or Route may have resulted in an error if the TopicRoute or Route was receiving data at a high rate. In this case, the TopicRoute or Route remained enabled and kept forwarding data. This problem has been resolved.

[RTI Issue ID ROUTING-531]

#### 12.4.2 Routing Service in debug mode did not link with debug version of Distributed Logger

The debug version of *Routing Service* linked with the release version of the RTI Distributed Logger library, rather than the debug version. This may have lead to unexpected behavior, including potential segmentation faults. This problem has been resolved.

[RTI Issue ID ROUTING-533]

#### 12.4.3 Route stream matching not applied correctly in presence of certain partitions

When partitions in either the publication or subscription side were composed of patterns only, route streams would not match correctly. This problem has been resolved.

[RTI Issue ID ROUTING-538]

#### 12.4.4 Crash on shutdown if types provided through both discovery and XML

*Routing Service* could have randomly crashed during shutdown if it obtained types from both discovery and XML configuration. This problem has been resolved.

[RTI Issue ID ROUTING-539]
12.4.5 Sample loan not returned to DDS input upon DDS_DataReader::get_key() failure

TopicRoutes did not return the sample loan to the DDS inputs if the StreamReader::read() operation failed due to DataReader::get_key() failures.

This situation could occur very rarely and only if the same StreamReader::read() call returned valid samples in combination with samples discarded by a get_key() failure.

This problem could cause memory growth and errors upon service shutdown. For example, the following logs were the output upon service shutdown:

```
[D0330|DELETE_CONTAINED] PRES PsService_destroyAllLocalEndpointsInGroupWithCursor!:delete local reader
[D0330|DELETE_CONTAINED] PRES PsService_destroyAllEntities!:destroyAllLocalEndpointsInGroupWithCursor
[D0330|DELETE_CONTAINED] PRESParticipant_destroyAllEntities!:delete service entities
[D0330|DELETE_CONTAINED] PRESParticipant_destroyAllEntities!:delete topic
[D0330|DELETE_CONTAINED] DDS_DomainParticipant_delete_contained_entities!:delete contained entities
```

This problem has been resolved.

[RTI Issue ID ROUTING-552]

12.4.6 Enabling monitoring through ServiceProperty::enable_monitoring only worked if <monitoring> tag present

Enabling monitoring by setting ServiceProperty::enable_monitoring did not take effect unless the <monitoring> tag was also part of the XML configuration. This problem has been resolved.

[RTI Issue ID ROUTING-564]

12.4.7 Logged message included inaccurate number of dropped samples

Routing Service logged a message for a StreamWriter::write failure that included an inaccurate number of dropped samples. For example:

```
ROUTERRoutingProcessor_routeToMatchingOutputs: write error on output at index 1. 1024 samples have been dropped
```

This problem has been resolved.

[RTI Issue ID ROUTING-572]

12.4.8 Deserialization errors may have occurred under some conditions

Routing Service generated deserialization errors if a publication type was compatible but different than the TopicRoute’s input type, and the TopicRoute’s input was created after the discovery of such publication type. This situation was unlikely to occur. This problem has been resolved.

[RTI Issue ID ROUTING-578]
12.4.9 TopicRoutes with TopicQuery proxy mode enabled forwarded live data only to first output

A TopicRoute with multiple outputs that enabled TopicQuery proxy mode forwarded live data only to the first output. This problem has been resolved; live data is now forwarded to all outputs.

[RTI Issue ID ROUTING-579]

12.4.10 Routing Service Java API did not work with some TypeCodes

Types larger than 65,535 bytes and types that used extensible type features only available in TypeObject weren’t properly serialized when using Routing Service’s Java API. This issue caused participant creation to produce a BAD_TYPECODE exception for large types and could have prevented communication between Java applications and applications using a different language binding for types using extensibility features. This problem has been resolved.

[RTI Issue ID ROUTING-583]

12.5 Known Issues

12.5.1 QoS Topic Filters Not Supported

If the QoS for an Input or Output entity inherits from a base QoS profile that specifies topic filters, these will be ignored in the process of selecting the final parent QoS element.

If the base QoS profile contains multiple QoS elements applicable to an Input or Output, you will need to inherit by specifying the fully qualified name of the desired QoS base element.
