## Trademarks

RTI, Real-Time Innovations, Connex, NDDS, the RTI logo, 1RTI and the phrase, “Your Systems. Working as one,” are registered trademarks, trademarks or service marks of Real-Time Innovations, Inc. All other trademarks belong to their respective owners.

## Copy and Use Restrictions

No part of this publication may be reproduced, stored in a retrieval system, or transmitted in any form (including electronic, mechanical, photocopy, and facsimile) without the prior written permission of Real-Time Innovations, Inc. The software described in this document is furnished solely under and subject to RTI's standard terms and conditions available at <https://www.rti.com/terms> and in accordance with your License Acknowledgement Certificate (LAC) and Maintenance and Support Certificate (MSC), except to the extent otherwise accepted in writing by a corporate officer of RTI.

This is an independent publication and is neither affiliated with, nor authorized, sponsored, or approved by, Microsoft Corporation.

The security features of this product include software developed by the OpenSSL Project for use in the OpenSSL Toolkit (<http://www.openssl.org/>). This product includes cryptographic software written by Eric Young (eay@cryptsoft.com). This product includes software written by Tim Hudson (tjh@cryptsoft.com).

## Notices

### *Deprecations and Removals*

Any deprecations or removals noted in this document serve as notice under the Real-Time Innovations, Inc. Maintenance Policy #4220 and/or any other agreements by and between RTI and customer regarding maintenance and support of RTI's software.

*Deprecated* means that the item is still supported in the release, but will be removed in a future release. *Removed* means that the item is discontinued or no longer supported. By specifying that an item is deprecated in a release, RTI hereby provides customer notice that RTI reserves the right after one year from the date of such release and, with or without further notice, to immediately terminate maintenance (including without limitation, providing updates and upgrades) for the item, and no longer support the item, in a future release.

### *Early Access Software*

“Real-Time Innovations, Inc. (“RTI”) licenses this Early Access release software (“Software”) to you subject to your agreement to all of the following conditions:

- (1) you may reproduce and execute the Software only for your internal business purposes, solely with other RTI software licensed to you by RTI under applicable agreements by and between you and RTI, and solely in a non-production environment;
- (2) you acknowledge that the Software has not gone through all of RTI’s standard commercial testing, and is not maintained by RTI’s support team;
- (3) the Software is provided to you on an “AS IS” basis, and RTI disclaims, to the maximum extent permitted by applicable law, all express and implied representations, warranties and guarantees, including without limitation, the implied warranties of merchantability, fitness for a particular purpose, satisfactory quality, and non-infringement of third party rights;
- (4) any such suggestions or ideas you provide regarding the Software (collectively , “Feedback”), may be used and exploited in any and every way by RTI (including without limitation, by granting sub-licenses), on a non-exclusive, perpetual, irrevocable, transferable, and worldwide basis, without any compensation, without any obligation to report on such use, and without any other restriction or obligation to you; and
- (5) TO THE MAXIMUM EXTENT PERMITTED BY APPLICABLE LAW, IN NO EVENT WILL RTI BE LIABLE TO YOU FOR ANY DIRECT, INDIRECT, SPECIAL, INCIDENTAL, EXEMPLARY OR PUNITIVE OR CONSEQUENTIAL DAMAGES OF ANY KIND, OR FOR LOST PROFITS, LOST DATA, LOST REPUTATION, OR COST OF COVER, REGARDLESS OF THE FORM OF ACTION WHETHER IN CONTRACT, TORT (INCLUDING WITHOUT LIMITATION, NEGLIGENCE), STRICT PRODUCT LIABILITY OR OTHERWISE, WHETHER ARISING OUT OF OR RELATING TO THE USE OR INABILITY TO USE THE SOFTWARE, EVEN IF RTI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.”

# Available Documentation

To get you up and running as quickly as possible, the *RTI® Connex® DDS* documentation is divided into several parts.

- [RTI Connex Installation Guide](#) — This document describes how to install *Connex*, as well as License Management.
- [RTI Connex Getting Started Guide](#) — This document describes the core values and concepts behind the product and takes you step-by-step through the creation of a simple example application. Addendums cover:
  - [RTI Connex Core Libraries Getting Started Guide Addendum for Android Systems](#)
  - [RTI Connex Core Libraries Getting Started Guide Addendum for Embedded Systems](#)
- [RTI Connex Core Libraries What's New in 7.0.0](#)— This document describes changes and enhancements in the most recent major release of *Connex*. Those upgrading from a previous version should read this document first.
- [RTI Connex Core Libraries Release Notes](#) —This document describes system requirements, what's fixed, and known issues.
- [RTI Connex Core Libraries Platform Notes](#) — This document provides platform-specific information, including specific information required to build your applications using *Connex*, such as compiler flags and libraries.
- *Migration Guide* on the RTI Community Portal (<https://community.rti.com/documentation>)—This document describes how to migrate to the current release from a previous *Connex* release, including what compatibility issues you may need to account for during your upgrade. This guide is updated as needed.
- *RTI Connex Core Libraries User's Manual* — This document describes the features of the product and how to use them. It is organized around the structure of the *Connex* APIs and certain common high-level tasks.

- 
- [RTI Connex Core Libraries Extensible Types Guide](#) — This document describes how to use Extensible Types, which allow you to define data types in a more flexible way, and to evolve data types over time without giving up portability, interoperability, or the expressiveness of the DDS type system.
  - **API Reference HTML Documentation** ([README.html](#)) — This extensively cross-referenced documentation, available for all supported programming languages, is your in-depth reference to every operation and configuration parameter in the middleware. Even experienced *Connex* developers will often consult this information.
  - **The Programming How To's provide a good place to begin learning the APIs.** These are hyperlinked code snippets to the full API documentation. From the **README.html** file, select one of the supported programming languages, then scroll down to the Programming How To's. Start by reviewing the Publication Example and Subscription Example, which provide step-by-step examples of how to send and receive data with *Connex*.

Many readers will also want to look at additional documentation available online. In particular, RTI recommends the following:

- Use the [RTI Customer Portal \(http://support.rti.com\)](http://support.rti.com) to download RTI software and contact RTI Support. The RTI Customer Portal requires a username and password. You will receive this in the email confirming your purchase. If you do not have this email, please contact [license@rti.com](mailto:license@rti.com). Resetting your login password can be done directly at the RTI Customer Portal.
- The RTI Community Portal (<https://community.rti.com>) provides a wealth of knowledge to help you use *Connex*, including:
  - Documentation, at <https://community.rti.com/documentation>
  - Best Practices
  - Example code for specific features, as well as more complete use-case examples,
  - Solutions to common questions,
  - A glossary,
  - Downloads of experimental software,
  - And more.
- Whitepapers and other articles are available from <http://www.rti.com/resources>.

# Contents

---

<b>About this Document</b>	
Paths Mentioned in Documentation .....	1
Programming Language Conventions .....	2
Traditional vs. Modern C++ .....	2
Extensions to the DDS Standard .....	3
Environment Variables .....	3
Additional Resources .....	4
<b>Part 1: Connex Overview</b> .....	<b>5</b>
<b>Chapter 1 What is Connex?</b> .....	<b>1</b>
<b>Chapter 2 Features of Connex</b> .....	<b>2</b>
<b>Chapter 3 Connex Communication Model</b> .....	<b>4</b>
<b>Chapter 4 Network Communications Models</b> .....	<b>7</b>
<b>Chapter 5 What is a Databus?</b>	
5.1 Difference between Database and Databus .....	12
5.2 Layered Databus .....	13
<b>Chapter 6 DDS Data Types</b> .....	<b>15</b>
<b>Chapter 7 Data Topics</b> .....	<b>16</b>
<b>Chapter 8 DDS Samples, Instances, and Keys</b> .....	<b>17</b>
<b>Chapter 9 DataWriters/Publishers and DataReaders/Subscribers</b> .....	<b>20</b>
<b>Chapter 10 DDS Entities</b> .....	<b>24</b>
<b>Chapter 11 Quality of Service (QoS)</b> .....	<b>26</b>
<b>Chapter 12 DDS Domains and DomainParticipants</b> .....	<b>28</b>
<b>Chapter 13 Application Discovery</b> .....	<b>29</b>
<b>Chapter 14 XML Configuration</b> .....	<b>30</b>
<b>Part 2: Building Blocks of Connex: Entities and Domains</b> .....	<b>31</b>
<b>Chapter 15 Working with DDS Entities</b>	

---

15.1 Creating and Deleting DDS Entities .....	33
15.2 Enabling DDS Entities .....	35
15.2.1 Rules for Calling enable() .....	36
15.3 Getting an Entity's Instance Handle .....	37
15.4 Getting Status and Status Changes .....	38
15.5 Getting and Setting Listeners .....	38
15.6 Getting the StatusCondition .....	39
15.7 Statuses .....	39
15.7.1 Types of Communication Status .....	40
15.7.2 Special Status-Handling Considerations for C .....	45
15.8 Listeners .....	46
15.8.1 Types of Listeners .....	47
15.8.2 Creating and Deleting Listeners .....	49
15.8.3 Special Considerations for Listeners in C .....	49
15.8.4 Special Considerations for Listeners in Modern C++ .....	50
15.8.5 Hierarchical Processing of Listeners .....	51
15.8.6 Operations Allowed within Listener Callbacks .....	53
15.8.7 Best Practices with Listeners .....	53
15.8.8 Exclusive Areas (EAs) .....	54
15.9 Conditions and WaitSets .....	59
15.9.1 Creating and Deleting WaitSets .....	60
15.9.2 WaitSet Operations .....	61
15.9.3 Waiting for Conditions .....	62
15.9.4 Processing Triggered Conditions—What to do when Wait() Returns .....	63
15.9.5 Conditions and WaitSet Example .....	64
15.9.6 GuardConditions .....	66
15.9.7 ReadConditions and QueryConditions .....	66
15.9.8 StatusConditions .....	69
15.9.9 Using Both Listeners and WaitSets .....	71
15.10 Getting, Setting, and Comparing QosPolicies .....	71
<b>Chapter 16 Working with DDS Domains</b>	
16.1 Fundamentals of DDS Domains and DomainParticipants .....	72
16.2 DomainParticipantFactory .....	75
16.2.1 Setting DomainParticipantFactory QosPolicies .....	77
16.2.2 Getting and Setting Default QoS for DomainParticipants .....	79
16.2.3 Freeing Resources Used by the DomainParticipantFactory .....	79

---

16.2.4	Looking Up DomainParticipants .....	80
16.2.5	Getting QoS Values from a QoS Profile .....	80
16.3	DomainParticipants .....	81
16.3.1	Creating a DomainParticipant .....	87
16.3.2	Deleting DomainParticipants .....	89
16.3.3	Deleting Contained Entities .....	90
16.3.4	Choosing a Domain ID and Creating Multiple DDS Domains .....	90
16.3.5	Isolating DomainParticipants and Endpoints from Each Other .....	91
16.3.6	Setting Up DomainParticipantListeners .....	94
16.3.7	Setting DomainParticipant QoS Policies .....	96
16.3.8	Looking up Topic Descriptions .....	102
16.3.9	Finding a Topic .....	102
16.3.10	Getting the Implicit Publisher or Subscriber .....	103
16.3.11	Asserting Liveliness .....	104
16.3.12	Learning about Discovered DomainParticipants .....	104
16.3.13	Learning about Discovered Topics .....	104
16.3.14	Getting Participant Protocol Status .....	105
16.3.15	Configuring the Clock per DomainParticipant .....	105
16.3.16	Other DomainParticipant Operations .....	106
16.4	System Properties .....	107
<b>Part 3:</b>	<b>Working with Data in Connex</b> .....	<b>109</b>
<b>Chapter 17</b>	<b>Data Types and DDS Data Samples</b>	
17.1	Introduction to the Type System .....	112
17.1.1	Sequences .....	113
17.1.2	Strings and Wide Strings .....	115
17.1.3	Introduction to TypeCode .....	120
17.2	Built-in Data Types .....	121
17.2.1	Registering Built-in Types .....	122
17.2.2	Creating Topics for Built-in Types .....	122
17.2.3	String Built-in Type .....	123
17.2.4	KeyedString Built-in Type .....	128
17.2.5	Octets Built-in Type .....	134
17.2.6	KeyedOctets Built-in Type .....	139
17.2.7	Managing Memory for Built-in Types .....	147
17.2.8	Type Codes for Built-in Types .....	152
17.3	Creating User Data Types with IDL .....	153

---

17.3.1	Variable-Length Types	155
17.3.2	Value Types	156
17.3.3	Type Codes	157
17.3.4	Translations for IDL Types	157
17.3.5	Escaped Identifiers	193
17.3.6	Namespaces In IDL Files	193
17.3.7	Referring to Other IDL Files	195
17.3.8	Preprocessor Directives	196
17.3.9	Using Builtin Annotations	197
17.4	Creating User Data Types with Extensible Markup Language (XML)	205
17.4.1	Mapping Type System Constructs to XML	206
17.5	Creating User Data Types with XML Schemas (XSD)	215
17.5.1	Primitive Types	233
17.6	Using RTI Code Generator (rtiddsgen)	234
17.7	Using Generated Types without Connex (Standalone)	234
17.7.1	Using Standalone Types in C	234
17.7.2	Using Standalone Types in C++	235
17.7.3	Standalone Types in Java	235
17.8	Interacting Dynamically with User Data Types	236
17.8.1	Type Schemas and TypeCode Objects	236
17.8.2	Defining New Types	236
17.8.3	Sending Only a Few Fields	238
17.8.4	Sending Type Information on the Network	238
17.9	Working with DDS Data Samples	240
17.9.1	Objects of Concrete Types	240
17.9.2	Objects of Dynamically Defined Types	242
17.9.3	Serializing and Deserializing Data Samples	244
17.9.4	Accessing the Discriminator Value in a Union	245
17.10	Data Sample Serialization Limits	245
<b>Chapter 18 Working with Topics</b>		
18.1	Topics	246
18.1.1	Creating Topics	248
18.1.2	Deleting Topics	250
18.1.3	Setting Topic QoS Policies	250
18.1.4	Copying QoS From a Topic to a DataWriter or DataReader	254
18.1.5	Setting Up TopicListeners	255

18.1.6 Navigating Relationships Among Entities .....	255
18.2 Status Indicator for Topics .....	255
18.2.1 INCONSISTENT_TOPIC Status .....	256
18.3 ContentFilteredTopics .....	256
<b>Chapter 19 Working with Instances</b>	
19.1 Instance States .....	258
19.1.1 ALIVE Details .....	259
19.1.2 NOT_ALIVE_DISPOSED Details .....	259
19.1.3 NOT_ALIVE_NO_WRITERS Details .....	261
19.1.4 Transitions between NOT_ALIVE States .....	262
19.2 QoS Configuration and Instances .....	264
19.2.1 QoS Policies that are Applied per Instance .....	264
19.2.2 QoS Policies that Affect Instance Management .....	266
19.3 Instance Metadata Memory Management .....	268
<b>Chapter 20 Sample and Instance Memory Management</b>	
20.1 Sample Memory Management for DataWriters .....	271
20.1.1 Memory Management without Batching .....	272
20.1.2 Memory Management with Batching .....	274
20.1.3 Writer-Side Memory Management when Using Java .....	276
20.1.4 Writer-Side Memory Management when Working with Large Data .....	276
20.2 Sample Memory Management for DataReaders .....	278
20.2.1 Memory Management for DataReaders Using Generated Type-Plugins .....	279
20.2.2 Reader-Side Memory Management when Using Java .....	280
20.2.3 Memory Management for DynamicData DataReaders .....	280
20.2.4 Memory Management for Fragmented DDS Samples .....	283
20.2.5 Reader-Side Memory Management when Working with Large Data .....	283
20.3 Instance Memory Management for DataWriters .....	285
20.4 Instance Memory Management for DataReaders .....	285
<b>Chapter 21 Mechanisms for Achieving Information Durability and Persistence</b>	
21.1 Overview .....	288
21.1.1 Scenario 1. DataReader Joins after DataWriter Restarts (Durable Writer History) .....	289
21.1.2 Scenario 2: DataReader Restarts While DataWriter Stays Up (Durable Reader State) .....	291
21.1.3 Scenario 3. DataReader Joins after DataWriter Leaves Domain (Durable Data) .....	292
21.2 Durability and Persistence Based on Virtual GUIDs .....	293
21.3 Durable Writer History .....	295
21.3.1 Durable Writer History Use Case .....	296

21.3.2	How To Configure Durable Writer History .....	297
21.4	Durable Reader State .....	299
21.4.1	Durable Reader State With Protocol Acknowledgment .....	300
21.4.2	Durable Reader State with Application Acknowledgment .....	301
21.4.3	Durable Reader State Use Case .....	302
21.4.4	How To Configure a DataReader for Durable Reader State .....	303
21.5	Data Durability .....	304
21.5.1	RTI Persistence Service .....	305
<b>Part 4:</b>	<b>Getting Applications to Discover Each Other .....</b>	<b>308</b>
<b>Chapter 22</b>	<b>Discovery Overview</b>	
22.1	Simple Participant Discovery .....	310
22.2	(Experimental) Simple Participant Discovery 2.0 .....	311
22.2.1	Bootstrap Message Fields .....	315
22.2.2	Configuration Message Fields .....	316
22.2.3	Unsupported Features with SPDP2 .....	317
22.2.4	Planned Improvements to SPDP2 .....	317
22.3	Simple Endpoint Discovery .....	317
<b>Chapter 23</b>	<b>Ports Used for Discovery</b>	
23.1	Inbound Ports for Meta-Traffic .....	321
23.2	Inbound Ports for User Traffic .....	321
23.3	Automatic Selection of participant_id and Port Reservation .....	322
23.4	Tuning domain_id_gain and participant_id_gain .....	322
<b>Chapter 24</b>	<b>Configuring the Peers List Used in Discovery</b>	
24.1	Peer Descriptor Format .....	326
24.1.1	Locator Format .....	327
24.1.2	Address Format .....	328
24.2	NDDS_DISCOVERY_PEERS Environment Variable Format .....	328
24.3	NDDS_DISCOVERY_PEERS File Format .....	329
<b>Chapter 25</b>	<b>Discovery: Under the Hood</b>	
25.1	Participant Discovery .....	332
25.1.1	Refresh Mechanism .....	336
25.1.2	Maintaining DataWriter Liveliness for kinds AUTOMATIC and MANUAL_BY_PARTICIPANT .....	338
25.2	Endpoint Discovery .....	341
25.3	Discovery Traffic Summary .....	346
25.4	Discovery-Related QoS .....	346
25.5	Debugging Discovery .....	347
<b>Chapter 26</b>	<b>Discovered RTPS Locators and Changes with IP Mobility</b>	

26.1 Locator Changes at Run Time .....	348
26.1.1 Locator Changes in IP-Based Transports .....	348
26.2 Detection of Unreachable Locators .....	350
26.3 Using DNS Tracker to Keep Peer List Updated .....	350
<b>Chapter 27 Restricting Communication—Ignoring Entities</b>	
27.1 Ignoring Specific Remote DomainParticipants .....	353
27.2 Ignoring Publications and Subscriptions .....	354
27.3 Ignoring Topics .....	355
27.4 Resource Limits Considerations for Ignored Entities .....	356
27.5 Supervising Endpoint Discovery .....	356
<b>Chapter 28 Accessing Discovery Information through Built-In Topics</b>	
28.1 Listeners for Built-in Entities .....	359
28.2 Built-in DataReaders .....	360
28.2.1 LOCATOR_FILTER QoS Policy (DDS Extension) .....	367
28.3 Accessing the Built-in Subscriber .....	368
<b>Part 5: Sending Data with Connex</b> .....	<b>370</b>
<b>Chapter 29 Overview of Sending Data</b> .....	<b>371</b>
<b>Chapter 30 Publishers</b>	
30.1 Creating Publishers Explicitly vs. Implicitly .....	376
30.2 Creating Publishers .....	377
30.3 Deleting Publishers .....	378
30.3.1 Deleting Contained DataWriters .....	379
30.4 Setting Publisher QoS Policies .....	379
30.4.1 Configuring QoS Settings when the Publisher is Created .....	380
30.4.2 Comparing QoS Values .....	382
30.4.3 Changing QoS Settings After the Publisher Has Been Created .....	382
30.4.4 Getting and Setting the Publisher’s Default QoS Profile and Library .....	383
30.4.5 Getting and Setting Default QoS for DataWriters .....	383
30.4.6 Other Publisher QoS-Related Operations .....	384
30.5 Setting Up PublisherListeners .....	385
30.6 Finding a Publisher’s Related DDS Entities .....	387
30.7 Waiting for Acknowledgments in a Publisher .....	387
30.8 Statuses for Publishers .....	388
30.9 Suspending and Resuming Publications .....	388
<b>Chapter 31 DataWriters</b>	
31.1 Creating DataWriters .....	393
31.2 Getting All DataWriters .....	395

---

31.3 Deleting DataWriters .....	395
31.4 Setting Up DataWriterListeners .....	395
31.5 Checking DataWriter Status .....	396
31.6 Statuses for DataWriters .....	397
31.6.1 APPLICATION_ACKNOWLEDGMENT_STATUS .....	398
31.6.2 DATA_WRITER_CACHE_STATUS .....	398
31.6.3 DATA_WRITER_PROTOCOL_STATUS .....	399
31.6.4 LIVELINESS_LOST Status .....	403
31.6.5 OFFERED_DEADLINE_MISSED Status .....	404
31.6.6 OFFERED_INCOMPATIBLE_QOS Status .....	404
31.6.7 PUBLICATION_MATCHED Status .....	405
31.6.8 RELIABLE_WRITER_CACHE_CHANGED Status (DDS Extension) .....	406
31.6.9 RELIABLE_READER_ACTIVITY_CHANGED Status (DDS Extension) .....	408
31.6.10 SERVICE_REQUEST_ACCEPTED Status (DDS Extension) .....	408
31.7 Using a Type-Specific DataWriter (FooDataWriter) .....	409
31.8 Writing Data .....	410
31.8.1 Blocking During a write() .....	412
31.8.2 write() behavior with KEEP_LAST and KEEP_ALL .....	413
31.9 Flushing Batches of DDS Data Samples .....	416
31.10 Writing Coherent Sets of DDS Data Samples .....	417
31.11 Waiting for Acknowledgments in a DataWriter .....	417
31.12 Application Acknowledgment .....	418
31.12.1 Application Acknowledgment Kinds .....	418
31.12.2 Explicitly Acknowledging a Single DDS Sample (C++) .....	419
31.12.3 Explicitly Acknowledging All DDS samples (C++) .....	420
31.12.4 Notification of Delivery with Application Acknowledgment .....	420
31.12.5 Application-Level Acknowledgment Protocol .....	421
31.12.6 Periodic and Non-Periodic AppAck Messages .....	422
31.12.7 Application Acknowledgment and Persistence Service .....	423
31.12.8 Application Acknowledgment and Routing Service .....	423
31.13 Required Subscriptions .....	424
31.13.1 Named, Required and Durable Subscriptions .....	424
31.13.2 Durability QoS and Required Subscriptions .....	425
31.13.3 Required Subscriptions Configuration .....	425
31.14 Managing Instances (Working with Keyed Data Types) .....	425
31.14.1 Writing Instances .....	426

31.14.2	Registering Instances	426
31.14.3	Disposing Instances	428
31.14.4	Unregistering Instances	429
31.14.5	Looking up an Instance Handle	430
31.14.6	Getting the Key Value for an Instance	430
31.14.7	Instance Memory Management	430
31.14.8	Consequences of Unpurged Dispose Messages	432
31.14.9	Consequences of DataWriters Reclaiming Disposed Instances	433
31.15	Setting DataWriter QoS Policies	433
31.15.1	Configuring QoS Settings when the DataWriter is Created	437
31.15.2	Comparing QoS Values	439
31.15.3	Changing QoS Settings After the DataWriter Has Been Created	439
31.15.4	Using a Topic's QoS to Initialize a DataWriter's QoS	440
31.16	Navigating Relationships Among DDS Entities	442
31.16.1	Finding Matching Subscriptions	442
31.16.2	Finding the Matching Subscription's ParticipantBuiltinTopicData	443
31.16.3	Finding Related DDS Entities	444
31.17	Asserting Liveliness	444
31.18	Turbo Mode and Automatic Throttling for DataWriter Performance—Experimental Features	444
<b>Chapter 32 Reliability Models for Sending Data</b>		
32.1	Best-effort Delivery Model	446
32.2	Reliable Delivery Model	447
32.3	Overview of the Reliable Protocol	448
32.4	Using QoS Policies to Tune the Reliable Protocol	452
32.4.1	Enabling Reliability	453
32.4.2	Tuning Queue Sizes and Other Resource Limits	454
32.4.3	Controlling Queue Depth with the History QoS Policy	461
32.4.4	Controlling Heartbeats and Retries with DataWriterProtocol QoS Policy	462
32.4.5	Avoiding Message Storms with DataReaderProtocol QoS Policy	470
32.4.6	Resending DDS Samples to Late-Joiners with the Durability QoS Policy	470
32.4.7	Use Cases	470
32.5	Auto Throttling for DataWriter Performance—Experimental Feature	483
<b>Chapter 33 Guaranteed Delivery of Data</b>		
33.1	Identifying the Required Consumers of Information	486
33.2	Ensuring Consumer Applications Process the Data Successfully	488
33.3	Ensuring Information is Available to Late-Joining Applications	489

33.4 Use Cases .....	490
33.4.1 Scenario 1: Guaranteed Delivery to a-priori Known Subscribers .....	490
33.4.2 Scenario 2: Surviving a Writer Restart when Delivering DDS Samples to a priori Known Subscribers .....	492
33.4.3 Scenario 3: Delivery Guaranteed by Persistence Service (Store and Forward) to a priori Known Subscribers .....	493
<b>Chapter 34 Sending Large Data</b>	
34.1 Reducing Latency .....	498
34.1.1 Use Cases .....	499
34.1.2 Copies in the Middleware Memory Space .....	500
34.1.3 Choosing between FlatData Language Binding and Zero Copy Transfer over Shared Memory .....	503
34.1.4 FlatData Language Binding .....	503
34.1.5 Zero Copy Transfer Over Shared Memory .....	516
34.2 Reducing Bandwidth Usage .....	524
34.3 Large Data Fragmentation .....	524
34.3.1 Avoiding IP-Level Fragmentation .....	527
34.3.2 Reliable Reliability .....	529
34.3.3 Asynchronous Publishing .....	529
34.3.4 Flow Controllers .....	530
34.3.5 Example .....	530
34.3.6 Fragmentation Statistics .....	532
34.4 FlowControllers (DDS Extension) .....	532
34.4.1 Flow Controller Scheduling Policies .....	534
34.4.2 Managing Fast DataWriters When Using a FlowController .....	535
34.4.3 Token Bucket Properties .....	536
34.4.4 Prioritized DDS Samples .....	538
34.4.5 Creating and Configuring Custom FlowControllers with Property QoS .....	541
34.4.6 Creating and Deleting FlowControllers .....	543
34.4.7 Getting/Setting Default FlowController Properties .....	544
34.4.8 Getting/Setting Properties for a Specific FlowController .....	544
34.4.9 Adding an External Trigger .....	545
34.4.10 Other FlowController Operations .....	545
<b>Chapter 35 Filtering Data</b>	
35.1 Where Filtering is Applied—Publishing vs. Subscribing Side .....	547
35.2 Creating ContentFilteredTopics .....	548
35.2.1 Creating ContentFilteredTopics for Built-in DDS Types .....	550
35.3 Deleting ContentFilteredTopics .....	552
35.4 Using a ContentFilteredTopic .....	552

---

---

35.4.1	Getting the Current Expression Parameters .....	553
35.4.2	Setting an Expression's Filter and Parameters .....	553
35.4.3	Appending a String to an Expression Parameter .....	554
35.4.4	Removing a String from an Expression Parameter .....	554
35.4.5	Getting the Filter Expression .....	554
35.4.6	Getting the Related Topic .....	555
35.4.7	'Narrowing' a ContentFilteredTopic to a TopicDescription .....	555
35.5	SQL Filter Expression Notation .....	555
35.5.1	Example SQL Filter Expressions .....	555
35.5.2	SQL Grammar .....	557
35.5.3	Token Expressions .....	558
35.5.4	Type Compatibility in the Predicate .....	559
35.5.5	SQL Extension: Regular Expression Matching .....	560
35.5.6	Composite Members .....	561
35.5.7	Strings .....	562
35.5.8	Enumerations .....	562
35.5.9	Pointers .....	562
35.5.10	Arrays .....	562
35.5.11	Optional Members .....	563
35.5.12	Sequences .....	564
35.6	STRINGMATCH Filter Expression Notation .....	564
35.6.1	Example STRINGMATCH Filter Expressions .....	565
35.6.2	STRINGMATCH Filter Expression Parameters .....	565
35.7	Character Encoding .....	565
35.8	Unicode Normalization .....	566
35.9	Custom Content Filters .....	567
35.9.1	Filtering on the Writer Side with Custom Filters .....	567
35.9.2	Registering a Custom Filter .....	568
35.9.3	Unregistering a Custom Filter .....	570
35.9.4	Retrieving a ContentFilter .....	571
35.9.5	Compile Function .....	571
35.9.6	Evaluate Function .....	572
35.9.7	Finalize Function .....	572
35.9.8	Writer Attach Function .....	573
35.9.9	Writer Detach Function .....	573
35.9.10	Writer Compile Function .....	573

35.9.11 Writer Evaluate Function .....	574
35.9.12 Writer Return Loan Function .....	574
35.9.13 Writer Finalize Function .....	575
<b>Chapter 36 Multi-Channel DataWriters for High-Performance Filtering</b>	
36.1 Overview of Multi-Channel DataWriters .....	577
36.2 How to Configure a Multi-Channel DataWriter .....	580
36.2.1 Limitations .....	581
36.3 Multi-Channel Configuration on the Reader Side .....	581
36.4 Where Does the Filtering Occur? .....	583
36.4.1 Filtering at the DataWriter .....	583
36.4.2 Filtering at the DataReader .....	583
36.4.3 Filtering on the Network Hardware .....	584
36.5 Fault Tolerance and Redundancy .....	584
36.6 Reliability with Multi-Channel DataWriters .....	585
36.6.1 Reliable Delivery .....	585
36.6.2 Reliable Protocol Considerations .....	586
36.7 Performance Considerations .....	586
36.7.1 Network-Switch Filtering .....	586
36.7.2 DataWriter and DataReader Filtering .....	587
<b>Chapter 37 Collaborative DataWriters (Maintain Global, Ordered Set of Samples)</b>	
37.1 Collaborative DataWriters Use Cases .....	589
37.2 Sample Combination (Synchronization) Process in a DataReader .....	590
37.3 Configuring Collaborative DataWriters .....	591
37.3.1 Associating Virtual GUIDs with DDS Data Samples .....	591
37.3.2 Associating Virtual Sequence Numbers with DDS Data Samples .....	591
37.3.3 Specifying which DataWriters will Deliver DDS Samples to the DataReader from a Logical Data Source	591
37.3.4 Specifying How Long to Wait for a Missing DDS Sample .....	591
37.4 Collaborative DataWriters and Persistence Service .....	592
<b>Part 6: Receiving Data with Connex</b> .....	<b>593</b>
<b>Chapter 38 Overview of Receiving Data</b> .....	<b>594</b>
<b>Chapter 39 Subscribers</b>	
39.1 Creating Subscribers Explicitly vs. Implicitly .....	600
39.2 Creating Subscribers .....	601
39.3 Deleting Subscribers .....	602
39.3.1 Deleting Contained DataReaders .....	603
39.4 Setting Subscriber QosPolicies .....	603

---

39.4.1	Configuring QoS Settings when the Subscriber is Created	604
39.4.2	Comparing QoS Values	606
39.4.3	Changing QoS Settings After Subscriber Has Been Created	606
39.4.4	Getting and Settings Subscriber's Default QoS Profile and Library	607
39.4.5	Getting and Setting Default QoS for DataReaders	608
39.4.6	Subscriber QoS-Related Operations	608
39.5	Beginning and Ending Group-Ordered Access	609
39.6	Setting Up SubscriberListeners	610
39.7	Getting DataReaders with Specific DDS Samples	612
39.8	Finding a Subscriber's Related Entities	612
39.9	Statuses for Subscribers	613
39.9.1	DATA_ON_READERS Status	614
<b>Chapter 40 DataReaders</b>		
40.1	Creating DataReaders	620
40.2	Getting All DataReaders	622
40.3	Deleting DataReaders	622
40.3.1	Deleting Contained ReadConditions	622
40.4	Setting Up DataReaderListeners	622
40.5	Checking DataReader Status and StatusConditions	624
40.6	Waiting for Historical Data	625
40.7	Statuses for DataReaders	626
40.7.1	DATA_AVAILABLE Status	627
40.7.2	DATA_READER_CACHE_STATUS	627
40.7.3	DATA_READER_PROTOCOL_STATUS	630
40.7.4	LIVELINESS_CHANGED Status	634
40.7.5	REQUESTED_DEADLINE_MISSED Status	635
40.7.6	REQUESTED_INCOMPATIBLE_QOS Status	636
40.7.7	SAMPLE_LOST Status	636
40.7.8	SAMPLE_REJECTED Status	640
40.7.9	SUBSCRIPTION_MATCHED Status	642
40.8	Accessing and Managing Instances (Working with Keyed Data Types)	643
40.8.1	Instance States	644
40.8.2	Generation Counts and Ranks	646
40.8.3	Valid Data Flag	648
40.8.4	Looking up an Instance Handle	648
40.8.5	Getting the Key Value for an Instance	648

40.8.6 Instance Resource Limits and Memory Management .....	649
40.8.7 Active State and Minimum State .....	649
40.8.8 Instance Resource Limit QoS Policies .....	651
40.9 Setting DataReader QoS Policies .....	652
40.9.1 Configuring QoS Settings when the DataReader is Created .....	655
40.9.2 Comparing QoS Values .....	657
40.9.3 Changing QoS Settings After the DataReader has been Created .....	657
40.9.4 Using a Topic's QoS to Initialize a DataReader's QoS .....	658
40.10 Navigating Relationships Among Entities .....	660
40.10.1 Finding Matching Publications .....	660
40.10.2 Finding the Matching Publication's ParticipantBuiltinTopicData .....	661
40.10.3 Finding a DataReader's Related Entities .....	661
40.10.4 Looking Up an Instance Handle .....	662
40.10.5 Getting the Key Value for an Instance .....	662
<b>Chapter 41 Using DataReaders to Access Data (Read &amp; Take)</b>	
41.1 Using a Type-Specific DataReader (FooDataReader) .....	663
41.2 Loaning and Returning Data and SampleInfo Sequences .....	664
41.2.1 C, Traditional C++, Java and .NET .....	664
41.2.2 Modern C++ .....	665
41.3 Accessing DDS Data Samples with Read or Take .....	665
41.3.1 Read vs. Take .....	666
41.3.2 General Patterns for Accessing Data .....	668
41.3.3 read_next_sample and take_next_sample .....	669
41.3.4 read_instance and take_instance .....	670
41.3.5 read_next_instance and take_next_instance .....	670
41.3.6 read_w_condition and take_w_condition .....	672
41.3.7 read_instance_w_condition and take_instance_w_condition .....	672
41.3.8 read_next_instance_w_condition and take_next_instance_w_condition .....	673
41.3.9 The select() API (Modern C++ and C#) .....	673
41.4 Acknowledging DDS Samples .....	674
41.5 The Sequence Data Structure .....	675
41.6 The SampleInfo Structure .....	676
41.6.1 Reception Timestamp .....	679
41.6.2 Sample States .....	679
41.6.3 View States .....	680
41.6.4 Instance States .....	680

41.6.5	Generation Counts and Ranks .....	680
41.6.6	Valid Data Flag .....	680
<b>Part 7:</b>	<b>Configuring Connex Using QoS .....</b>	<b>682</b>
<b>Chapter 42</b>	<b>All QoS Policies</b>	
42.1	QoS Requested vs. Offered Compatibility—the RxO Property .....	687
42.2	Special QoS Policy Handling Considerations for C .....	688
<b>Chapter 43</b>	<b>DomainParticipantFactory QoS Policies</b>	
43.1	LOGGING QoS Policy (DDS Extension) .....	690
43.1.1	Example .....	691
43.1.2	Properties .....	691
43.1.3	Related QoS Policies .....	691
43.1.4	Applicable DDS Entities .....	691
43.1.5	System Resource Considerations .....	691
43.2	PROFILE QoS Policy (DDS Extension) .....	691
43.2.1	Example .....	692
43.2.2	Properties .....	693
43.2.3	Related QoS Policies .....	693
43.2.4	Applicable Entities .....	693
43.2.5	System Resource Considerations .....	693
43.3	SYSTEM_RESOURCE_LIMITS QoS Policy (DDS Extension) .....	693
43.3.1	Properties .....	694
43.3.2	Related QoS Policies .....	694
43.3.3	Applicable DDS Entities .....	695
43.3.4	System Resource Considerations .....	695
<b>Chapter 44</b>	<b>DomainParticipant QoS Policies</b>	
44.1	DATABASE QoS Policy (DDS Extension) .....	696
44.1.1	Example .....	698
44.1.2	Properties .....	698
44.1.3	Related QoS Policies .....	698
44.1.4	Applicable DDS Entities .....	698
44.1.5	System Resource Considerations .....	698
44.2	DISCOVERY QoS Policy (DDS Extension) .....	699
44.2.1	Transports Used for Discovery .....	699
44.2.2	Setting the ‘Initial Peers’ List .....	700
44.2.3	Adding and Removing Peers List Entries .....	700
44.2.4	Configuring Multicast Receive Addresses .....	701

---

44.2.5	Meta-Traffic Transport Priority	701
44.2.6	Controlling Acceptance of Unknown Peers	701
44.2.7	Example	702
44.2.8	Properties	703
44.2.9	Related QosPolicies	703
44.2.10	Applicable Entities	703
44.2.11	System Resource Considerations	703
44.3	DISCOVERY_CONFIG QosPolicy (DDS Extension)	703
44.3.1	Resource Limits for Builtin-Topic DataReaders	710
44.3.2	Controlling Purging of Remote Participants	712
44.3.3	Controlling the Reliable Protocol Used by Builtin-Topic DataWriters/DataReaders	713
44.3.4	Example	713
44.3.5	Properties	713
44.3.6	Related QosPolicies	713
44.3.7	Applicable DDS Entities	714
44.3.8	System Resource Considerations	714
44.4	DOMAIN_PARTICIPANT_RESOURCE_LIMITS QosPolicy (DDS Extension)	714
44.4.1	Configuring Resource Limits for Asynchronous DataWriters	719
44.4.2	Configuring Memory Allocation	720
44.4.3	Example	720
44.4.4	Properties	720
44.4.5	Related QosPolicies	721
44.4.6	Applicable DDS Entities	721
44.4.7	System Resource Considerations	721
44.5	EVENT QosPolicy (DDS Extension)	721
44.5.1	Example	722
44.5.2	Properties	723
44.5.3	Related QosPolicies	723
44.5.4	Applicable DDS Entities	723
44.5.5	System Resource Considerations	723
44.6	RECEIVER_POOL QosPolicy (DDS Extension)	723
44.6.1	Example	725
44.6.2	Properties	725
44.6.3	Related QosPolicies	725
44.6.4	Applicable DDS Entities	725
44.6.5	System Resource Considerations	725

44.7 TRANSPORT_BUILTIN QosPolicy (DDS Extension)	725
44.7.1 Example	726
44.7.2 Properties	726
44.7.3 Related QosPolicies	726
44.7.4 Applicable DDS Entities	727
44.7.5 System Resource Considerations	727
44.8 TRANSPORT_MULTICAST_MAPPING QosPolicy (DDS Extension)	727
44.8.1 Formatting Rules for Addresses	728
44.8.2 Example	729
44.8.3 Properties	729
44.8.4 Related QosPolicies	729
44.8.5 Applicable DDS Entities	729
44.8.6 System Resource Considerations	729
44.9 WIRE_PROTOCOL QosPolicy (DDS Extension)	730
44.9.1 Choosing Participant IDs	730
44.9.2 Ports Used for Discovery	732
44.9.3 Controlling How the GUID is Set (rtps_auto_id_kind)	732
44.9.4 Properties	736
44.9.5 Related QosPolicies	736
44.9.6 Applicable DDS Entities	736
44.9.7 System Resource Considerations	736
<b>Chapter 45 Topic QosPolicies</b>	
45.1 TOPIC_DATA QosPolicy	737
45.1.1 Example	738
45.1.2 Properties	738
45.1.3 Related QosPolicies	738
45.1.4 Applicable DDS Entities	738
45.1.5 System Resource Considerations	739
<b>Chapter 46 Publisher/Subscriber QosPolicies</b>	
46.1 ASYNCHRONOUS_PUBLISHER QosPolicy (DDS Extension)	740
46.1.1 Properties	742
46.1.2 Related PropertyQos Policies	742
46.1.3 Related QosPolicies	742
46.1.4 Applicable DDS Entities	743
46.1.5 System Resource Considerations	743
46.2 ENTITYFACTORY QosPolicy	743

46.2.1 Example .....	745
46.2.2 Properties .....	745
46.2.3 Related QosPolicies .....	745
46.2.4 Applicable DDS Entities .....	745
46.2.5 System Resource Considerations .....	746
46.3 EXCLUSIVE_AREA QosPolicy (DDS Extension) .....	746
46.3.1 Example .....	747
46.3.2 Properties .....	748
46.3.3 Related QosPolicies .....	748
46.3.4 Applicable DDS Entities .....	748
46.3.5 System Resource Considerations .....	748
46.4 GROUP_DATA QosPolicy .....	748
46.4.1 Example .....	749
46.4.2 Properties .....	750
46.4.3 Related QosPolicies .....	750
46.4.4 Applicable DDS Entities .....	750
46.4.5 System Resource Considerations .....	751
46.5 PARTITION QosPolicy .....	751
46.5.1 Rules for PARTITION Matching .....	753
46.5.2 Pattern Matching for PARTITION Names .....	754
46.5.3 Example .....	755
46.5.4 Properties .....	757
46.5.5 Related QosPolicies .....	757
46.5.6 Applicable DDS Entities .....	757
46.5.7 System Resource Considerations .....	757
46.5.8 Partition Changes .....	758
46.6 PRESENTATION QosPolicy .....	760
46.6.1 Coherent Access .....	761
46.6.2 Ordered Access .....	762
46.6.3 Example .....	763
46.6.4 Properties .....	765
46.6.5 Related QosPolicies .....	766
46.6.6 Applicable DDS Entities .....	766
46.6.7 System Resource Considerations .....	767

**Chapter 47 DataWriter QosPolicies**

47.1 AVAILABILITY QosPolicy (DDS Extension) .....	769
---------------------------------------------------	-----

---

---

47.1.1 Availability QoS Policy and Collaborative DataWriters .....	770
47.1.2 Availability QoS Policy and Required Subscriptions .....	771
47.1.3 Properties .....	772
47.1.4 Related QoS Policies .....	772
47.1.5 Applicable DDS Entities .....	773
47.1.6 System Resource Considerations .....	773
47.2 BATCH QoS Policy (DDS Extension) .....	773
47.2.1 Synchronous and Asynchronous Flushing .....	775
47.2.2 Batching vs. Coalescing .....	776
47.2.3 Batching and ContentFilteredTopics .....	776
47.2.4 Turbo Mode: Automatically Adjusting the Number of Bytes in a Batch—Experimental Feature .....	776
47.2.5 Performance Considerations .....	777
47.2.6 Maximum Transport Datagram Size .....	777
47.2.7 Bandwidth Considerations .....	777
47.2.8 Properties .....	778
47.2.9 Related QoS Policies .....	778
47.2.10 Applicable DDS Entities .....	779
47.2.11 System Resource Considerations .....	779
47.3 DATA_REPRESENTATION QoS Policy .....	780
47.3.1 Data Representation .....	781
47.3.2 Data Compression .....	782
47.3.3 Properties .....	786
47.3.4 Applicable Entities .....	787
47.4 DATATAG QoS Policy .....	787
47.4.1 Properties .....	788
47.4.2 Related QoS Policies .....	788
47.4.3 Applicable Entities .....	788
47.4.4 System Resource Considerations .....	788
47.5 DATA_WRITER_PROTOCOL QoS Policy (DDS Extension) .....	788
47.5.1 High and Low Watermarks .....	793
47.5.2 Normal, Fast, and Late-Joiner Heartbeat Periods .....	794
47.5.3 Disabling Positive Acknowledgements .....	795
47.5.4 Configuring the Send Window Size .....	796
47.5.5 Propagating Serialized Keys with Disposed-Instance Notifications .....	796
47.5.6 Virtual Heartbeats .....	797
47.5.7 Resending Over Multicast .....	798

47.5.8 Example .....	798
47.5.9 Properties .....	799
47.5.10 Related QosPolicies .....	799
47.5.11 Applicable DDS Entities .....	799
47.5.12 System Resource Considerations .....	800
47.6 DATA_WRITER_RESOURCE_LIMITS QosPolicy (DDS Extension) .....	800
47.6.1 Configuring DataWriter Instance Replacement .....	802
47.6.2 Example .....	803
47.6.3 Properties .....	803
47.6.4 Related QosPolicies .....	803
47.6.5 Applicable DDS Entities .....	804
47.6.6 System Resource Considerations .....	804
47.7 DEADLINE QosPolicy .....	804
47.7.1 Example .....	805
47.7.2 Properties .....	805
47.7.3 Related QosPolicies .....	806
47.7.4 Applicable DDS Entities .....	806
47.7.5 System Resource Considerations .....	806
47.8 DESTINATION_ORDER QosPolicy .....	806
47.8.1 Properties .....	809
47.8.2 Related QosPolicies .....	809
47.8.3 Applicable DDS Entities .....	809
47.8.4 System Resource Considerations .....	809
47.9 DURABILITY QosPolicy .....	809
47.9.1 Example .....	813
47.9.2 Properties .....	813
47.9.3 Related QosPolicies .....	813
47.9.4 Applicable Entities .....	814
47.9.5 System Resource Considerations .....	814
47.10 DURABILITY_SERVICE QosPolicy .....	814
47.10.1 Properties .....	816
47.10.2 Related QosPolicies .....	816
47.10.3 Applicable Entities .....	816
47.10.4 System Resource Considerations .....	816
47.11 ENTITY_NAME QosPolicy (DDS Extension) .....	817
47.11.1 Properties .....	818

---

---

47.11.2	Related QosPolicies .....	818
47.11.3	Applicable Entities .....	818
47.11.4	System Resource Considerations .....	818
47.12	HISTORY QosPolicy .....	818
47.12.1	Example .....	821
47.12.2	Properties .....	822
47.12.3	Related QosPolicies .....	823
47.12.4	Applicable Entities .....	823
47.12.5	System Resource Considerations .....	823
47.13	LATENCYBUDGET QoS Policy .....	823
47.13.1	Applicable Entities .....	824
47.14	LIFESPAN QoS Policy .....	824
47.14.1	Properties .....	825
47.14.2	Related QoS Policies .....	825
47.14.3	Applicable Entities .....	825
47.14.4	System Resource Considerations .....	825
47.15	LIVELINESS QosPolicy .....	825
47.15.1	Timing Considerations for MANUAL_BY_PARTICIPANT .....	828
47.15.2	Example .....	829
47.15.3	Properties .....	829
47.15.4	Related QosPolicies .....	830
47.15.5	Applicable Entities .....	830
47.15.6	System Resource Considerations .....	830
47.16	MULTI_CHANNEL QosPolicy (DDS Extension) .....	830
47.16.1	Example .....	832
47.16.2	Properties .....	832
47.16.3	Related Qos Policies .....	833
47.16.4	Applicable Entities .....	833
47.16.5	System Resource Considerations .....	833
47.17	OWNERSHIP QosPolicy .....	833
47.17.1	How Connext Selects which DataWriter is the Exclusive Owner .....	834
47.17.2	Example .....	835
47.17.3	Properties .....	836
47.17.4	Related QosPolicies .....	836
47.17.5	Applicable Entities .....	836
47.17.6	System Resource Considerations .....	836

---

47.18 OWNERSHIP_STRENGTH QosPolicy .....	836
47.18.1 Example .....	837
47.18.2 Properties .....	837
47.18.3 Related QosPolicies .....	837
47.18.4 Applicable Entities .....	837
47.18.5 System Resource Considerations .....	837
47.19 PROPERTY QosPolicy (DDS Extension) .....	837
47.19.1 Property Validation .....	840
47.19.2 Properties .....	842
47.19.3 Related QosPolicies .....	842
47.19.4 Applicable Entities .....	842
47.19.5 System Resource Considerations .....	843
47.20 PUBLISH_MODE QosPolicy (DDS Extension) .....	843
47.20.1 Properties .....	845
47.20.2 Related QosPolicies .....	845
47.20.3 Applicable Entities .....	845
47.20.4 System Resource Considerations .....	845
47.21 RELIABILITY QosPolicy .....	845
47.21.1 Example .....	848
47.21.2 Properties .....	848
47.21.3 Related QosPolicies .....	849
47.21.4 Applicable Entities .....	849
47.21.5 System Resource Considerations .....	850
47.22 RESOURCE_LIMITS QosPolicy .....	850
47.22.1 Configuring Resource Limits for Asynchronous DataWriters .....	852
47.22.2 Example .....	852
47.22.3 Properties .....	852
47.22.4 Related QosPolicies .....	852
47.22.5 Applicable Entities .....	853
47.22.6 System Resource Considerations .....	853
47.23 SERVICE QosPolicy (DDS Extension) .....	853
47.23.1 Properties .....	853
47.23.2 Related QosPolicies .....	854
47.23.3 Applicable Entities .....	854
47.23.4 System Resource Considerations .....	854
47.24 TOPIC_QUERY_DISPATCH_QosPolicy (DDS Extension) .....	854

47.30.4	Applicable Entities .....	866
47.30.5	System Resource Considerations .....	866
47.31	WRITER_DATA_LIFECYCLE QoS Policy .....	866
47.31.1	Unregistering vs. Disposing .....	867
47.31.2	Autodisposing Unregistered Instances .....	868
47.31.3	Properties .....	868
47.31.4	Related QoS Policies .....	868
47.31.5	Applicable Entities .....	868
47.31.6	System Resource Considerations .....	869
<b>Chapter 48 DataReader QoS Policies</b>		
48.1	DATA_READER_PROTOCOL QoS Policy (DDS Extension) .....	871
48.1.1	Receive Window Size .....	874
48.1.2	Round-Trip Time For Filtering Redundant NACKs .....	875
48.1.3	Example .....	875
48.1.4	Properties .....	876
48.1.5	Related QoS Policies .....	876
48.1.6	Applicable DDS Entities .....	876
48.1.7	System Resource Considerations .....	876
48.2	DATA_READER_RESOURCE_LIMITS QoS Policy (DDS Extension) .....	876
48.2.1	max_total_instances and max_instances .....	881
48.2.2	keep_minimum_state_for_instances .....	882
48.2.3	Configuring DataReader Instance Replacement .....	882
48.2.4	Example .....	884
48.2.5	Properties .....	885
48.2.6	Related QoS Policies .....	885
48.2.7	Applicable DDS Entities .....	885
48.2.8	System Resource Considerations .....	885
48.3	READER_DATA_LIFECYCLE QoS Policy .....	885
48.3.1	Properties .....	887
48.3.2	Related QoS Policies .....	887
48.3.3	Applicable DDS Entities .....	887
48.3.4	System Resource Considerations .....	888
48.4	TIME_BASED_FILTER QoS Policy .....	888
48.4.1	Example .....	890
48.4.2	Properties .....	890
48.4.3	Related QoS Policies .....	890

48.4.4	Applicable DDS Entities .....	890
48.4.5	System Resource Considerations .....	890
48.5	TRANSPORT_MULTICAST QosPolicy (DDS Extension) .....	891
48.5.1	Example .....	893
48.5.2	Properties .....	893
48.5.3	Related QosPolicies .....	893
48.5.4	Applicable DDS Entities .....	894
48.5.5	System Resource Considerations .....	894
48.6	TYPE_CONSISTENCY_ENFORCEMENT QosPolicy .....	894
48.6.1	Values for TypeConsistencyKind .....	897
48.6.2	Prevent Type Widening .....	898
48.6.3	Properties .....	899
48.6.4	Related QoS Policies .....	899
48.6.5	Applicable Entities .....	899
48.6.6	System Resource Considerations .....	899
<b>Chapter 49 Configuring Qos Programmatically</b>		
49.1	Changing the QoS Defaults Used to Create DDS Entities: <code>set_default_*_qos()</code> .....	901
49.2	Setting QoS During Entity Creation .....	902
49.3	Changing the QoS for an Existing Entity .....	903
49.4	Default QoS Values .....	903
<b>Chapter 50 Configuring QoS with XML</b>		
50.1	QoS Libraries .....	905
50.2	QoS Profiles .....	906
50.2.1	Built-in QoS Profiles .....	907
50.2.2	Overwriting Default QoS Values .....	909
50.2.3	QoS Profile Inheritance and Composition .....	910
50.2.4	Topic Filters .....	926
50.2.5	QoS Profiles with a Single QoS .....	930
50.3	Example XML File .....	930
50.4	Tags for Configuring QoS with XML .....	931
50.4.1	QosPolicies .....	932
50.4.2	Sequences .....	932
50.4.3	Arrays .....	935
50.4.4	Enumeration Values .....	936
50.4.5	Time Values (Durations) .....	936
50.4.6	Transport Properties .....	936

50.4.7 Thread Settings .....	939
50.4.8 Entity Names .....	939
50.5 How to Load XML-Specified QoS Settings .....	939
50.5.1 Loading, Reloading and Unloading Profiles .....	941
50.6 XML File Syntax .....	942
50.6.1 Using Environment Variables in XML .....	943
50.6.2 Using Special Characters in XML .....	944
50.6.3 Specifying Fully Qualified Names in XML .....	944
50.7 XML String Syntax .....	945
50.8 URL Groups (Loading Redundant Locations) .....	945
50.9 How the XML is Validated .....	946
50.9.1 Validation at Run-Time .....	946
50.9.2 XML File Validation During Editing .....	947
50.9.3 Skipping Element Validation: the <code>must_interpret</code> Attribute .....	948
50.10 Using QoS Profiles in Your Connex Application .....	949
50.10.1 Retrieving a List of Available Libraries .....	952
50.10.2 Retrieving a List of Available QoS Profiles .....	952
50.11 Configuring Logging Via XML .....	953
<b>Part 8: Working with Transports in Connex</b> .....	<b>954</b>
<b>Chapter 51 UDPv4, UDPv6, and Shared Memory Transport Plugins</b>	
51.1 Builtin Transport Plugins .....	955
51.2 Extension Transport Plugins .....	956
51.3 The <code>NDDSTransportSupport</code> Class .....	957
51.4 Explicitly Creating Builtin Transport Plugin Instances .....	958
51.5 Setting Builtin Transport Properties of Default Transport Instance— <code>get/set_builtin_transport_properties()</code> .....	959
51.6 Setting Builtin Transport Properties with the <code>PropertyQosPolicy</code> .....	960
51.6.1 Setting the Maximum Gather-Send Buffer Count for UDP Transports .....	977
51.6.2 Formatting Rules for IPv6 ‘Allow’ and ‘Deny’ Address Lists .....	978
51.7 Installing Additional Builtin Transport Plugins with <code>register_transport()</code> .....	979
51.7.1 Transport Lifecycles .....	980
51.7.2 Transport Aliases .....	981
51.7.3 Transport Network Addresses .....	982
51.8 Installing Additional Builtin Transport Plugins with <code>PropertyQosPolicy</code> .....	982
51.9 Other Transport Support Operations .....	983
51.9.1 Adding a Send Route .....	983
51.9.2 Adding a Receive Route .....	984

---

51.9.3 Looking Up a Transport Plugin .....	985
<b>Chapter 52 RTI Real-Time WAN Transport</b>	
52.1 Introduction to Real-Time WAN Transport .....	986
52.2 Key Terms .....	987
52.2.1 Basic Terms .....	987
52.2.2 IP Address Types .....	987
52.2.3 Locators .....	988
52.2.4 WAN Ecosystem .....	988
52.3 Transport Capabilities .....	988
52.3.1 NAT Traversal .....	988
52.3.2 NAT Kinds .....	989
52.3.3 Identifying the NAT Type .....	991
52.3.4 NAT Bindings .....	992
52.3.5 NAT Bindings Expiration .....	993
52.3.6 NAT Hairpinning .....	994
52.3.7 IP Mobility .....	994
52.4 Communication Scenarios .....	995
52.4.1 Peer-to-Peer Communication between Internal Participant and External Participant .....	995
52.4.2 Peer-to-Peer Communication between Two Internal Participants .....	998
52.5 Deployment Scenarios .....	1001
52.5.1 Edge-to-Data Center Deployment Scenario .....	1001
52.5.2 Relayed Edge-to-Edge Deployment Scenario .....	1006
52.5.3 Peer-to-Peer, Edge-to-Edge Deployment Scenario .....	1010
52.6 Enabling Real-Time WAN Transport .....	1013
52.6.1 Dynamically Loading the Real-Time WAN Transport .....	1013
52.6.2 Linking the Real-Time WAN Transport against your Application .....	1013
52.7 Transport Initial Peers .....	1014
52.8 Transport Configuration .....	1015
52.8.1 Setting Real-Time WAN Transport Properties .....	1016
52.8.2 Managing UDP Ports Used for Communication .....	1025
52.8.3 Disabling IP Fragmentation for Real-Time WAN Transport .....	1030
52.9 Security .....	1032
52.10 Advanced Concepts .....	1032
52.10.1 Transport Locators .....	1032
52.10.2 Binding Ping Messages .....	1034
52.10.3 Communication Establishment Protocol for Peer-to-Peer Communication with Participants behind Cone NATs .....	1034

52.10.4	Communication Establishment Protocol for Peer-to-Peer Communication with a Participant that has a Public Address .....	1037
52.11	Transport Debugging .....	1039
52.11.1	Debugging Peer-to-Peer Communication with a Participant that has a Public Address .....	1039
52.11.2	Peer-to-Peer Communication with Participants behind Cone NATs .....	1042
52.12	Tools Integration .....	1045
52.13	Troubleshooting Real-Time WAN Transport .....	1046
52.13.1	Communication Stops Working after Application Transitions to Different Network .....	1046
52.13.2	Communication not Established after Changing Cloud Discovery Service <receiver_port> .....	1047
52.13.3	Communication not Established even though Transport Settings are Set Correctly .....	1048
52.13.4	Slow Discovery using Cloud Discovery Service .....	1049
<b>Chapter 53 RTI TCP Transport</b>		
53.1	TCP Communication Scenarios .....	1051
53.1.1	Communication Within a Single LAN .....	1051
53.1.2	Symmetric Communication Across NATs .....	1052
53.1.3	Asymmetric Communication Across NATs .....	1053
53.2	Configuring the TCP Transport .....	1055
53.2.1	Choosing a Transport Mode .....	1055
53.2.2	Explicitly Instantiating the TCP Transport Plugin .....	1056
53.2.3	Configuring the TCP Transport with the Property QosPolicy .....	1058
53.2.4	Setting the Initial Peers .....	1061
53.2.5	RTPS Locator Format .....	1062
53.2.6	Support for External Hardware Load Balancers in TCP Transport Plugin .....	1063
53.2.7	TCP/TLS Transport Properties .....	1065
<b>Part 9: Debugging and Monitoring Connex Applications</b> .....		<b>1085</b>
<b>Chapter 54 Logging</b>		
54.1	What Version am I Running? .....	1086
54.1.1	Finding Version Information in Revision Files .....	1086
54.1.2	Finding Version Information on Windows or Linux Systems .....	1087
54.1.3	Finding Version Information Programmatically .....	1087
54.2	Configuring Connex Logging .....	1089
54.2.1	Format of Logged Messages .....	1092
54.2.2	Customizing the Handling of Generated Log Messages .....	1099
54.3	Configuring Logging via XML .....	1099
54.4	Setting Warnings for Operation Delays .....	1101
54.5	Logging a Backtrace for Failures .....	1102
54.6	RTI Distributed Logger .....	1103

---

54.6.1 Using Distributed Logger in a Connext Application .....	1104
54.6.2 Enabling Distributed Logger in RTI Services .....	1112
<b>Chapter 55 Troubleshooting Discovery .....</b>	<b>1117</b>
<b>Chapter 56 Heap Memory Monitoring .....</b>	<b>1120</b>
<b>Chapter 57 Discovery Snapshots</b>	
57.1 Viewing the Discovery Status .....	1121
57.2 Using Snapshots to Debug the Discovery Process .....	1123
<b>Chapter 58 Network Capture</b>	
58.1 Capturing Shared Memory Traffic .....	1125
<b>Chapter 59 RTI Monitoring Library</b>	
59.1 Enabling Monitoring in Your Application .....	1127
59.1.1 Method 1—Change the Participant QoS to Automatically Load the Dynamic Monitoring Library .....	1128
59.1.2 Method 2—Change the Participant QoS to Specify the Monitoring Library Create Function Pointer and Explicitly Load the Monitoring Library .....	1129
59.2 How Does Monitoring Work? .....	1134
59.3 What Monitoring Topics are Published? .....	1134
59.4 Enabling Support for Large Type-Code (Optional) .....	1135
59.5 Configuring Monitoring Library .....	1136
59.6 Troubleshooting Monitoring .....	1140
59.6.1 Enabling Support for Large Type-Code (Optional) .....	1140
59.6.2 Buffer Allocation Error .....	1140
<b>Part 10: Alternative Communication Models .....</b>	<b>1141</b>
<b>Chapter 60 Topic Queries</b>	
60.1 Reading TopicQuery Samples .....	1143
60.2 Debugging Topic Queries .....	1143
60.2.1 The Built-in ServiceRequest DataReader .....	1143
60.2.2 The on_service_request_accepted() DataWriter Listener Callback .....	1144
60.3 System Resource Considerations .....	1144
60.3.1 Publishing Application .....	1144
60.3.2 Subscribing Application .....	1144
<b>Chapter 61 Request-Reply</b>	
61.1 Introduction to the Request-Reply Communication Pattern .....	1146
61.1.1 The Request-Reply Pattern .....	1147
61.1.2 Single-Request, Multiple-Replies .....	1149
61.1.3 Multiple Repliers .....	1150
61.1.4 Combining Request-Reply and Publish-Subscribe .....	1151
61.2 Using the Request-Reply Communication Pattern .....	1151

61.2.1 Requesters .....	1152
61.2.2 Repliers .....	1160
61.2.3 SimpleRepliers .....	1166
61.2.4 Accessing Underlying DataWriters and DataReaders .....	1168
<b>Chapter 62 Remote Procedure Calls (RPC)—Experimental Feature</b>	
62.1 RPC Service .....	1171
62.1.1 Creating a Service .....	1172
62.1.2 Setting the Server Parameters .....	1173
62.1.3 Summary of Server Operations .....	1173
62.1.4 Running and Closing the Server .....	1174
62.1.5 Setting the Service Parameters .....	1174
62.2 RPC Client .....	1175
62.2.1 Creating a Client .....	1175
62.2.2 Setting the Client Parameters .....	1176
62.2.3 Summary of Client Operations .....	1176
62.2.4 Waiting for Services .....	1177
62.2.5 Making Remote Function Calls .....	1177
62.3 Accessing Underlying DataWriters and DataReaders .....	1178
62.4 Generating RPC Code from IDL using RTI Code Generator .....	1179
<b>Part 11: Connex Thread Model</b> .....	<b>1180</b>
<b>Chapter 63 Overview</b> .....	<b>1181</b>
<b>Chapter 64 Database Thread</b> .....	<b>1183</b>
<b>Chapter 65 Event Thread</b> .....	<b>1185</b>
<b>Chapter 66 Receive Threads</b> .....	<b>1187</b>
<b>Chapter 67 Exclusive Areas, RTI Connex Threads, and User Listeners</b> .....	<b>1190</b>
<b>Chapter 68 Controlling CPU Core Affinity for RTI Threads</b> .....	<b>1191</b>
<b>Chapter 69 Configuring Thread Settings with XML</b> .....	<b>1192</b>
<b>Chapter 70 User-Managed Threads</b> .....	<b>1194</b>
<b>Chapter 71 Unregistering Threads</b> .....	<b>1195</b>
<b>Chapter 72 Identifying Threads Used by Connex</b>	
72.1 Checking Thread Names at the OS Level .....	1196
72.2 Checking Thread Names from the Call Stack .....	1202
72.3 Checking Thread Names Using the Worker's Name .....	1203
<b>Part 12: RTI Persistence Service</b> .....	<b>1205</b>
<b>Chapter 73 Introduction to RTI Persistence Service</b> .....	<b>1206</b>
<b>Chapter 74 Configuring Persistence Service</b>	

74.1 How to Load the Persistence Service XML Configuration .....	1208
74.2 XML Configuration File .....	1209
74.2.1 Configuration File Syntax .....	1210
74.2.2 XML Validation .....	1211
74.3 QoS Configuration .....	1212
74.4 Configuring the Persistence Service Application .....	1213
74.5 Configuring Remote Administration .....	1215
74.6 Configuring Persistent Storage .....	1216
74.7 Configuring Participants .....	1218
74.8 Creating Persistence Groups .....	1220
74.8.1 QoSs .....	1223
74.8.2 DurabilityService QoS Policy .....	1224
74.8.3 Sharing a Publisher/Subscriber .....	1225
74.8.4 Memory Management .....	1225
74.9 Configuring Durable Subscriptions in Persistence Service .....	1226
74.9.1 DDS Sample Memory Management With Durable Subscriptions .....	1227
74.10 Synchronizing of Persistence Service Instances .....	1228
74.11 Enabling RTI Distributed Logger in Persistence Service .....	1228
74.12 Enabling RTI Monitoring Library in Persistence Service .....	1229
74.13 Support for Extensible Types .....	1230
74.13.1 TypeConsistencyEnforcementQosPolicy Integration .....	1230
74.13.2 DataRepresentationQosPolicy Integration .....	1231
74.14 TCP Transport Support in Persistence Service .....	1232
<b>Chapter 75 Running RTI Persistence Service</b>	
75.1 Starting Persistence Service .....	1233
75.2 Stopping Persistence Service .....	1235
<b>Chapter 76 Administering Persistence Service from a Remote Location</b>	
76.1 Enabling Remote Administration .....	1236
76.2 Remote Commands .....	1237
76.2.1 start .....	1237
76.2.2 stop .....	1237
76.2.3 shutdown .....	1237
76.2.4 status .....	1238
76.3 Accessing Persistence Service from a Connex Application .....	1238
<b>Chapter 77 Advanced Persistence Service Scenarios</b>	
77.1 Scenario: Load-balanced Persistence Services .....	1242

---

---

77.2 Scenario: Delegated Reliability .....	1244
77.3 Scenario: Slow Consumer .....	1245

# About this Document

## Paths Mentioned in Documentation

The documentation refers to:

- **<NDDSHOME>**

This refers to the installation directory for *RTI® Connexxt®*. The default installation paths are:

- macOS® systems:  
**/Applications/rti\_connexxt\_dds-7.0.0**
- Linux systems, non-*root* user:  
**/home/<your user name>/rti\_connexxt\_dds-7.0.0**
- Linux systems, *root* user:  
**/opt/rti\_connexxt\_dds-7.0.0**
- Windows® systems, user without Administrator privileges:  
**<your home directory>\rti\_connexxt\_dds-7.0.0**
- Windows systems, user with Administrator privileges:  
**C:\Program Files\rti\_connexxt\_dds-7.0.0**

You may also see **\$NDDSHOME** or **%NDDSHOME%**, which refers to an environment variable set to the installation path.

Wherever you see **<NDDSHOME>** used in a path, replace it with your installation path.

**Note for Windows Users:** When using a command prompt to enter a command that includes the path **C:\Program Files** (or any directory name that has a space), enclose the path in quotation marks. For example:

```
"C:\Program Files\rti_connex-dds-7.0.0\bin\rtiddsgen"
```

Or if you have defined the **NDDSHOME** environment variable:

```
"%NDDSHOME%\bin\rtiddsgen"
```

- *<path to examples>*

By default, examples are copied into your home directory the first time you run *RTI Launcher* or any script in **<NDDSHOME>/bin**. This document refers to the location of the copied examples as *<path to examples>*.

Wherever you see *<path to examples>*, replace it with the appropriate path.

Default path to the examples:

- macOS systems: **/Users/<your user name>/rti\_workspace/7.0.0/examples**
- Linux systems: **/home/<your user name>/rti\_workspace/7.0.0/examples**
- Windows systems: **<your Windows documents folder>\rti\_workspace\7.0.0\examples**

Where 'your Windows documents folder' depends on your version of Windows. For example, on Windows 10, the folder is **C:\Users\<your user name>\Documents**.

Note: You can specify a different location for **rti\_workspace**. You can also specify that you do not want the examples copied to the workspace. For details, see *Controlling Location for RTI Workspace and Copying of Examples* in the *RTI Connex Installation Guide*.

## Programming Language Conventions

The terminology and example code in this manual assume you are using Traditional C++ without namespace support.

C, Modern C++, C#, and Java APIs are also available; they are fully described in the API Reference HTML documentation. (Note: the Modern C++ API is not available for all platforms, check the [RTI Connex Core Libraries Platform Notes](#) to see if it is available for your platform.)

Namespace support in Traditional C++, and C# is also available; see the API Reference HTML documentation (from the **Modules** page, select **Using DDS:: Namespace**) for details. In the Modern C++ API all types, constants and functions are always in namespaces.

### Traditional vs. Modern C++

*Connex* provides two different C++ APIs, which we refer to as the "Traditional C++" and "Modern C++" APIs. They provide substantially different programming paradigms and patterns. The Traditional

API could be considered as simply "C with classes," while the Modern API incorporates modern C++ techniques, most notably:

- Generic programming
- Integration with the standard library
- Automatic object lifecycle management, providing full value types and reference types
- C++11 support, such as move operations, initializer lists, and support for range for-loops.

These different programming styles make the Modern C++ API differ significantly with respect to the other language APIs in several aspects; to name a few:

- [17.3 Creating User Data Types with IDL on page 153](#)
- [17.8 Interacting Dynamically with User Data Types on page 236](#)
- [17.9 Working with DDS Data Samples on page 240](#)
- [15.1 Creating and Deleting DDS Entities on page 33](#)
- [Chapter 41 Using DataReaders to Access Data \(Read & Take\) on page 663](#)
- QoS policies and QoS management
- Naming conventions

This manual points out these kinds of differences whenever they are substantial.

## Extensions to the DDS Standard

*Connex*t implements the DDS Standard published by the OMG. It also includes features that are extensions to DDS. These include additional Quality of Service parameters, function calls, structure fields, etc.

Extensions also include product-specific APIs that complement the DDS API. These include APIs to create and use transport plug-ins, and APIs to control the verbosity and logging capabilities. These APIs are prefixed with NDDS, such as **NDDSTransportSupport::register\_transport()**.

## Environment Variables

*Connex*t documentation refers to path names that have been customized during installation. NDDSHOME refers to the installation directory of *Connex*t.

## Names of Supported Platforms

*Connex*t runs on several different target platforms. To support this vast array of platforms, *Connex*t separates the executable, library, and object files for each platform into individual directories.

Each platform name has four parts: hardware architecture, operating system, operating system version and compiler. For example, **x64Linux2.6gcc4.4.5** is the directory that contains files specific to Linux® version 2.6 for the x64 Intel processor, compiled with gcc version 4.4.5.

For a full list of supported platforms, see the [Supported Platforms for Compiler-Dependent Products, in the RTI Connex Core Libraries Release Notes](#).

## **Additional Resources**

The details of each API (such as function parameters, return values, etc.) and examples are in the API Reference HTML documentation. In case of discrepancies between the information in this document and the API Reference HTML documentation, the latter should be considered more up-to-date.

# Part 1: Connex Overview

*RTI® Connex®* solutions provide a flexible connectivity software framework for integrating data sources of all types. At its core is the world's leading ultra-high performance, distributed networking *Databus*. It connects data within applications as well as across devices, systems and networks. *Connex* also delivers large data sets with microsecond performance and granular quality-of-service control. *Connex* is a standards-based, open architecture that connects devices from deeply embedded real-time platforms to enterprise servers across a variety of networks. *Connex* simplifies application development, deployment and maintenance and provides fast, predictable distribution of time-critical data over a variety of transport networks.

With *Connex*, you can:

- Perform complex one-to-many and many-to-many network communications.
- Customize application operation to meet various real-time, reliability, and quality-of-service goals.
- Provide application-transparent fault tolerance and application robustness.
- Use a variety of transports.

This section introduces the general concepts behind data-centric publish-subscribe communications and describes how *Connex's* feature-set addresses the needs of real-time systems.

# Chapter 1 What is Connex?

*Connex* is a software connectivity framework for real-time distributed applications. It provides the communications service programmers need to distribute time-critical data between embedded and/or enterprise devices or nodes. *Connex* uses the publish-subscribe communications model to make data distribution efficient and robust.

*Connex* implements the Data-Centric Publish-Subscribe (DCPS) API within the OMG's Data Distribution Service (DDS) for Real-Time Systems. DDS is the first standard developed for the needs of real-time systems. DCPS provides an efficient way to transfer data in a distributed system.

With *Connex*, systems designers and programmers start with a fault-tolerant and flexible communications infrastructure that will work over a wide variety of computer hardware, operating systems, languages, and networking transport protocols. *Connex* is highly configurable so programmers can adapt it to meet the application's specific communication requirements.

## Chapter 2 Features of Connex

*Connex* supports mechanisms that go beyond the basic publish-subscribe model. The key benefit is that applications that use *Connex* for their communications are entirely decoupled. Very little of their design time has to be spent on how to handle their mutual interactions. In particular, the applications never need information about the other participating applications, including their existence or locations. *Connex* automatically handles all aspects of message delivery, without requiring any intervention from the user applications, including:

- determining who should receive the messages,
- where recipients are located,
- what happens if messages cannot be delivered.

This is made possible by how *Connex* allows the user to specify Quality of Service (QoS) parameters as a way to configure automatic-discovery mechanisms and specify the behavior used when sending and receiving messages. The mechanisms are configured up-front and require no further effort on the user's part. By exchanging messages in a completely anonymous manner, *Connex* greatly simplifies distributed application design and encourages modular, well-structured programs.

Furthermore, *Connex* includes the following features, which are designed to meet the needs of distributed real-time applications:

- **Data-centric publish-subscribe communications:** Simplifies distributed application programming and provides time-critical data flow with minimal latency.
  - Clear semantics for managing multiple sources of the same data.
  - Efficient data transfer, customizable Quality of Service, and error notification.
  - Guaranteed periodic samples, with maximum rate set by subscriptions.
  - Notification by a callback routine on data arrival to minimize latency.

- Notification when data does not arrive by an expected deadline.
- Ability to send the same message to multiple computers efficiently.
- **User-definable data types:** Enables you to tailor the format of the information being sent to each application.
- **Reliable messaging:** Enables subscribing applications to specify reliable delivery of samples.
- **Multiple Communication Networks:** Multiple independent communication networks (DDS *domains*), each using *Connex*, can be used over the same physical network. Applications are only able to participate in the DDS domains to which they belong. Individual applications can be configured to participate in multiple DDS domains.
- **Symmetric architecture:** Makes your application robust:
  - No central server or privileged nodes, so the system is robust to node failures.
  - Subscriptions and publications can be dynamically added and removed from the system at any time.
- **Pluggable Transports Framework:** Includes the ability to define new transport plug-ins and run over them. *Connex* comes with a standard UDP/IP pluggable transport and a shared memory transport. It can be configured to operate over a variety of transport mechanisms, including back-planes, switched fabrics, and new networking technologies.
- **Multiple Built-in Transports:** Includes UDP/IP and shared memory transports.
- **Multi-language support:** Includes APIs for the C, C++ (Traditional and Modern APIs), C#, and Java™ programming languages.
- **Multi-platform support:** Includes support for flavors of UNIX®, real-time operating systems, and Windows®. (Consult the [RTI Connex Core Libraries Platform Notes](#) to see which platforms are supported in this release.)
- **Compliance with Standards:**
  - API complies with the DCPS layer of the OMG's DDS specification.
  - Data types comply with OMG Interface Definition Language™ (IDL).
  - Data packet format complies with the International Engineering Consortium's (IEC's) publicly available specification for the RTPS wire protocol.

# Chapter 3 Connex Communication Model

This section describes the formal communications model used by *Connex*: the Data-Centric Publish-Subscribe (DCPS) standard. DCPS is a formalization (through a standardized API) and extension of the publish-subscribe communications model presented in [Chapter 4 Network Communications Models on page 7](#).

DCPS is the portion of the OMG DDS (Data Distribution Service) Standard that addresses data-centric publish-subscribe communications. The DDS standard defines a language-independent model of publish-subscribe communications that has standardized mappings into various implementation languages. *Connex* offers C, Traditional C++, Modern C++, C#, and Java versions of the publish-subscribe API.

The publish-subscribe approach to distributed communications is a generic mechanism that can be employed by many different types of applications. The communication model described in this chapter extends the publish-subscribe model to address the specific needs of real-time, data-critical applications. As you'll see, it provides several mechanisms that allow application developers to control how communications works and how the middleware handles resource limitations and error conditions.

The “data-centric” portion of the model describes the fundamental concept supported by the design of the API. In data-centric communications, the focus is on the distribution of *data* between communicating applications. A data-centric system is comprised of data publishers and data subscribers. The communications are based on passing data of known types in named streams from publishers to subscribers.

In contrast, in object-centric communications the fundamental concept is the *interface* between the applications. An interface is comprised of a set of methods of known types (number and types of method arguments). An object-centric system is comprised of interface servers and interface clients, and communications are based on clients invoking methods on named interfaces that are serviced by the corresponding server.

Data and object-centric communications are complementary paradigms in a distributed system. Applications may require both. However, real-time communications often fit a data-centric model more naturally.

Data-centric publish-subscribe, and specifically the *Connex* implementation, is well suited for real-time applications. For instance, real-time applications often require the following features:

- **Efficiency**

Real-time systems require efficient data collection and delivery. Only minimal delays should be introduced into the critical data-transfer path. Publish-subscribe is more efficient than client-server in both latency and bandwidth for periodic data exchange.

Publish-subscribe greatly reduces the overhead required to send data over the network compared to a client-server architecture. Occasional subscription requests, at low bandwidth, replace numerous high-bandwidth client requests. Latency is also reduced, since the outgoing request message time is eliminated. As soon as a new DDS sample becomes available, it is sent to the corresponding subscriptions.

- **Determinism**

Real-time applications often care about the determinism of delivering periodic data as well as the latency of delivering event data. Once buffers are introduced into a data stream to support reliable connections, new data may be held undelivered for an unpredictable amount of time while waiting for confirmation that old data was received.

Since publish-subscribe does not inherently require reliable connections, implementations, like *Connex*, can provide configurable trade-offs between the deterministic delivery of new data and the reliable delivery of all data.

- **Flexible delivery bandwidth**

Typical real-time systems include both real-time and non-real-time nodes. The bandwidth requirements for these nodes—even for the same data—are quite different. For example, an application may be sending DDS samples faster than a non-real-time application is capable of handling. However, a real-time application may want the same data as fast as it is produced.

*Connex* allows subscribers to the same data to set individual limits on how fast data should be delivered to each subscriber. This is similar to how some people get a newspaper every day while others can subscribe to only the Sunday paper.

- **Thread awareness**

Real-time communications must work without slowing the thread that sends DDS samples. On the receiving side, some data streams should have higher priority so that new data for those streams are processed before lower priority streams.

*Connex* provides user-level configuration of its internal threads that process incoming data. Users may configure *Connex* so that different threads are created with different priorities to process received data of different data streams.

- **Fault-tolerant operation**

Real-time applications are often in control of systems that are required to run in the presence of component failures. Often, those systems are safety critical or carry financial penalties for loss of service. The applications running those systems are usually designed to be fault-tolerant using redundant hardware and software. Backup applications are often “hot” and interconnected to primary systems so that they can take over as soon as a failure is detected.

Publish-subscribe is capable of supporting many-to-many connectivity with redundant *DataWriters* and *DataReaders*. This feature is ideal for constructing fault-tolerant or high-availability applications with redundant nodes and robust fault detection and handling services.

- *Connex* was designed and implemented specifically to address the requirements above through configuration parameters known as QoS Policies defined by the DCPS standard (see [Chapter 42 All QoS Policies on page 683](#)). [Chapter 6 DDS Data Types on page 15](#) introduces basic DCPS terminology and concepts.

If you haven't already, see the [RTI Connex Getting Started Guide](#) for a hands-on introduction to *Connex* basics.

# Chapter 4 Network Communications Models

The communications model underlying the network middleware is the most important factor in how applications communicate. The communications model impacts the performance, the ease to accomplish different communication transactions, the nature of detecting errors, and the robustness to different error conditions. Unfortunately, there is no “one size fits all” approach to distributed applications. Different communications models are better suited to handle different classes of application domains.

This section describes three main types of network communications models:

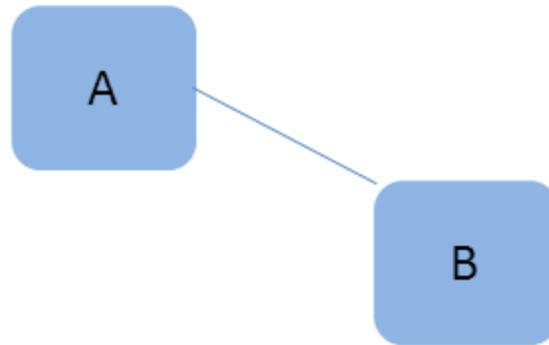

- Point-to-point
- Client-server
- Publish-subscribe

## **Point-to-point model:**

Point-to-point is the simplest form of communication, as illustrated in [Figure 4.1: Point-to-Point on the next page](#). The telephone is an example of an everyday point-to-point communications device. To use a telephone, you must know the address (phone number) of the other party. Once a connection is established, you can have a reasonably high-bandwidth conversation. However, the telephone does not work as well if you have to talk to many people at the same time. The telephone is essentially one-to-one communication.

TCP is a point-to-point network protocol designed in the 1970s. While it provides reliable, high-bandwidth communication, TCP is cumbersome for systems with many communicating nodes.

Figure 4.1: Point-to-Point

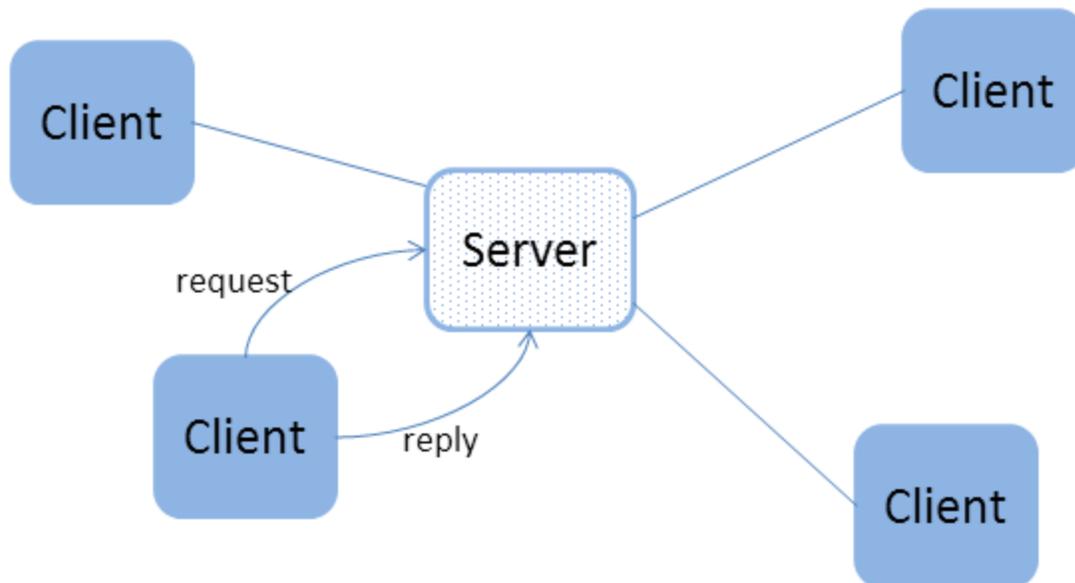

*Point-to-point is one-to-one communication.*

**Client-server model:**

To address the scalability issues of the Point-to-Point model, developers turned to the Client-Server model. Client-server networks designate one special server node that connects simultaneously to many client nodes, as illustrated in [Figure 4.2: Client-Server](#) below.

Figure 4.2: Client-Server

*Client-server is many-to-one communications.*

Client-server is a "many-to-one" architecture. Ordering pizza over the phone is an example of client-server communication. Clients must know the phone number of the pizza parlor to place an order. The parlor can handle many orders without knowing ahead of time where people (clients) are located. After

the order (request), the parlor asks the client where the response (pizza) should be sent. In the client-server model, each response is tied to a prior request. As a result, the response can be tailored to each request. In other words, each client makes a request (order) and each reply (pizza) is made for one specific client in mind.

The client-server network architecture works best when information is centralized, such as in databases, transaction processing systems, and file servers. However, if information is being generated at multiple nodes, a client-server architecture requires that all information are sent to the server for later redistribution to the clients. This approach is inefficient and precludes deterministic communications, since the client does not know when new information is available. The time between when the information is available on the server, and when the client asks and receives it adds a variable latency to the system.

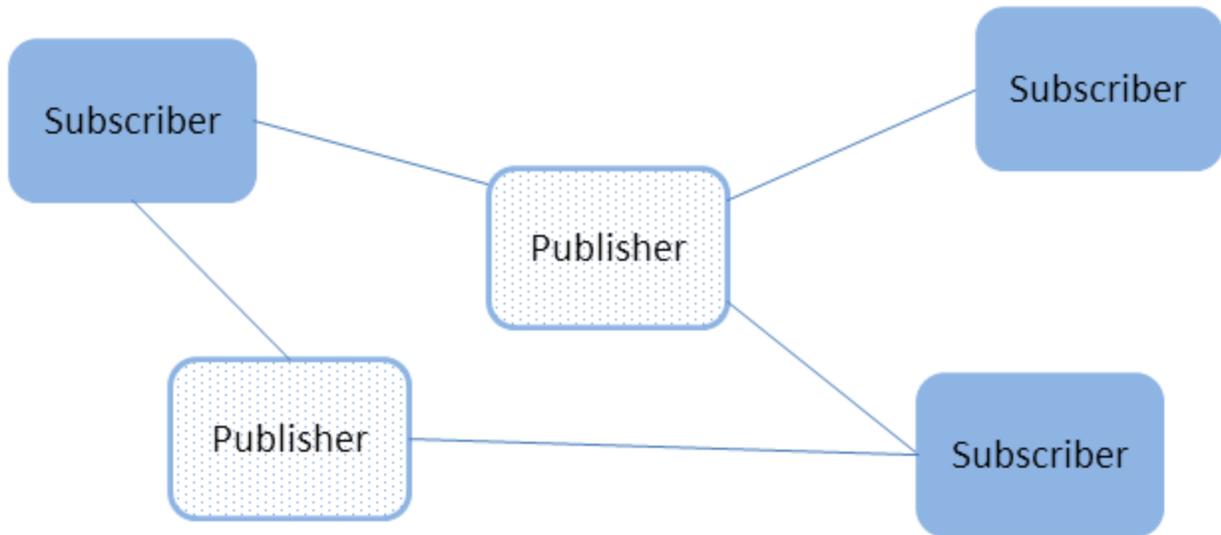

**Publish-subscribe model:** In the publish-subscribe communications model ([Figure 4.3: Publish-Subscribe on the next page](#)), computer applications (nodes) “subscribe” to data they need and “publish” data they want to share. Messages pass directly between the publisher and the subscribers, rather than moving into and out of a centralized server. Most time-sensitive information intended to reach many people is sent by a publish-subscribe system. Examples of publish-subscribe systems in everyday life include television, magazines, and newspapers.

Publish-subscribe communication architectures are good for distributing large quantities of time-sensitive information efficiently, even in the presence of unreliable delivery mechanisms. This direct and simultaneous communication among a variety of nodes makes publish-subscribe network architecture the best choice for systems with complex time-critical data flows.

While the publish-subscribe model provides system architects with many advantages, it may not be the best choice for all types of communications, including:

- File-based transfers (alternate solution: FTP)
- Remote Method Invocation (alternate solutions: CORBA, COM, SOAP)
- Connection-based architectures (alternate solution: TCP/IP)
- Synchronous transfers (alternate solution: CORBA)

Figure 4.3: Publish-Subscribe

*Publish-subscribe is many-to-many communications.*

# Chapter 5 What is a Databus?

Typical distributed systems require data to be shared across multiple devices and multiple networks. This is challenging because the sheer volume of data—not to mention stringent safety and security requirements—can easily overwhelm a network. These challenges require new ways to manage increased data volume, performance requirements, safety risk and security certifications. One of the most important ways to address these challenges is the databus and its unique ability to manage data flow.

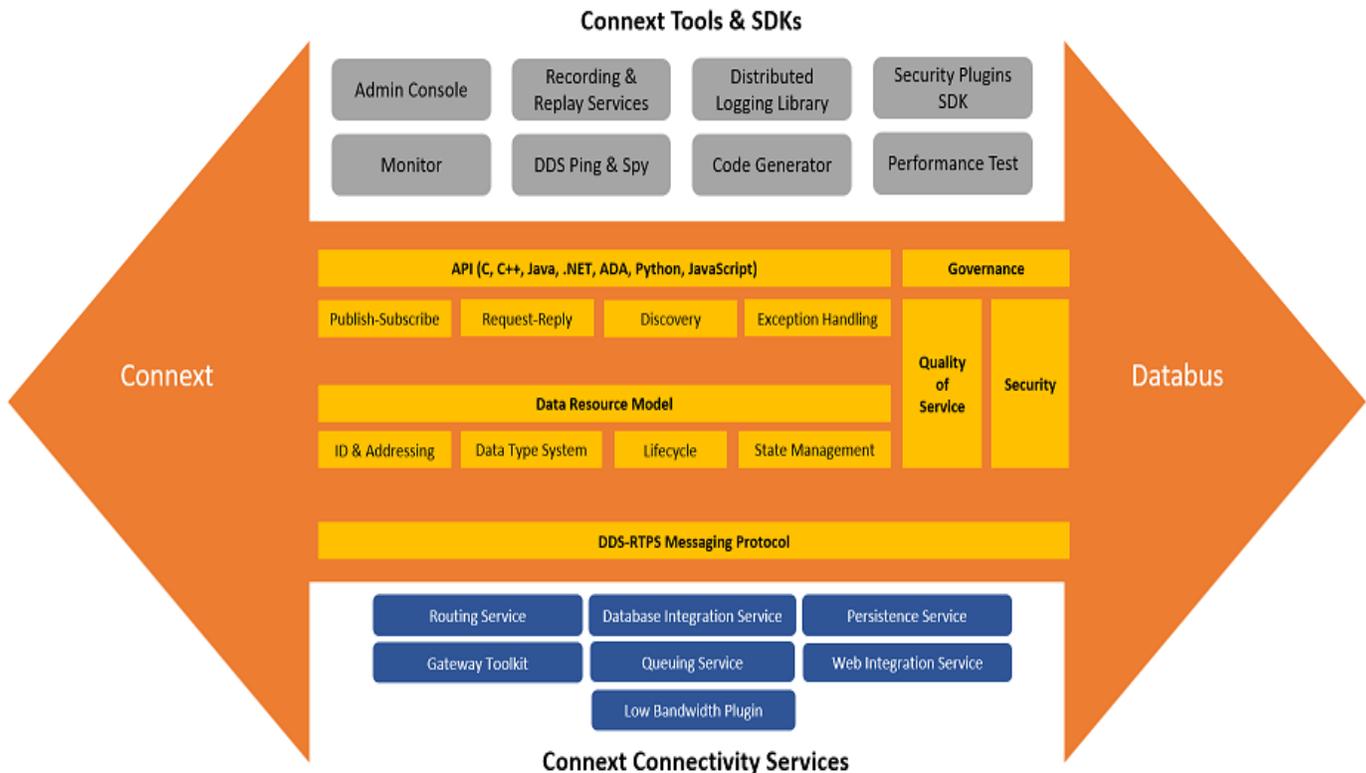

A databus is a data-centric software framework for distributing and managing real-time data in intelligent distributed systems. It allows applications and devices to work together as one, integrated system.

The databus simplifies application and integration logic with a powerful data-centric paradigm. Instead of exchanging messages, software components communicate via shared data objects. Applications directly read and write the value of these objects, which are cached in each participant.

Key characteristics of a databus are:

- The participants/applications directly interface with the data.
- The infrastructure understands, and can therefore selectively filter the data.
- The infrastructure imposes rules and guarantees of Quality of Service (QoS) parameters such as rate, reliability and security of data flow.

Figure 5.1: Connex Databus

## 5.1 Difference between Database and Databus

The databus provides for data in motion, whereas a database provides for data at rest.

A database implements data-centric storage. It saves old information that you can later search by relating properties of the stored data.

A databus implements data-centric interaction. It manages future information by letting you filter by properties of the incoming data. Data-centricity can be defined by these properties:

- The interface is the data. There are no artificial wrappers or blockers to interface such as messages, objects, files or access patterns.
- The infrastructure understands that data. This enables filtering/searching, tools, and selectivity. It decouples applications from the data and thereby removes much of the complexity from the applications.
- The system manages the data and imposes rules on how applications exchange data. This provides a notion of "truth". It enables data lifetimes, data model matching, CRUD interfaces, etc.

It is important to note that a databus is not just a database that you interact with via a pub-sub interface. There is no database. A database implies storage: the data physically resides somewhere. A databus implements a purely virtual concept called a "global data space" and implies data in motion.

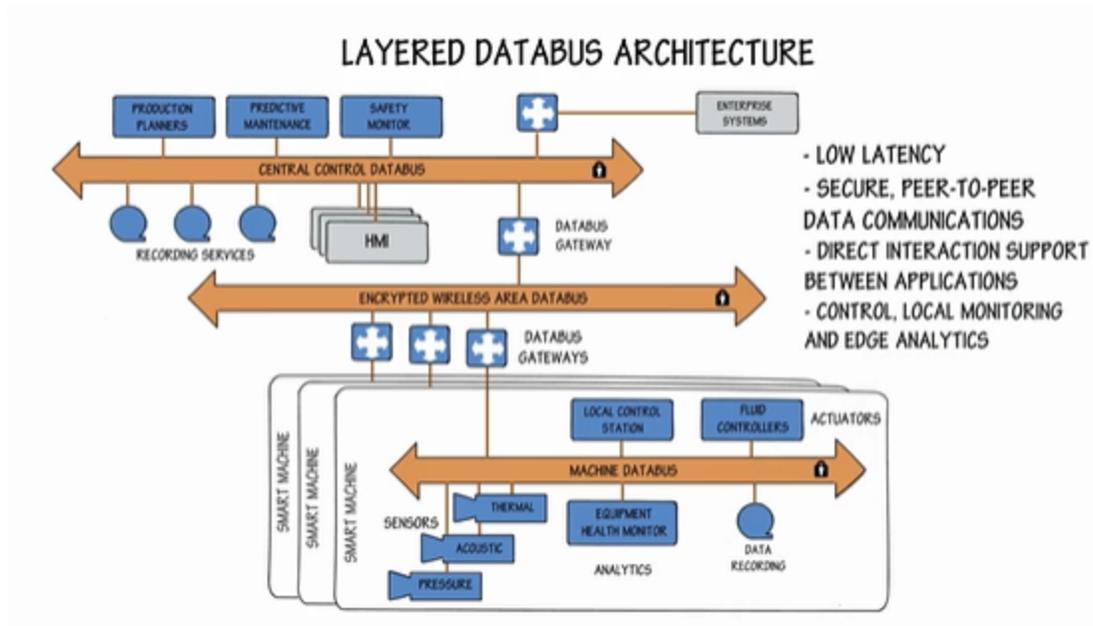

## 5.2 Layered Databus

The Industrial Internet Consortium (IIC) Industrial Internet Reference Architecture (IIRA) is a standards-based architectural guideline for developers to use in designing intelligent distributed systems based on a common framework. The IIRA recommends a new architectural pattern for intelligent distributed systems called the "layered databus" pattern.

In intelligent distributed systems, a common architecture pattern emerges that is made up of multiple databuses layered by communication QoS and data model needs. Typically, databuses will be implemented at the edge in the smart machines or lowest level subsystems, such as in a car, an oil rig, or a hospital room. Above that will be one or more databuses that integrate these smart machines or subsystems, facilitating data communications between and with the higher-level control center or backend systems. The backend or control center layer could be the highest layer databus in the system, but there can be more than these three layers.

Typical distributed systems require sharing data across multiple networks like this. For example, in a connected hospital, devices have to communicate within a patient or operating room, to nurses' stations and off-site monitors, to real-time analytics applications for smart alarming and clinical decision support, and with IT health records. This is challenging for several reasons. The aggregate volume of streaming device data could easily overwhelm hospital networks; patient data must be securely tracked, even as patients and devices move between rooms and networks; and additionally, devices and applications have to interoperate, even when developed by different manufacturers. A layered databus architecture is the ideal framework for resolving these challenges and developing multi-tiered distributed systems of systems.

Figure 5.2: Layered Databus

## Chapter 6 DDS Data Types

In data-centric communications, the applications participating in the communication need to share a common view of the types of data being passed around.

Within different programming languages there are several ‘primitive’ data types that all users of that language naturally share (integers, floating point numbers, characters, booleans, etc.). However, in any non-trivial software system, specialized data types are constructed out of the language primitives. So the data to be shared between applications in the communication system could be structurally simple, using the primitive language types mentioned above, or it could be more complicated, using, for example, C and C++ structs, like this:

```
struct Time {
    int32 year;
    int16 day;
    int16 hour;
    int16 minute;
    int16 second;
};
struct StockPrice {
    float price;
    Time timeStamp;
};
```

Within a set of applications using *Connex*, the different applications do not automatically know the structure of the data being sent, nor do they necessarily interpret it in the same way (if, for instance, they use different operating systems, were written with different languages, or were compiled with different compilers). There must be a way to share not only the data, but also information about how the data is structured.

In *Connex*, data definitions are shared among applications using OMG IDL, a language-independent means of describing data. For more information on data types and IDL, see [Data Types and DDS Data Samples \(Chapter 17 on page 110\)](#).

# Chapter 7 Data Topics

Shared knowledge of the data types is a requirement for different applications to communicate with *Connex*. The applications must also share a way to identify which data is to be shared. Data (of *any* data type) is uniquely distinguished by using a name called a *Topic*. By definition, a *Topic* corresponds to a single data type. However, several *Topics* may refer to the same data type.

*Topics* interconnect *DataWriters* and *DataReaders*. A *DataWriter* is an object in an application that tells *Connex* (and indirectly, other applications) that it has some values of a certain *Topic*. A corresponding *DataReader* is an object in an application that tells *Connex* that it wants to receive values for the same *Topic*. And the data that is passed from the *DataWriter* to the *DataReader* is of the data type associated with the *Topic*. *DataWriters* and *DataReaders* are described more in [Chapter 9 DataWriters/Publishers and DataReaders/Subscribers on page 20](#).

For a concrete example, consider a system that distributes stock quotes between applications. The applications could use a data type called *StockPrice*. There could be multiple *Topics* of the *StockPrice* data type, one for each company's stock, such as IBM, MSFT, GE, etc. Each *Topic* uses the same data type.

Data Type: *StockPrice*

```
struct StockPrice {  
    float price;  
    Time timeStamp;  
};
```

Topic: "IBM"

Topic: "MSFT"

Topic: "GE"

Now, an application that keeps track of the current value of a client's portfolio would subscribe to all of the topics of the stocks owned by the client. As the value of each stock changes, the new price for the corresponding topic is published and sent to the application.

# Chapter 8 DDS Samples, Instances, and Keys

The value of data associated with a *Topic* can change over time. The different values of the *Topic* passed between applications are called DDS samples. In our stock-price example, DDS samples show the price of a stock at a certain point in time. So each DDS sample may show a different price.

For a data type, you can select one or more fields within the data type to form a *key*. A *key* is something that can be used to uniquely identify one *instance* of a *Topic* from another *instance* of the same *Topic*. Think of a key as a way to sub-categorize or group related data values for the same *Topic*. Note that not all data types are defined to have keys, and thus, not all topics have keys. For topics without keys, it's as if there is only a single instance of that topic.

However, for *Topics* with keys, a unique value for the key identifies a unique *instance* of the *Topic*. DDS samples are then updates to particular instances of a *Topic*.

For example, let's change the **StockPrice** data type to include the symbol of the stock. Then instead of having a *Topic* for every stock, which would result in hundreds or thousands of *Topics* and related *DataWriters* and *DataReaders*, each application would only have to publish or subscribe to a single *Topic*, say "StockPrices." Successive values of a stock would be presented as successive DDS samples of an instance of "StockPrices", with each instance corresponding to a single stock symbol.

Data Type: StockPrice

```
struct StockPrice {
    float price;
    Time timeStamp;
    @key char *symbol;
};
```

Instance 1 = (Topic: "StockPrices") + (Key: "MSFT")

sample a, price = \$28.00

sample b, price = \$27.88

Instance 2 = (Topic: “StockPrices”) + (Key: “IBM”)

sample a, price = \$74.02

sample b, price = \$73.50

Etc.

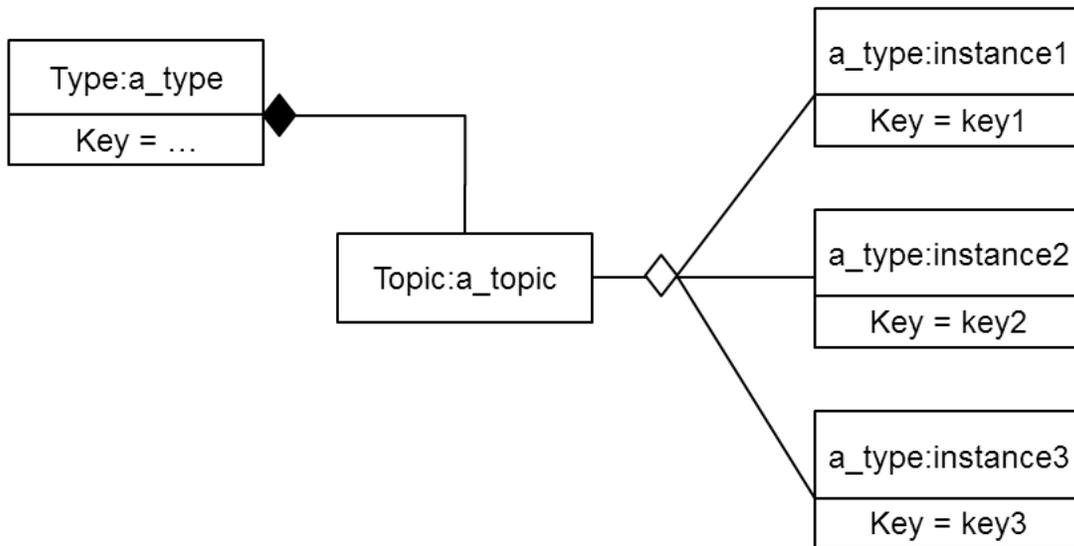

Applications can subscribe to a *Topic* and receive DDS samples for many different instances. Applications can publish DDS samples of one, all, or any number of instances of a *Topic*. Many quality of service parameters actually apply on a *per instance* basis. Keys are also useful for subscribing to a group of related data streams (instances) without pre-knowledge of which data streams (instances) exist at runtime.

For example, just by subscribing to “StockPrices,” an application can get values for all of the stocks through a single topic. In addition, the application does not have to subscribe explicitly to any particular stock, so that if a new stock is added, the application will immediately start receiving values for that stock as well.

Many quality of service (QoS) parameters apply on a per-instance basis because each instance is a unique object and therefore has its own lifecycle, owner, and resource limits.

To summarize, the unique values of data being passed using *Connex*t are called DDS samples. A DDS sample is a combination of a *Topic*, an *instance*, and the actual *user data of a certain data type*. As seen in [Figure 8.1: Relationship of Topics, Keys, and Instances on the next page](#), a *Topic* identifies data of a single type, ranging from one single instance to a whole collection of instances of that given topic for keyed data types. For more information, see [Data Types and DDS Data Samples \(Chapter 17 on page 110\)](#) and [Working with Topics \(Chapter 18 on page 246\)](#).

Figure 8.1: Relationship of Topics, Keys, and Instances

*By using keys, a Topic can identify a collection of data-object instances.*

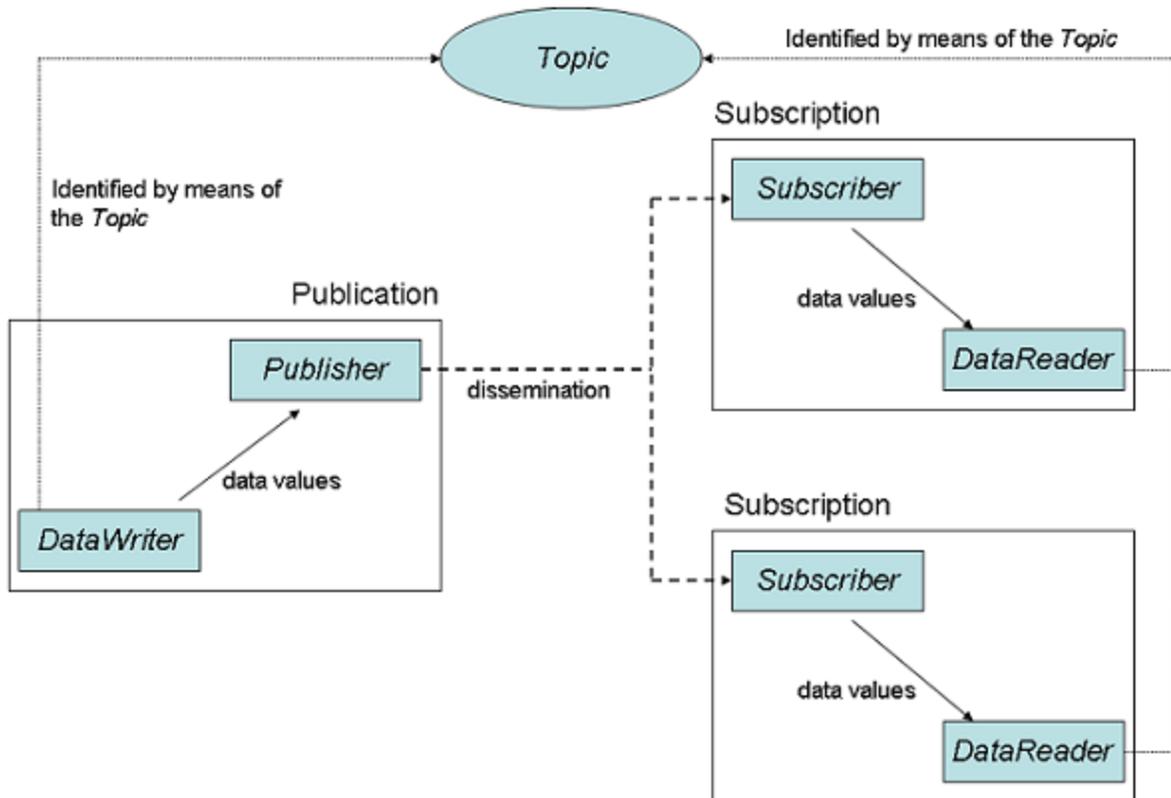

See [Chapter 19 Working with Instances on page 257](#).

# Chapter 9 DataWriters/Publishers and DataReaders/Subscribers

In the *Connex* communication model, applications must use APIs to create entities (objects) in order to establish publish-subscribe communications between each other. The entities and terminology associated with the data itself have been discussed already—*Topics*, keys, instances, DDS samples. This section will introduce the entities that user code must create to send and receive the data. Note that *Entity* is actually a basic concept. In object-oriented terms, *Entity* is the base class from which other DCPS classes—*Topic*, *DataWriter*, *DataReader*, *Publisher*, *Subscriber*, *DomainParticipants*—derive. For general information on Entities, see [Working with DDS Entities \(Chapter 15 on page 32\)](#).

The sending side uses objects called *Publishers* and *DataWriters*. The receiving side uses objects called *Subscribers* and *DataReaders*. [Figure 9.1: Overview on the next page](#) illustrates the relationship of these objects.

Figure 9.1: Overview

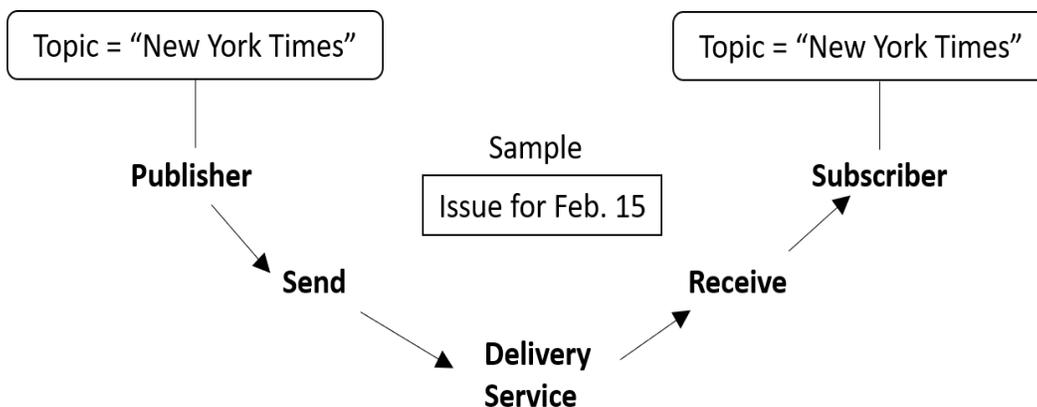

- An application uses *DataWriters* to send data. A *DataWriter* is associated with a single *Topic*. You can have multiple *DataWriters* and *Topics* in a single application. In addition, you can have more than one *DataWriter* for a particular *Topic* in a single application.
- A *Publisher* is the object responsible for the actual sending of data. *Publishers* own and manage *DataWriters*. A *DataWriter* can only be owned by a single *Publisher* while a *Publisher* can own many *DataWriters*. Thus the same *Publisher* may be sending data for many different *Topics* of different data types. When user code calls the `write()` method on a *DataWriter*, the DDS data sample is passed to the *Publisher* object which does the actual dissemination of data on the network. For more information, see [Part 5: Sending Data with Connex](#) (on page 370).
- The association between a *DataWriter* and a *Publisher* is often referred to as a publication, although you never create an object known as a publication.
- An application uses *DataReaders* to access data received over the *Connex* databus. A *DataReader* is associated with a single *Topic*. You can have multiple *DataReaders* and *Topics* in a single application. In addition, you can have more than one *DataReader* for a particular *Topic* in a single application.

- A *Subscriber* is the object responsible for the actual receipt of published data. *Subscribers* own and manage *DataReaders*. A *DataReader* can only be owned by a single *Subscriber* while a *Subscriber* can own many *DataReaders*. Thus the same *Subscriber* may receive data for many different *Topics* of different data types. When data is sent to an application, it is first processed by a *Subscriber*; the DDS data sample is then stored in the appropriate *DataReader*. User code can either register a *listener* to be called when new data arrives or actively poll the *DataReader* for new data using its **read()** and **take()** methods. For more information, see [Overview of Receiving Data \(Chapter 38 on page 594\)](#).
- The association between a *DataReader* and a *Subscriber* is often referred to as a subscription, although you never create an object known as a subscription.

### Example:

The publish-subscribe communications model is analogous to that of magazine publications and subscriptions. Think of a publication as a weekly periodical such as *Newsweek*®. The *Topic* is the name of the periodical (in this case the string "Newsweek"). The *type* specifies the format of the information, e.g., a printed magazine. The *user data* is the contents (text and graphics) of each DDS sample (weekly issue). The middleware is the distribution service (usually the US Postal service) that delivers the magazine from where it is created (a printing house) to the individual subscribers (people's homes). This analogy is illustrated in [Figure 9.2: An Example of Publish-Subscribe below](#). Note that by subscribing to a publication, subscribers are requesting current and future DDS samples of that publication (such as once a week in the case of *Newsweek*), so that as new DDS samples are published, they are delivered without having to submit another request for data.

Figure 9.2: An Example of Publish-Subscribe

*The publish-subscribe model is analogous to publishing magazines. The Publisher sends DDS samples of a particular Topic to all Subscribers of that Topic. With Newsweek® magazine, the Topic would be "Newsweek." The DDS sample consists of the data (articles and pictures) sent to all Subscribers every week. The middleware (Connex) is the distribution channel: all of the planes, trucks, and people who distribute the weekly issues to the Subscribers.*

By default, each DDS sample is propagated individually, independently, and uncorrelated with other DDS samples. However, an application may request that several DDS samples be sent as a coherent set, so that they may be interpreted as such on the receiving side.

# Chapter 10 DDS Entities

Most of the DDS objects an application creates inherit from a common abstract base class, *Entity*. Objects that inherit from *Entity* are referred to as “entities.” The objects used by applications that are responsible for discovery, writing data, and reading data are all entities.

Each specific entity will be covered in detail later in this manual (in [Chapter 15 Working with DDS Entities on page 32](#)), but it’s important to understand the common interface and fundamental behavior common to all entities.

Entities have a common interface for performing certain tasks, including:

- Creating child objects
- Getting and setting Qualities of Service (QoS)

In addition, all entities have status associated with them. The application can query an entity’s status, or be notified when the status changes. Some examples of entity status that will be discussed in more detail in [Chapter 15 Working with DDS Entities on page 32](#):

- A *DataReader* (object that receives data) is an entity that has a `DATA_AVAILABLE` status. The application can query its `DATA_AVAILABLE` status to determine if there is data available for processing.
- A *DataWriter* (object that sends data) is an entity that has a `DEADLINE_MISSED` status. The application can query its `DEADLINE_MISSED` status to determine if the *DataWriter* has not sent data on time.

The application can access an *Entity*’s status by:

- Querying the status at any time by calling `get_status_changes()` on the *Entity*.

- Being notified of an *Entity's* status change by installing a Listener object on the *Entity* that will call the application from a *Connex* thread to notify the application of a status change.
- Being notified of an *Entity's* status change by using StatusCondition and WaitSet objects that will block an application thread until a status change.

More information is provided in [Chapter 15 Working with DDS Entities on page 32](#).

# Chapter 11 Quality of Service (QoS)

The publish-subscribe approach to distributed communications is a generic mechanism that can be employed by many different types of systems. The model described here extends the publish-subscribe model to address the needs of real-time, data-critical applications. It provides standardized mechanisms, known as Quality of Service Policies, that allow application developers to configure how communications occur, to limit resources used by the middleware, to detect system incompatibilities and setup error handling routines.

QoS Policies control many aspects of how and when data is distributed between applications. The overall QoS of the *Connex* system is made up of the individual QoS Policies for each DCPS *Entity*. There are QoS Policies for *Topics*, *DataWriters*, *Publishers*, *DataReaders*, *Subscribers*, and *DomainParticipants*.

On the publishing side, the QoS of each *Topic*, the *Topic's DataWriter*, and the *DataWriter's Publisher* all play a part in controlling how and when DDS samples are sent to the middleware. Similarly, the QoS of the *Topic*, the *Topic's DataReader*, and the *DataReader's Subscriber* control behavior on the subscribing side.

Users will employ QoS Policies to control a variety of behaviors. For example, the DEADLINE policy sets up expectations of how often a *DataReader* expects to see DDS samples. The OWNERSHIP and OWNERSHIP\_STRENGTH policy are used together to configure and arbitrate whose data is passed to the *DataReader* when there are multiple *DataWriters* for the same instance of a *Topic*. The HISTORY policy specifies whether a *DataWriter* should save old data to send to new subscriptions that join the network later. Many other policies exist and they are presented in [Chapter 42 All QoS Policies on page 683](#).

Some QoS Policies represent “contracts” between publications and subscriptions. For communications to take place properly, the QoS Policies set on the *DataWriter* side must be compatible with corresponding policies set on the *DataReader* side.

For example, the RELIABILITY policy is set by the *DataWriter* to state whether it is configured to send data reliably to *DataReaders*. Because it takes additional resources to send data reliably, some *DataWriters* may only support a best-effort level of reliability. This implies that

for those *DataWriters*, *Connex*t will not spend additional effort to make sure that the data sent is received by *DataReaders* or resend any lost data. However, for certain applications, it could be imperative that their *DataReaders* receive every piece of data with total reliability. Running a system where the *DataWriters* have not been configured to support the *DataReaders* could lead to erratic failures.

To address this issue, and yet keep the publications and subscriptions as decoupled as possible, *Connex*t provides a way to detect and notify when QoS Policies set by *DataWriters* and *DataReaders* are incompatible. *Connex*t employs a pattern known as RxO (Requested versus Offered). The *DataReader* sets a “requested” value for a particular QoS Policy. The *DataWriter* sets an “offered” value for that QoS Policy. When *Connex*t matches a *DataReader* to a *DataWriter*, QoS Policies are checked to make sure that all requested values can be supported by the offered values.

Note that not all QoS Policies are constrained by the RxO pattern. For example, it does not make sense to compare policies that affect only the *DataWriter* but not the *DataReader* or vice versa.

If the *DataWriter* cannot satisfy the requested QoS Policies of a *DataReader*, *Connex*t will not connect the two DDS entities and will notify the applications on each side of the incompatibility if so configured.

For example, a *DataReader* sets its DEADLINE QoS to 4 seconds—that is, the *DataReader* is *requesting* that it receive new data at least every 4 seconds.

In one application, the *DataWriter* sets its DEADLINE QoS to 2 seconds—that is, the *DataWriter* is committing to sending data at least every 2 seconds. This writer can satisfy the request of the reader, and thus, *Connex*t will pass the data sent from the writer to the reader.

In another application, the *DataWriter* sets its DEADLINE QoS to 5 seconds. It only commits to sending data at 5 second intervals. This will not satisfy the request of the *DataReader*. *Connex*t will flag this incompatibility by calling user-installed listeners in both *DataWriter* and *DataReader* applications and not pass data from the writer to the reader.

For a summary of the QoS Policies supported by *Connex*t, see [Chapter 42 All QoS Policies on page 683](#).

# Chapter 12 DDS Domains and DomainParticipants

You may have several independent *Connex*t applications all running on the same set of computers. You may want to isolate one (or more) of those applications so that it isn't affected by the others. To address this issue, *Connex*t has a concept called *DDS domains*.

DDS domains represent logical, isolated, communication networks. Multiple applications running on the same set of hosts on different DDS domains are completely isolated from each other (even if they are on the same machine). *DataWriters* and *DataReaders* belonging to different DDS domains will never exchange data.

Applications that want to exchange data using *Connex*t must belong to the same DDS domain. To belong to a DDS domain, *Connex*t APIs are used to configure and create a *DomainParticipant* with a specific *Domain Index*. DDS domains are differentiated by the *domain index* (an integer value). Applications that have created *DomainParticipants* with the same *domain index* belong to the same DDS domain. *DomainParticipants* own *Topics*, *Publishers*, and *Subscribers*, which in turn owns *DataWriters* and *DataReaders*. Thus all *Connex*t Entities belong to a specific DDS domain.

An application may belong to multiple DDS domains simultaneously by creating multiple *DomainParticipants* with different domain indices. However, *Publishers/DataWriters* and *Subscribers/DataReaders* only belong to the DDS domain in which they were created.

As mentioned before, multiple DDS domains may be used for application isolation, which is useful when you are testing applications using computers on the same network or even the same computers. By assigning each user different domains, one can guarantee that the data produced by one user's application won't accidentally be received by another. In addition, DDS domains may be a way to scale and construct larger systems that are composed of multi-node subsystems. Each subsystem would use an internal DDS domain for intra-system communications and an external DDS domain to connect to other subsystems.

For more information, see [Working with DDS Domains \(Chapter 16 on page 72\)](#).

# Chapter 13 Application Discovery

The data-centric publish-subscribe model provides anonymous, transparent, many-to-many communications. Each time an application sends a DDS sample of a particular *Topic*, the middleware distributes the DDS sample to all the applications that want that *Topic*. The publishing application does not need to specify how many applications receive the *Topic*, nor where those applications are located. Similarly, *subscribing applications* do not specify the location of the publications. In addition, new publications and *subscriptions* of the *Topic* can appear at any time, and the middleware will automatically interconnect them.

So how is this all done? Ultimately, in each application for each publication, *Connex*t must keep a list of applications that have subscribed to the same *Topic*, nodes on which they are located, and some additional QoS parameters that control how the data is sent. Also, *Connex*t must keep a list of applications and publications for each of the *Topics* to which the application has subscribed.

Propagation of this information (the existence of publications and subscriptions and associated QoS) between applications by *Connex*t is known as the *discovery* process. While the DDS (DCPS) standard does not specify how discovery occurs, *Connex*t uses a standard protocol RTPS for both discovery and formatting on-the-wire packets.

When a *DomainParticipant* is created, *Connex*t sends out packets on the network to announce its existence. When an application finds out that another application belongs to the same DDS domain, then it will exchange information about its existing publications and subscriptions and associated QoS with the other application. As new *DataWriters* and *DataReaders* are created, this information is sent to known applications.

The *Discovery* process is entirely configurable by the user and is discussed extensively in [Discovery Overview \(Chapter 22 on page 309\)](#).

# Chapter 14 XML Configuration

*Connex* entities can be configured using XML rather than hard-coding configuration in the code. This allows you to separate application development from configuration. Using XML, you can change your configuration without recompiling.

XML can be used to configure:

- Quality of Service (QoS) parameters. See [Part 7: Configuring Connex Using QoS on page 682](#).
- Creation of entities such as *DomainParticipants*, *DataWriters*, and *DataReaders*. See the [RTI Connex Core Libraries XML-Based Application Creation Getting Started Guide](#).

## Part 2: Building Blocks of Connex: Entities and Domains

It's important to understand the building blocks of *Connex* in order to design applications that can take advantage of all of the features of *Connex*.

That means first understanding the common abstract base class that most *Connex* objects inherit from: *Entity*. Objects that inherit from the *Entity* abstract base class will be referred to as “entities” in this document. *Entities* inherit:

- Common interfaces from the *Entity* class.
- Statuses that can be queried. The specific statuses of an *Entity* are directly related to what that *Entity* does. However, the mechanisms for being notified of status changes and accessing those statuses are common to all *Entities*.

It's important to understand *Entities* before diving into *DataWriter* entities (in [Part 5: Sending Data with Connex on page 370](#)) and *DataReader* entities (in [Part 6: Receiving Data with Connex on page 593](#)).

The second important building blocks to understand are the *DomainParticipantFactory* and *DomainParticipant* entities. Those are the first objects an application must create to communicate in a DDS system. The *DomainParticipant* entity is particularly important because it is responsible for the discovery process.

Part 2 discusses the building blocks of *Connex*:

- [Working with DDS Entities \(Chapter 15 on page 32\)](#)
- [Working with DDS Domains \(Chapter 16 on page 72\)](#)

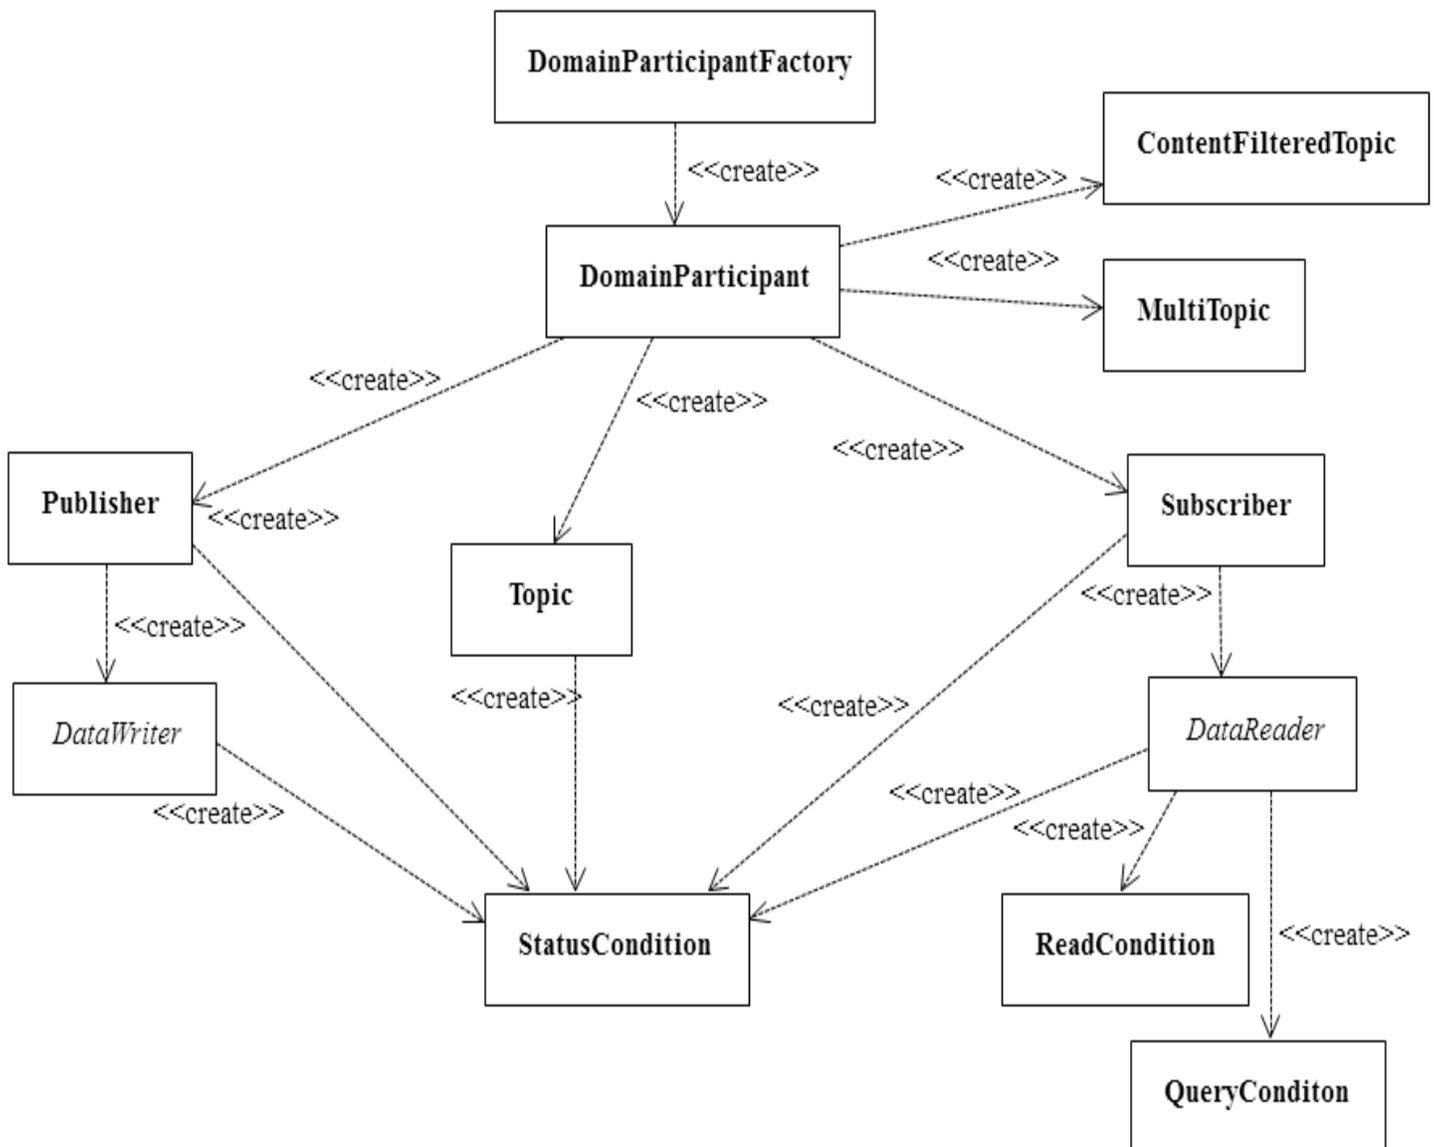

# Chapter 15 Working with DDS Entities

The main classes extend an abstract base class called a *DDS Entity*. Every *DDS Entity* has a set of associated events known as statuses and a set of associated Quality of Service Policies (QosPolicies). In addition, a *Listener* may be registered with the *Entity* to be called when status changes occur. *DDS Entities* may also have attached *DDS Conditions*, which provide a way to wait for status changes. [Figure 15.1: Overview of DDS Entities on the next page](#) presents an overview in a UML diagram.

This section describes the common operations and general designed patterns shared by all *DDS Entities* including *DomainParticipants*, *Topics*, *Publishers*, *DataWriters*, *Subscribers*, and *DataReaders*.

In subsequent sections, the specific statuses, *Listeners*, *Conditions*, and QosPolicies for each class will be discussed in detail.

Figure 15.1: Overview of DDS Entities

## 15.1 Creating and Deleting DDS Entities

- C, Traditional C++, Java, and .NET:

The factory design pattern is used in creating and deleting DDS *Entities*. Instead of declaring and constructing or destructing *Entities* directly, a factory object is used to create an *Entity*. Almost all *Entity* factories are objects that are also *Entities*. The only exception is the factory for a *DomainParticipant*. See [Table 15.1 Entity Factories](#).

Table 15.1 Entity Factories

Entity	Created by
<i>DomainParticipant</i>	DomainParticipantFactory (a static singleton object provided by <i>Connex</i> )
<i>Topic</i>	<i>DomainParticipant</i>
<i>Publisher</i>	
<i>Subscriber</i>	
<i>DataWriter</i>	
<i>DataReader</i>	
<i>DataWriter</i>	<i>Publisher</i>
<i>DataReader</i>	<i>Subscriber</i>

All *Entities* that are factories have:

- Operations to create and delete child *Entities*. For example:

**DDSPublisher::create\_datawriter()**

**DDSDomainParticipant::delete\_topic()**

- Operations to get and set the default QoS values used when creating child *Entities*. For example:

**DDSSubscriber::get\_default\_datareader\_qos()**

**DDSDomainParticipantFactory::set\_default\_participant\_qos()**

- And [46.2 ENTITYFACTORY QosPolicy on page 743](#) to specify whether or not the newly created child *Entity* should be automatically enabled upon creation.

*DataWriters* may be created by a *DomainParticipant* or a *Publisher*. Similarly, *DataReaders* may be created by a *DomainParticipant* or a *Subscriber*.

An entity that is a factory cannot be deleted until *all* the child *Entities* created by it have been deleted.

Each *Entity* obtained through **create\_<entity>()** must eventually be deleted by calling **delete\_<entity>()**, or by calling **delete\_contained\_entities()**.

- Modern C++:

In the Modern C++ API the factory pattern is not explicit. Entities have constructors and destructors. The first argument to an Entity's constructor is its "factory" (except for the *DomainParticipant*). For example:

```
// Note: this example shows the simplest version of each Entity's constructor:
dds::domain::DomainParticipant participant(MY_DOMAIN_ID);
dds::topic::Topic<Foo> topic(participant, "Example Foo");
dds::sub::Subscriber subscriber(participant);
dds::sub::DataReader<Foo> reader(subscriber, topic);
dds::pub::Publisher publisher(participant);
dds::pub::DataWriter<Foo> writer(publisher, topic);
```

Entities are *reference types*. In a reference type copy operations, such as copy-construction and copy-assignment are shallow. The reference types are modeled after shared pointers. Similar to pointers, it is important to distinguish between an entity and a reference (or handle) to it. A single entity may have multiple references. Copying a reference does not copy the entity it is referring to—creating additional references from the existing reference(s) is a relatively inexpensive operation.

The lifecycle of references and the entity they are referring to is not the same. In general, the entity lives as long as there is at least one reference to it. When the last reference to the entity ceases to exist, the entity it is referring to is destroyed.

Applications can override the automatic destruction of Entities. An Entity can be explicitly closed (by calling the method `close()`) or retained (by calling `retain()`)

Closing an Entity destroys the underlying object and invalidates all references to it.

Retaining an Entity disables the automatic destruction when it loses all its reference. A retained Entity can be looked up (see [16.2.4 Looking Up DomainParticipants on page 80](#)) and has to be explicitly destroyed with `close()`.

## 15.2 Enabling DDS Entities

The `enable()` operation changes an *Entity* from a non-operational to an operational state. *Entity* objects can be created disabled or enabled. This is controlled by the value of the [46.2 ENTITYFACTORY QoS Policy on page 743](#) on the corresponding *factory* for the *Entity* (not on the *Entity* itself).

By default, all *Entities* are automatically created in the enabled state. This means that as soon as the *Entity* is created, it is ready to be used. In some cases, you may want to create the *Entity* in a ‘disabled’ state. For example, by default, as soon as you create a *DataReader*, the *DataReader* will start receiving new DDS samples for its *Topic* if they are being sent. However, your application may still be initializing other components and may not be ready to process the data at that time. In that case, you can tell the *Subscriber* to create the *DataReader* in a disabled state. After all of the other parts of the application have been created and initialized, then the *DataReader* can be enabled to actually receive messages.

To create a particular entity in a disabled state, modify the *EntityFactory* *QoSPolicy* of its corresponding *factory* *entity* before calling `create_<entity>()`. For example, to create a disabled *DataReader*, modify the *Subscriber*’s *QoS* as follows:

```
DDS_SubscriberQos subscriber_qos;
subscriber->get_qos(subscriber_qos);
subscriber_qos.entity_factory.autoenable_created_entities = DDS_BOOLEAN_FALSE;
subscriber->set_qos(subscriber_qos);
DDSDataReader* datareader =
    subscriber->create_datareader(topic, DDS_DATAREADER_QOS_DEFAULT, listener);
```

When the application is ready to process received data, it can enable the *DataReader*:

```
datareader->enable();
```

## 15.2.1 Rules for Calling enable()

In the following, a ‘Factory’ refers to a *DomainParticipant*, *Publisher*, or *Subscriber*; a ‘child’ refers to an entity created by the factory:

- If the factory is disabled, its children are always created disabled.
- If the factory is enabled, its children will be created according to the setting in the factory's EntityFactoryQoS value.
- Calling **enable()** on a child whose factory object is still disabled will fail and return `DDS_RECODE_RECONDITION_NOT_MET`.
- Calling **enable()** on a factory with EntityFactoryQoS set to `DDS_BOOLEAN_TRUE` will *recursively* enable all of the factory's children. If the factory's EntityFactoryQoS is set to `DDS_BOOLEAN_FALSE`, only the factory itself will be enabled.
- Calling **enable()** on an entity that is already enabled returns `DDS_RETCODE_OK` and has no effect.
- There is no complementary “**disable**” operation. You cannot disable an entity after it is enabled. Disabled *Entities* must have been created in that state.
- An entity's *Listener* will only be invoked if the entity is enabled.
- The existence of an entity is not propagated to other *DomainParticipants* until the entity is enabled (see [Discovery Overview \(Chapter 22 on page 309\)](#)).
- If a *DataWriter/DataReader* is to be created in an enabled state, then the associated *Topic* must already be enabled. The enabled state of the *Topic* does not matter, if the *Publisher/Subscriber* has its EntityFactory QoSPolicy to create children in a disabled state.
- When calling **enable()** for a *DataWriter/DataReader*, both the *Publisher/Subscriber* and the *Topic* must be enabled, or the operation will fail and return `DDS_RETCODE_PRECONDITION_NOT_MET`.

The following operations may be invoked on disabled *Entities*:

- **get\_qos()** and **set\_qos()** Some DDS-specified QoS Policies are *immutable*—they cannot be changed after an *Entity* is enabled. This means that for those policies, if the entity was created in

the disabled state, `get/set_qos()` can be used to change the values of those policies until `enabled()` is called on the *Entity*. After the *Entity* is enabled, changing the values of those policies will not affect the *Entity*. However, there are *mutable* QoS Policies whose values can be changed at anytime—even after the *Entity* has been enabled.

Finally, there are extended QoS Policies that are not a part of the DDS specification but offered by *Connex* to control extended features for an *Entity*. Some of those extended QoS Policies cannot be changed after the *Entity* has been created—regardless of whether the *Entity* is enabled or disabled.

Into which exact categories a QoS Policy falls—mutable at any time, immutable after enable, immutable after creation—is described in the documentation for the specific policy.

- `get_status_changes()` and `get_*_status()`The status of an *Entity* can be retrieved at any time (but the status of a disabled *Entity* never changes). (Note: `get_*_status()` resets the related status so it no longer considered “changed.”)
- `get_statuscondition()`An *Entity's StatusCondition* can be checked at any time (although the status of a disabled *Entity* never changes).
- `get_listener()` and `set_listener()`An *Entity's Listener* can be changed at any time.
- `create_*` and `delete_*`A factory *Entity* can still be used to create or delete any child *Entity* that it can produce. Note: following the rules discussed previously, a disabled *Entity* will always create its children in a disabled state, no matter what the value of the *EntityFactory* QoS Policy is.
- `lookup_*`An *Entity* can always look up children it has previously created.

Most other operations are not allowed on disabled *Entities*. Executing one of those operations when an *Entity* is disabled will result in a return code of `DDS_RETCODE_NOT_ENABLED`. The documentation for a particular operation will explicitly state if it is not allowed to be used if the *Entity* is disabled.

The builtin transports are implicitly registered when (a) the *DomainParticipant* is enabled, (b) the first *DataWriter/DataReader* is created, or (c) you look up a builtin data reader, whichever happens first. Any changes to the builtin transport properties that are made after the builtin transports have been registered will have no affect on any *DataWriters/DataReaders*.

## 15.3 Getting an Entity's Instance Handle

The *Entity* class provides an operation to retrieve an instance handle for the object. The operation is simply:

```
InstanceHandle_t get_instance_handle()
```

An instance handle is a global ID for the entity that can be used in methods that allow user applications to determine if the entity was locally created, if an entity is owned (created) by another entity, etc.

## 15.4 Getting Status and Status Changes

The `get_status_changes()` operation retrieves the set of events, also known in DDS terminology as *communication statuses*, in the *Entity* that have changed since the last time `get_status_changes()` was called. This method actually returns a value that must be bitwise AND'ed with an enumerated bit mask to test whether or not a specific status has changed. The operation can be used in a polling mechanism to see if any statuses related to the *Entity* have changed. If an entity is disabled, all communication statuses are in the “unchanged” state so the list returned by the `get_status_changes()` operation will be empty.

A set of statuses is defined for each class of *Entities*. For each status, there is a corresponding operation, `get_<status-name>_status()`, that can be used to get its current value. For example, a *DataWriter* has a `DDS_OFFERED_DEADLINE_MISSED` status; it also has a `get_offered_deadline_missed_status()` operation:

```
DDS_StatusMask statuses;
DDS_OfferedDeadlineMissedStatus deadline_stat;
statuses = datawriter->get_status_changes();
if (statuses & DDS_OFFERED_DEADLINE_MISSED_STATUS) {
datawriter->get_offered_deadline_missed_status(
    &deadline_stat);
    printf("Deadline missed %d times.\n",
        deadline_stat.total_count);
}
```

To reset a status (so that it is no longer considered “changed”), call `get_<status-name>_status()`. Or, in the case of the `DDS_DATA_AVAILABLE` status, call `read()`, `take()`, or one of their variants.

If you use a *StatusCondition* to be notified that a particular status has changed, the *StatusCondition*'s `trigger_value` will remain true unless you call `get_*_status()` to reset the status.

See also: [15.7 Statuses on the next page](#) and [15.9.8 StatusConditions on page 69](#).

## 15.5 Getting and Setting Listeners

Each type of *Entity* has an associated *Listener*, see [15.8 Listeners on page 46](#). A *Listener* represents a set of functions that users may install to be called asynchronously when the state of *communication statuses* change.

The `get_listener()` operation returns the current *Listener* attached to the *Entity*.

The `set_listener()` operation installs a *Listener* on an *Entity*. The *Listener* will only be invoked on the changes of statuses specified by the accompanying mask. Only one listener can be attached to each *Entity*. If a *Listener* was already attached, `set_listener()` will replace it with the new one.

The `get_listener()` and `set_listener()` operations are directly provided by the *DomainParticipant*, *Topic*, *Publisher*, *DataWriter*, *Subscriber*, and *DataReader* classes so that listeners and masks used in the argument list are specific to each *Entity*.

**Note:** The `set_listener()` operation is not synchronized with the listener callbacks, so it is possible to set a new listener on an participant while the old listener is in a callback. Therefore you should be careful not to delete any listener that has been set on an enabled participant unless some application-specific means are available of ensuring that the old listener cannot still be in use.

See [15.8 Listeners on page 46](#) for more information about *Listeners*.

## 15.6 Getting the StatusCondition

Each type of *Entity* may have an attached *StatusCondition*, which can be accessed through the `get_statuscondition()` operation. You can attach the *StatusCondition* to a *WaitSet*, to cause your application to wait for specific status changes that affect the *Entity*.

See [15.9 Conditions and WaitSets on page 59](#) for more information about *StatusConditions* and *WaitSets*.

## 15.7 Statuses

This section describes the different *statuses* that exist for an entity. A status represents a state or an event regarding the entity. For instance, maybe *Connex* found a matching *DataReader* for a *DataWriter*, or new data has arrived for a *DataReader*.

Your application can retrieve an *Entity*'s status by:

- explicitly checking for *any* status changes with `get_status_changes()`.
- explicitly checking a *specific* status with `get_<status_name>_status()`.
- using a *Listener*, which provides asynchronous notification when a status changes.
- using *StatusConditions* and *WaitSets*, which provide a way to wait for status changes.

If you want your application to be notified of status changes asynchronously: create and install a *Listener* for the *Entity*. Then internal *Connex* threads will call the listener methods when the status changes. See [15.8 Listeners on page 46](#).

If you want your application to wait for status changes: set up *StatusConditions* to indicate the statuses of interest, attach the *StatusConditions* to a *WaitSet*, and then call the *WaitSet*'s `wait()` operation. The call to `wait()` will block until statuses in the attached *Conditions* changes (or until a timeout period expires). See [15.9 Conditions and WaitSets on page 59](#).

## 15.7.1 Types of Communication Status

Each *Entity* is associated with a set of *Status* objects representing the “communication status” of that *Entity*. The list of statuses actively monitored by *Connex* is provided in [Table 15.2 Communication Statuses](#). A status structure contains values that give you more information about the status; for example, how many times the event has occurred since the last time the user checked the status, or how many time the event has occurred in total.

Changes to status values cause activation of corresponding *StatusCondition* objects and trigger invocation of the corresponding *Listener* functions to asynchronously inform the application that the status has changed. For example, a change in a *Topic*'s **INCONSISTENT\_TOPIC\_STATUS** may trigger the *TopicListener*'s **on\_inconsistent\_topic()** callback routine (if such a *Listener* is installed).

**Table 15.2 Communication Statuses**

Related Entity	Status (DDS_*_STATUS)	Description	Reference
Topic	INCONSISTENT_TOPIC	Another <i>Topic</i> exists with the same name but different characteristics—for example, a different type.	<a href="#">18.2.1 INCONSISTENT_TOPIC Status on page 256</a>
DataWriter	APPLICATION_ACKNOWLEDGMENT	This status indicates that a <i>DataWriter</i> has received an application-level acknowledgment for a DDS sample. The listener provides the identities of the DDS sample and acknowledging <i>DataReader</i> , as well as user-specified response data sent from the <i>DataReader</i> by the acknowledgment message.	<a href="#">31.12 Application Acknowledgment on page 418</a>
	DATA_WRITER_CACHE	The status of the <i>DataWriter</i> 's cache. This status does not have a Listener.	<a href="#">31.6.2 DATA_WRITER_CACHE_STATUS on page 398</a>
	DATA_WRITER_PROTOCOL	The status of a <i>DataWriter</i> 's internal protocol related metrics (such as the number of DDS samples pushed, pulled, filtered) and the status of wire protocol traffic. This status does not have a Listener.	<a href="#">31.6.3 DATA_WRITER_PROTOCOL_STATUS on page 399</a>

Table 15.2 Communication Statuses

Related Entity	Status (DDS_*_STATUS)	Description	Reference
DataWriter cont'd	LIVELINESS_LOST	The liveliness that the <i>DataWriter</i> has committed to (through its Liveliness QoSPolicy) was not respected ( <code>assert_liveliness()</code> or <code>write()</code> not called in time), thus <i>DataReaders</i> may consider the <i>DataWriter</i> as no longer active.	<a href="#">31.6.4 LIVELINESS_LOST Status on page 403</a>
	OFFERED_DEADLINE_MISSED	The deadline that the <i>DataWriter</i> has committed through its Deadline QoSPolicy was not respected for a specific instance of the <i>Topic</i> .	<a href="#">31.6.5 OFFERED_DEADLINE_MISSED Status on page 404</a>
	OFFERED_INCOMPATIBLE_QOS	An offered QoSPolicy value was incompatible with what was requested by a <i>DataReader</i> of the same <i>Topic</i> .	<a href="#">31.6.6 OFFERED_INCOMPATIBLE_QOS Status on page 404</a>
	PUBLICATION_MATCHED	The <i>DataWriter</i> found a <i>DataReader</i> that matches the <i>Topic</i> , has compatible QoSs and a common partition, or a previously matched <i>DataReader</i> has been deleted.	<a href="#">31.6.7 PUBLICATION_MATCHED Status on page 405</a>
	RELIABLE_WRITER_CACHE_CHANGED	The number of unacknowledged DDS samples in a reliable <i>DataWriter's</i> cache has reached one of the predefined trigger points.	<a href="#">31.6.8 RELIABLE_WRITER_CACHE_CHANGED Status (DDS Extension) on page 406</a>
	RELIABLE_READER_ACTIVITY_CHANGED	One or more reliable <i>DataReaders</i> has either been discovered, deleted, or changed between active and inactive state as specified by the LivelinessQoSPolicy of the <i>DataReader</i> .	<a href="#">31.6.9 RELIABLE_READER_ACTIVITY_CHANGED Status (DDS Extension) on page 408</a>
Subscriber	DATA_ON_READERS	New data is available for any of the readers that were created from the <i>Subscriber</i> .	<a href="#">39.9 Statuses for Subscribers on page 613</a>
DataReader	DATA_AVAILABLE	New data (one or more DDS samples) are available for the specific <i>DataReader</i> .	<a href="#">40.7.1 DATA_AVAILABLE Status on page 627</a>
	DATA_READER_CACHE	The status of the reader's cache. This status does not have a Listener.	<a href="#">40.7.2 DATA_READER_CACHE_STATUS on page 627</a>
	DATA_READER_PROTOCOL	The status of a <i>DataReader's</i> internal protocol related metrics (such as the number of DDS samples received, filtered, rejected) and the status of wire protocol traffic. This status does not have a Listener.	<a href="#">40.7.3 DATA_READER_PROTOCOL_STATUS on page 630</a>
	LIVELINESS_CHANGED	The liveliness of one or more <i>DataWriters</i> that were writing instances read by the <i>DataReader</i> has either been discovered, deleted, or changed between active and inactive state as specified by the LivelinessQoSPolicy of the <i>DataWriter</i> .	<a href="#">40.7.4 LIVELINESS_CHANGED Status on page 634</a>

Table 15.2 Communication Statuses

Related Entity	Status (DDS_*_STATUS)	Description	Reference
DataReader cont'd	REQUESTED_DEADLINE_MISSED	New data was not received for an instance of the <i>Topic</i> within the time period set by the <i>DataReader</i> 's Deadline QoSPolicy.	<a href="#">40.7.5 REQUESTED_DEADLINE_MISSED Status on page 635</a>
	REQUESTED_INCOMPATIBLE_QOS	A requested QoSPolicy value was incompatible with what was offered by a <i>DataWriter</i> of the same <i>Topic</i> .	<a href="#">40.7.6 REQUESTED_INCOMPATIBLE_QOS Status on page 636</a>
	SAMPLE_LOST	A DDS sample sent by <i>Connex</i> t has been lost (never received).	<a href="#">40.7.7 SAMPLE_LOST Status on page 636</a>
	SAMPLE_REJECTED	A received DDS sample has been rejected due to a resource limit (buffers filled).	<a href="#">40.7.8 SAMPLE_REJECTED Status on page 640</a>
	SUBSCRIPTION_MATCHED	The <i>DataReader</i> has found a <i>DataWriter</i> that matches the <i>Topic</i> , has compatible QoSs and a common partition, or an existing matched <i>DataWriter</i> has been deleted.	<a href="#">40.7.9 SUBSCRIPTION_MATCHED Status on page 642</a>

Statuses can be grouped into two categories:

- Plain communication status:

In addition to a flag that indicates whether or not a status has changed, a *plain* communication status also contains state and thus has a corresponding structure to hold its current value.

- Read communication status:

A read communication status is more like an event and has no state other than whether or not it has occurred. Only two statuses listed in [Table 15.2 Communication Statuses](#) are *read* communications statuses: **DATA\_AVAILABLE** and **DATA\_ON\_READERS**.

As mentioned in [15.4 Getting Status and Status Changes on page 38](#), all *Entities* have a **get\_status\_changes()** operation that can be used to explicitly poll for changes in any status related to the entity. For *plain* statuses, each entry has operations to get the current value of the status; for example, the *Topic* class has a **get\_inconsistent\_topic\_status()** operation. For *read* statuses, your application should use the **take()** operation on the *DataReader* to retrieve the newly arrived data that is indicated by **DATA\_AVAILABLE** and **DATA\_ON\_READER**.

Note that the two read communication statuses do not change independently. If data arrives for a *DataReader*, then its **DATA\_AVAILABLE** status changes. At the same time, the **DATA\_ON\_READERS** status changes for the *DataReader*'s *Subscriber*.

Both types of status have a **StatusChangedFlag**. This flag indicates whether that particular communication status has changed since the last time the status was read by the application. The way the

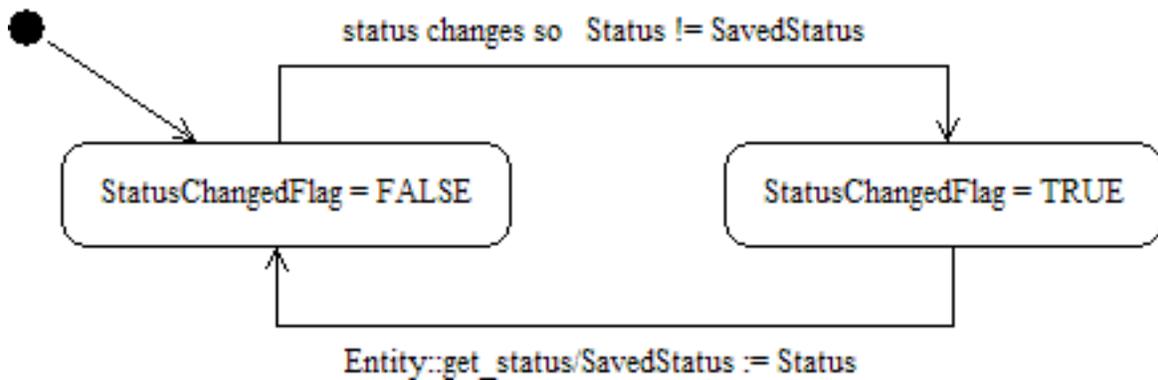

**StatusChangedFlag** is maintained is slightly different for the *plain* communication status and the *read* communication status, as described in the following sections:

- [15.7.1.1 Changes in Plain Communication Status below](#)
- [15.7.1.2 Changes in Read Communication Status on the next page](#)

### 15.7.1.1 Changes in Plain Communication Status

As seen in [Figure 15.2: Status Changes for Plain Communication Status below](#), for the plain communication status, the **StatusChangedFlag** flag is initially set to **FALSE**. It becomes **TRUE** whenever the plain communication status changes and is reset to **FALSE** each time the application accesses the plain communication status via the proper **get\_\*\_status()** operation.

Figure 15.2: Status Changes for Plain Communication Status

The communication status is also reset to **FALSE** whenever the associated listener operation is called, as the listener implicitly accesses the status which is passed as a parameter to the operation.

The fact that the status is reset prior to calling the listener means that if the application calls the **get\_\*\_status()** operation from inside the listener, it will see the status already reset.

An exception to this rule is when the associated listener is the 'nil' listener. The 'nil' listener is treated as a NO-OP and the act of calling the 'nil' listener does not reset the communication status. (See [15.8.1 Types of Listeners on page 47.](#))

For example, the value of the **StatusChangedFlag** associated with the **REQUESTED\_DEADLINE\_MISSED** status will become **TRUE** each time new deadline occurs (which increases the RequestedDeadlineMissed status' **total\_count** field). The value changes to **FALSE** when the application accesses the status via the corresponding **get\_requested\_deadline\_missed\_status()** operation on the proper Entity.

### 15.7.1.2 Changes in Read Communication Status

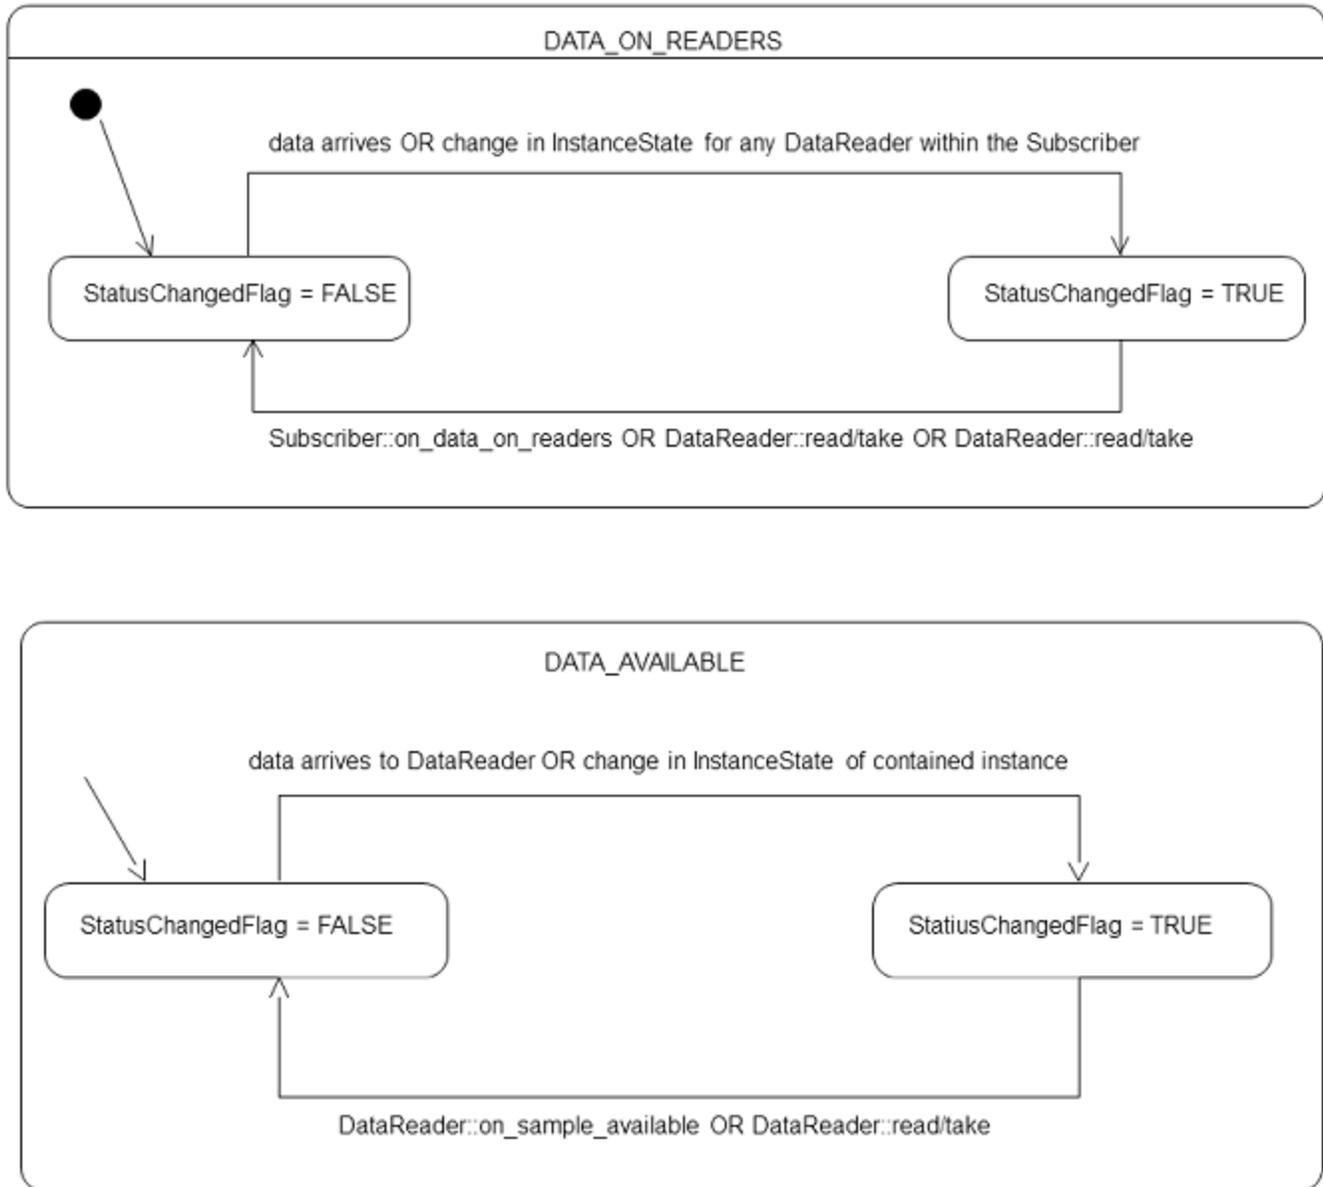

As seen in [Figure 15.3: Status Changes for Read Communication Status on the next page](#), for the read communication status, the `StatusChangedFlag` flag is initially set to `FALSE`. The `StatusChangedFlag` becomes `TRUE` when either a DDS data sample arrives or the `ViewStateKind`, `SampleStateKind`, or `InstanceStateKind` of any existing DDS sample changes for any reason other than a call to one of the read/take operations. Specifically, any of the following events will cause the `StatusChangedFlag` to become `TRUE`:

- The arrival of new data.
- A change in the `InstanceStateKind` of a contained instance. This can be caused by either:
  - Notification that an instance has been disposed by:
    - the *DataWriter* that owns it, if `OWNERSHIP = EXCLUSIVE`
    - or by any *DataWriter*, if `OWNERSHIP = SHARED`
  - The loss of liveness of the *DataWriter* of an instance for which there is no other *DataWriter*.
  - The arrival of the notification that an instance has been unregistered by the only *DataWriter* that is known to be writing the instance.

Depending on the **kind** of `StatusChangedFlag`, the flag transitions to `FALSE` (that is, the status is reset) as follows:

- The `DATA_AVAILABLE` `StatusChangedFlag` becomes `FALSE` when either `on_data_available()` is called or the read/take operation (or their variants) is called on the associated *DataReader*.
- The `DATA_ON_READERS` `StatusChangedFlag` becomes `FALSE` when any of the following occurs:
  - `on_data_on_readers()` is called.
  - `on_data_available()` is called on any *DataReader* belonging to the *Subscriber*.
  - `read()`, `take()`, or one of their variants is called on any *DataReader* belonging to the *Subscriber*.

Figure 15.3: Status Changes for Read Communication Status

## 15.7.2 Special Status-Handling Considerations for C

Some status structures contain variable-length sequences to store their values. In the C++, C# and Java languages, the memory allocation related to sequences are handled automatically through constructors/destructors and overloaded operators. However, the C language is limited in what it provides to automatically handle memory management. Thus, *Connex* provides functions and macros in C to initialize, copy, and finalize (free) status structures.

In the C language, it is not safe to use a status structure that has internal sequences declared in user code unless it has been initialized first. In addition, user code should always finalize a status structure to release any memory allocated for the sequences—even if the status structure was declared as a local, stack variable.

Thus, for a general status structure, *Connex* will provide:

- **DDS\_<STATUS>STATUS\_INITIALIZER** This is a macro that should be used when a **DDS\_<Status>Status** structure is declared in a C application.

```
struct DDS_<Status>Status status = DDS_<Status>Status_INITIALIZER;
```

- **DDS\_<Status>Status\_initialize()** This is a function that can be used to initialize a **DDS\_<Status>Status** structure instead of the macro above.

```
struct DDS_<Status>Status status;
DDS_<Status>Status_initialize(&status);
```

- **DDS\_<Status>Status\_finalize()** This is a function that should be used to finalize a **DDS\_<Status>Status** structure when the structure is no longer needed. It will free any memory allocated for sequences contained in the structure.

```
struct DDS_<Status>Status status = DDS_<Status>Status_INITIALIZER;
...
<use status>
...
// now done with Status
DDS_<Status>Status_finalize(&status);
```

- **DDS<Status>Status\_copy()** This is a function that can be used to copy one **DDS\_<Status>Status** structure to another. It will copy the sequences contained in the source structure and allocate memory for sequence elements if needed. In the code below, both **dstStatus** and **srcStatus** must have been initialized at some point earlier in the code.

```
DDS_<Status>Status_copy(&dstStatus, &srcStatus);
```

Note that many status structures do not have sequences internally. For those structures, you do not need to use the macro and methods provided above. However, they have still been created for your convenience.

## 15.8 Listeners

*Listeners* are triggered by changes in an entity's status. For instance, maybe *Connex* found a matching *DataReader* for a *DataWriter*, or new data has arrived for a *DataReader*.

You can use either *Listeners* or *WaitSets* to be notified of events. *WaitSets* block a thread until data is available. This is the safest way to get data, because it does not affect any middleware threads. In contrast, *Listeners* allow an application to be called back from a *Connex* thread. This provides better

latency than *WaitSets*, because the application can handle the event in the same thread that is generating the notification (so there is no time spent context-switching between threads).

There is also the possibility that notifications can be lost when using *WaitSets*, because most notifications contain a status update for only the most recent event. For example, imagine a system where a *DataReader* is trying to detect that *DataWriters* have lost liveliness. If two *DataWriters* lose liveliness at about the same, a listener that handles the **on\_liveliness\_changed** status will be called back once for each *DataWriter* that lost liveliness. When **on\_liveliness\_changed** is called back the first time, the *LivenessChangedStatus* will contain the handle for one of the *DataWriters*, and the second time the call-back is called it will contain the handle for the other *DataWriter*. However, if *WaitSets* are used and the *DataWriters* become not alive at about the same time, it's possible that by the time the *WaitSet* is notified that the first *DataWriter* has lost liveliness, the second one also loses liveliness, and the *LivenessChangedStatus* contains only the most recent *DataWriter* to lose liveliness.

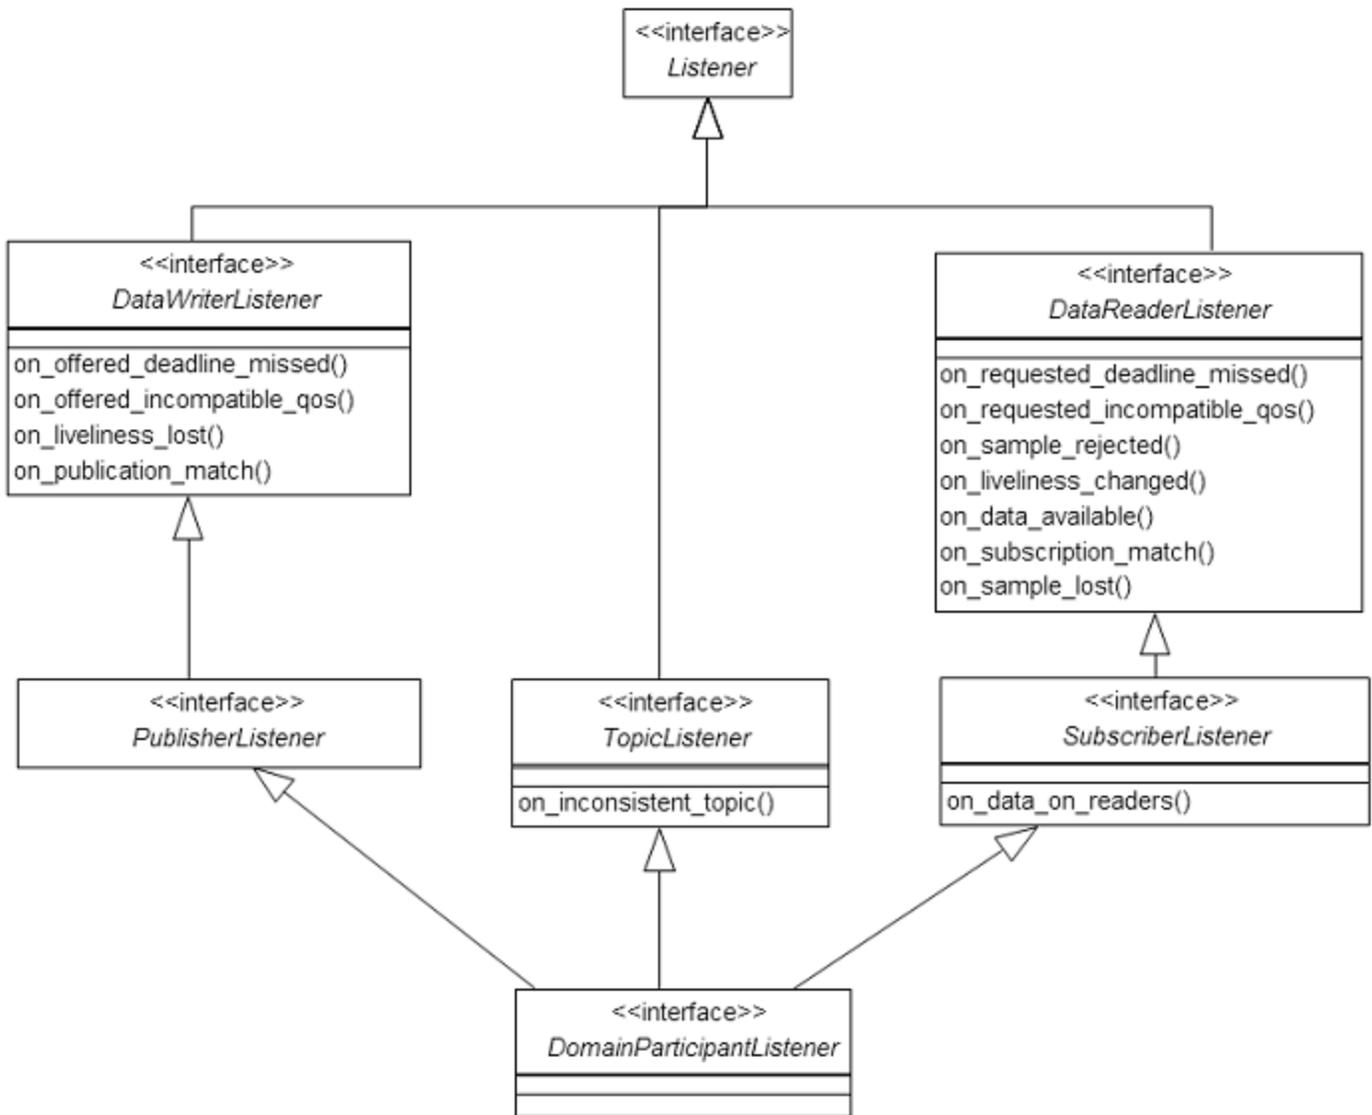

The danger of using *Listeners* is that they are called back from a *Connex* thread, so performing any slow processing in a *Listener* callback can degrade the performance of *Connex* (by causing lost data, lost liveliness, etc.).

This section describes *Listeners* and how to use them.

## 15.8.1 Types of Listeners

The *Listener* class is the abstract base class for all listeners. Each entity class (*DomainParticipant*, *Topic*, *Publisher*, *DataWriter*, *Subscriber*, and *DataReader*) has its own derived *Listener* class that add methods for handling entity-specific statuses. The hierarchy of *Listener* classes is presented in [Figure 15.4: Listener Class Hierarchy on the next page](#). The methods are called by an internal *Connex* thread when the corresponding status for the *Entity* changes value.

Figure 15.4: Listener Class Hierarchy

You can choose which changes in status will trigger a callback by installing a listener with a bit-mask. Bits in the mask correspond to different statuses. The bits that are true indicate that the listener will be called back when there are changes in the corresponding status.

You can specify a listener and set its bit-mask before or after you create an *Entity*:

#### During Entity creation:

```

DDS_StatusMask mask = DDS_REQUESTED_DEADLINE_MISSED_STATUS |
    DDS_DATA_AVAILABLE_STATUS;
datareader = subscriber->create_datareader(topic,
    DDS_DATAREADER_QOS_DEFAULT,
    listener, mask);
  
```

or afterwards:

```
DDS_StatusMask mask = DDS_REQUESTED_DEADLINE_MISSED_STATUS |
    DDS_DATA_AVAILABLE_STATUS;
datareader->set_listener(listener, mask);
```

As you can see in the above examples, there are two components involved when setting up listeners: the listener itself and the mask. The listener can be null, and the mask can have no bits set. [Table 15.3 Effect of Different Combinations of Listeners and Status Bit Masks](#) describes what happens when a status change occurs. See [15.8.5 Hierarchical Processing of Listeners on page 51](#) for more information.

**Table 15.3 Effect of Different Combinations of Listeners and Status Bit Masks**

	No Bits Set in Mask	Some/All Bits Set in Mask
Listener is Specified	<i>Connex</i> t finds the next most relevant listener for the changed status.	For the statuses that are enabled in the mask, the most relevant listener will be called. The 'statusChangedFlag' for the relevant status is reset.
Listener is NULL	<i>Connex</i> t behaves as if the listener is not installed and finds the next most relevant listener for that status.	<i>Connex</i> t behaves as if the listener callback is installed, but the callback is doing nothing. This is called a 'nil' listener.

## 15.8.2 Creating and Deleting Listeners

There is no factory for creating or deleting a *Listener*; use the natural means in each language binding (for example, “new” or “delete” in C++ or Java). For example:

```
class HelloWorldListener : public DDSDataReaderListener {
    virtual void on_data_available(DDSDataReader* reader);
};
void HelloWorldListener::on_data_available(DDSDataReader* reader)
{
    printf("received data\n");
}
// Create a Listener
HelloWorldListener *reader_listener = NULL;
reader_listener = new HelloWorldListener();
// Delete a Listener
delete reader_listener;
```

A listener cannot be deleted until the entity it is attached to has been deleted. For example, you must delete the *DataReader* before deleting the *DataReader*'s listener.

**Note:** Due to a thread-safety issue, the destruction of a *DomainParticipantListener* from an enabled *DomainParticipant* should be avoided—even if the *DomainParticipantListener* has been removed from the *DomainParticipant*. (This limitation does not affect the Java API.)

## 15.8.3 Special Considerations for Listeners in C

In C, a *Listener* is a structure with function pointers to the user callback routines. Often, you may only be interested in a subset of the statuses that can be monitored with the *Listener*. In those cases, you may

not set all of the functions pointers in a listener structure to a valid function. In that situation, we recommend that the unused, callback-function pointers are set to **NULL**. While setting the **DDS\_StatusMask** to enable only the callbacks for the statuses in which you are interested (and thus only enabling callbacks on the functions that actually exist) is safe, we still recommend that you clear all of the unused callback pointers in the *Listener* structure.

To help, in the C language, we provide a macro that can be used to initialize a Listener structure so that all of its callback pointers are set to **NULL**. For example

```
DDS_<Entity>Listener listener = DDS_<Entity>Listener_INITIALIZER;
// now only need to set the listener callback pointers for statuses // to be monitored
```

There is no need to do this in languages other than C.

## 15.8.4 Special Considerations for Listeners in Modern C++

In the Modern C++ API, the *Entity* constructors and **set\_listener** functions expect a **std::shared\_ptr**. The *Entity* keeps a reference to that **shared\_ptr** preventing its deletion at least until the *Entity* has been destroyed or the *Listener* reset.

In addition to each *Listener* base class (such as **dds::sub::DataReaderListener**), which contains a set of pure virtual functions, a class with a default implementation for each callback that does nothing is provided (such as **dds::sub::NoOpDataReaderListener**).

The following example shows how to create a *DataReaderListener*:

```
class HelloWorldListener : public dds::sub::NoOpDataReaderListener<HelloWorld> {
    void on_data_available(dds::sub::DataReader<HelloWorld> reader) override
    {
        auto samples = reader.take();
        std::cout << "Received " << samples.length() << " samples\n";
    }
};

void create_reader_with_listener()
{
    // ...
    auto reader_listener = std::make_shared<HelloWorldListener>();
    dds::sub::DataReader<HelloWorld> reader(subscriber, topic, qos, reader_listener);
    // ...
}
```

It is not recommended to keep a reference to the *Entity* as a member of a *Listener* class. Doing so creates a cycle between these two references preventing each other's destruction. If you do need to keep a reference, you must later reset the *Listener* or explicitly close the *Entity*.

## 15.8.5 Hierarchical Processing of Listeners

As seen in [Figure 15.4: Listener Class Hierarchy on page 48](#), *Listeners* for some *Entities* derive from the *Connex* *Listeners* for related *Entities*. This means that the derived *Listener* has all of the methods of its parent class. You can install *Listeners* at all levels of the object hierarchy. At the top is the *DomainParticipantListener*; only one can be installed in a *DomainParticipant*. Then every *Subscriber* and *Publisher* can have their own *Listener*. Finally, each *Topic*, *DataReader* and *DataWriter* can have their own listeners. All are optional.

Suppose, however, that an *Entity* does not install a *Listener*, or installs a *Listener* that does not have particular communication status selected in the bitmask. In this case, if/when that particular status changes for that *Entity*, the corresponding *Listener* for that *Entity's* parent is called. Status changes are “propagated” from child *Entity* to parent *Entity* until a *Listener* is found that is registered for that status. *Connex* will give up and drop the status-change event only if no *Listeners* have been installed in the object hierarchy to be called back for the specific status. This is true for *plain* communication statuses. *Read* communication statuses are handled somewhat differently, see [15.8.5.1 Processing Read Communication Statuses on the next page](#).

For example, suppose that *Connex* finds a matching *DataWriter* for a local *DataReader*. This event will change the **SUBSCRIPTION\_MATCHED** status. So the local *DataReader* object is checked to see if the application has installed a listener that handles the **SUBSCRIPTION\_MATCH** status. If not, the *Subscriber* that created the *DataReader* is checked to see if it has a listener installed that handles the same event. If not, the *DomainParticipant* is checked. The *DomainParticipantListener* methods are called only if none of the descendent *Entities* of the *DomainParticipant* have listeners that handle the particular status that has changed. Again, all listeners are optional. Your application does not have to handle any communication statuses.

[Table 15.4 Listener Callback Functions](#) lists the callback functions that are available for each *Entity's* status listener.

Table 15.4 Listener Callback Functions

Entity Listener for:		Callback Functions
DomainParticipants	Topics	on_inconsistent_topic()
	Publishers and DataWriters	on_liveliness_lost()
		on_offered_deadline_missed()
		on_offered_incompatible_qos()
		on_publication_matched()
		on_reliable_reader_activity_changed()
		on_reliable_writer_cache_changed()
	Subscribers	on_data_on_readers()
	Subscribers and DataReaders	on_data_available
		on_liveliness_changed()
		on_requested_deadline_missed()
		on_requested_incompatible_qos()
		on_sample_lost()
		on_sample_rejected()
		on_subscription_matched()

### 15.8.5.1 Processing Read Communication Statuses

The processing of the **DATA\_ON\_READERS** and **DATA\_AVAILABLE** read communication statuses are handled slightly differently since, when new data arrives for a *DataReader*, both statuses change simultaneously. However, only one, if any, *Listener* will be called to handle the event.

If there is a *Listener* installed to handle the **DATA\_ON\_READERS** status in the *DataReader's Subscriber* or in the *DomainParticipant*, then that *Listener's on\_data\_on\_readers()* function will be called back. The *DataReaderListener's on\_data\_available()* function is called only if the **DATA\_ON\_READERS** status is not handle by any relevant listeners.

This can be useful if you have generic processing to do whenever new data arrives for any *DataReader*. You can execute the generic code in the **on\_data\_on\_readers()** method, and then dispatch the processing of the actual data to the specific *DataReaderListener's on\_data\_available()* function by calling the **notify\_datareaders()** method on the *Subscriber*.

For example:

```
void on_data_on_readers (DDSSubscriber *subscriber)
{
    // Do some general processing that needs to be done
}
```

```

// whenever new data arrives, but is independent of
// any particular DataReader
< generic processing code here >

// Now dispatch the actual processing of the data
// to the specific DataReader for which the data
// was received
subscriber->notify_datareaders();
}

```

## 15.8.6 Operations Allowed within Listener Callbacks

Due to the potential for deadlock, some *Connex* APIs should not be invoked within the functions of listener callbacks. Exactly which *Connex* APIs are restricted depends on the *Entity* upon which the *Listener* is installed, as well as the configuration of ‘Exclusive Areas,’ as discussed in [15.8.8 Exclusive Areas \(EAs\) on the next page](#).

Please read and understand [15.8.8 Exclusive Areas \(EAs\) on the next page](#) and [15.8.8.1 Restricted Operations in Listener Callbacks on page 57](#) to ensure that the calls made from your *Listeners* are allowed and will not cause potential deadlock situations.

## 15.8.7 Best Practices with Listeners

Note: All the issues described below can be avoided by using a *Waitset*.

- Avoid blocking or performing a lot of processing in Listener callbacks

*Listeners* are invoked by internal threads that perform critical functions within the middleware and need to run in a timely manner (see [Part 11: Connex Threading Model \(on page 1180\)](#)). By default, *Connex* creates a few threads to use to receive data and only a single thread to handle periodic events.

Because of this, user applications installing *Listeners* should never block in a *Listener* callback. There are several negative consequences of blocking in a listener callback:

- The application may lose data for the *DataReader* the listener is installed on, because the receive thread is not removing it from the socket buffer and it gets overwritten (see [Chapter 66 Receive Threads on page 1187](#)).
- The application may receive strictly reliable data with a delay, because the receive thread is not removing it from the socket buffer and if it gets overwritten it must be re-sent.
- The application may lose or delay data for other *DataReaders*, because by default all *DataReaders* created with the same *DomainParticipant* share the same threads.
- The application may not be notified of periodic events on time (see [Chapter 65 Event Thread on page 1185](#)).

If the application needs to make a blocking call when data is available, or when another event occurs, the application should use a *WaitSet*. (see [15.9 Conditions and WaitSets on page 59](#)).

- Avoid taking application mutexes/semaphores in *Listener* callbacks

Taking application mutexes/semaphores within a *Listener* callback may lead to unexpected deadlock scenarios. When a *Listener* callback is invoked, the EA (Exclusive Area) of the Entity 'E' to which the callback applies is taken by the middleware. If the application takes an application mutex 'M' within a critical section in which the application makes DDS calls affecting 'E', this may lead to following deadlock:

The middleware thread is within the entity EA trying to acquire the mutex 'M'. At the same time, the application thread has acquired 'M' and is blocked trying to acquire the entity EA.

- Do not write data with a *DataWriter* within the **on\_data\_available()** callback

Avoid writing data with a *DataWriter* within the *DataReaderListener*'s **on\_data\_available()** callback. If the write operation blocks because e.g. the send window is full, this will lead to a deadlock.

- Do not call **wait\_for\_acknowledgements()** within the **on\_data\_available()** callback

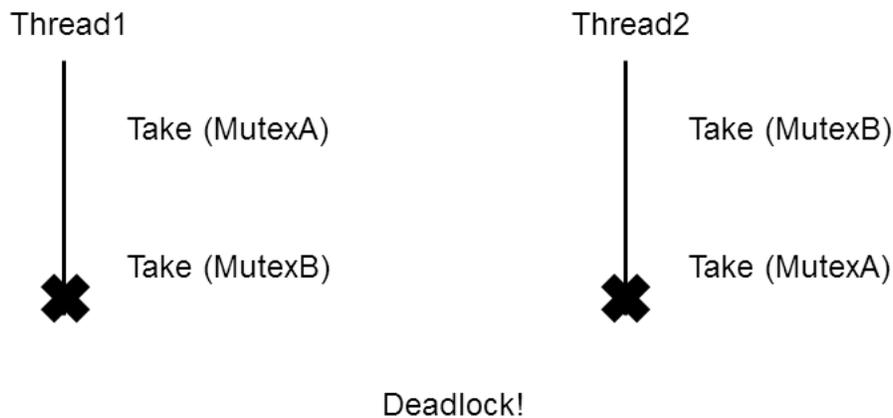

Do not call the *DataWriter*'s **wait\_for\_acknowledgments()** within the *DataReaderListener*'s **on\_data\_available()** callback. This will lead to deadlock.

## 15.8.8 Exclusive Areas (EAs)

Listener callbacks are invoked by internal *Connex* threads. To prevent undesirable, multi-threaded interaction, the internal threads may take and hold semaphores (mutexes) used for mutual exclusion. In your listener callbacks, you may want to invoke functions provided by the *Connex* API. Internally, those *Connex* functions also may take mutexes to prevent errors due to multi-threaded access to critical data or operations.

Once there are multiple mutexes to protect different critical regions, the possibility for deadlock exists. Consider [Figure 15.5: Multiple Mutexes Leading to a Deadlock Condition on the next page](#)'s scenario, in which there are two threads and two mutexes.

Figure 15.5: Multiple Mutexes Leading to a Deadlock Condition

*Thread1 takes MutexA while simultaneously Thread2 takes MutexB. Then, Thread1 takes MutexB and simultaneously Thread2 takes MutexA. Now both threads are blocked since they hold a mutex that the other thread is trying to take. This is a deadlock condition.*

While the probability of entering the deadlock situation in [Figure 15.5: Multiple Mutexes Leading to a Deadlock Condition above](#) depends on execution timing, when there are multiple threads and multiple mutexes, care must be taken in writing code to prevent those situations from existing in the first place. *Connex* has been carefully created and analyzed so that we know our threads internally are safe from deadlock interactions.

However, when *Connex* threads that are holding mutexes call user code in listeners, it is possible for user code to inadvertently cause the threads to deadlock if *Connex* APIs that try to take other mutexes are invoked. To help you avoid this situation, RTI has defined a concept known as *Exclusive Areas*, some restrictions regarding the use of *Connex* APIs within user callback code, and a QoS policy that allows you to configure *Exclusive Areas*.

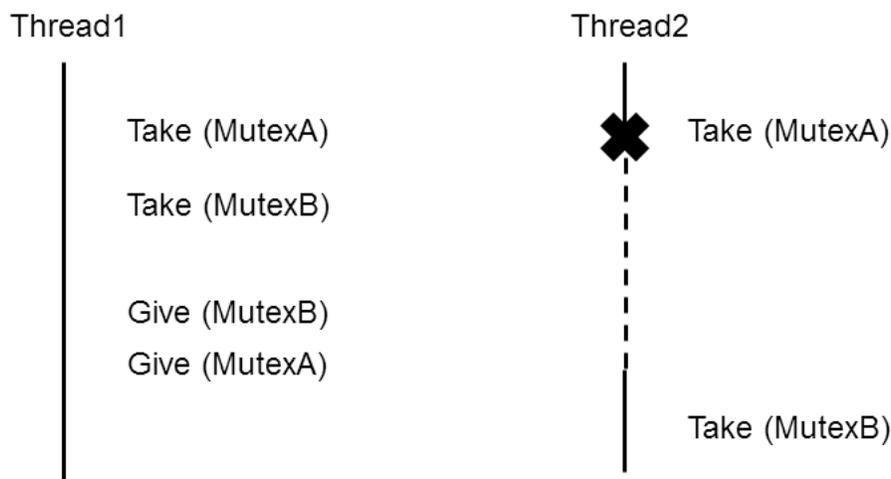

*Connex* uses *Exclusive Areas* (EAs) to encapsulate mutexes and critical regions. Only one thread at a time can be executing code within an EA. The formal definition of EAs and their implementation ensures safety from deadlock and efficient entering and exiting of EAs. While every *Entity* created by *Connex* has an associated EA, EAs may be shared among several *Entities*. A thread is automatically in the entity's EA when it is calling the entity's listener.

*Connex* allows you to configure all the *Entities* within an application in a single DDS domain to share a single *Exclusive Area*. This would greatly restrict the concurrency of thread execution within *Connex*'s multi-threaded core. However, doing so would release all restrictions on using *Connex* APIs within your callback code.

You may also have the best of both worlds by configuring a set of *Entities* to share a global EA and others to have their own. For the *Entities* that have their own EAs, the types of *Connex* operations that you can call from the *Entity*'s callback are restricted.

To understand why the general EA framework limits the operations that can be called in an EA, consider a modification to the example previously presented in [Figure 15.5: Multiple Mutexes Leading to a Deadlock Condition on the previous page](#). Suppose we create a rule that is followed when we write our code. “For all situations in which a thread has to take multiple mutexes, we write our code so that the mutexes are always taken in the same order.” Following the rule will ensure us that the code we write cannot enter a deadlock situation due to the taking of the mutexes, see [Figure 15.6: Taking Multiple Mutexes in a Specific Order to Eliminate Deadlock below](#).

Figure 15.6: Taking Multiple Mutexes in a Specific Order to Eliminate Deadlock

*By creating an order in which multiple mutexes are taken, you can guarantee that no deadlock situation will arise. In this case, if a thread must take both MutexA and MutexB, we write our code so that in those cases MutexA is always taken before MutexB.*

*Connex* defines an ordering of the mutexes it creates. Generally speaking, there are three ordered levels of Exclusive Areas:

- **ParticipantEA**

There is only one ParticipantEA per participant. The creation and deletion of all *Entities* (**create\_xxx()**, **delete\_xxx()**) take the ParticipantEA. In addition, the **enable()** method for an *Entity* and the setting of the *Entity*'s QoS, **set\_qos()**, also take the ParticipantEA. There are other functions that take the ParticipantEA: **get\_discovered\_participants()**, **get\_publishers()**, **get\_subscribers()**, **get\_discovered\_topics()**, **ignore\_participant()**, **ignore\_topic()**, **ignore\_publication()**, **ignore\_subscription()**, **remove\_peer()**, and **register\_type()**.

- **SubscriberEA**

This EA is created on a per-*Subscriber* basis by default. You can assume that the methods of a *Subscriber* will take the SubscriberEA. In addition, the *DataReaders* created by a *Subscriber* share the EA of its parent. This means that the methods of a *DataReader* (including **take()** and **read()**) will take the EA of its *Subscriber*. Therefore, **operations on DataReaders of the same Subscriber, will be serialized**, even when invoked from multiple concurrent application threads. As mentioned, the **enable()** and **set\_qos()** methods of both *Subscribers* and *DataReaders* will take the ParticipantEA. The same is true for the **create\_datareader()** and **delete\_datareader()** methods of the *Subscriber*.

- **PublisherEA**

This EA is created on a per-*Publisher* basis by default. You can assume that the methods of a *Publisher* will take the PublisherEA. In addition, the *DataWriters* created by a *Publisher* share the EA of its parent. This means that the methods of a *DataWriter* including **write()** will take the EA of its *Publisher*. Therefore, **operations on DataWriters of the same Publisher will be serialized**, even when invoked from multiple concurrent application threads. As mentioned, the **enable()** and **set\_qos()** methods of both *Publishers* and *DataWriters* will take the ParticipantEA, as well as the **create\_datawriter()** and **delete\_datawriter()** methods of the *Publisher*.

In addition, you should also be aware that:

- The three EA levels are ordered in the following manner:  
ParticipantEA < SubscriberEA < PublisherEA
- When executing user code in a listener callback of an *Entity*, the internal *Connex* thread is already in the EA of that *Entity* or used by that *Entity*.
- If a thread is in an EA, it can call methods associated with either a higher EA level or that share the *same* EA. It cannot call methods associated with a lower EA level *nor* ones that use a *different* EA at the same level.

### 15.8.8.1 Restricted Operations in Listener Callbacks

Based on the background and rules provided in [15.8.8 Exclusive Areas \(EAs\) on page 54](#), this section describes how EAs restrict you from using various *Connex* APIs from within the Listener callbacks of different *Entities*. Reader callbacks take the SubscriberEA. Writer callbacks take the PublisherEA. DomainParticipant callbacks take the ParticipantEA.

These restrictions do not apply to builtin topic listener callbacks.

By default, each *Publisher* and *Subscriber* creates and uses its own EA, and shares it with its children *DataWriters* and *DataReaders*, respectively. In that case:

Within a *DataWriter/DataReader's* Listener callback, do not:

- Create any *Entities*
- Delete any *Entities*
- Enable any *Entities*
- Set QoS on any *Entities*

Within a *Subscriber/DataReader's Listener* callback, do not call any operations on:

- Other *Subscribers*
- *DataReaders* that belong to other *Subscribers*
- *Publishers/DataWriters* that have been configured to use the ParticipantEA (see below)

Within a *Publisher/DataWriter Listener* callback, do not call any operations on:

- Other *Publishers*
- *DataWriters* that belong to other *Publishers*
- Any *Subscribers*
- Any *DataReaders*

*Connex* will enforce the rules to avoid deadlock, and any attempt to call an illegal method from within a *Listener* callback will return `DDS_RETCODE_ILLEGAL_OPERATION`.

However, as previously mentioned, if you are willing to trade-off concurrency for flexibility, you may configure individual *Publishers* and *Subscribers* (and thus their *DataWriters* and *DataReaders*) to share the EA of their participant. In the limit, only a single ParticipantEA is shared among all *Entities*. When doing so, the restrictions above are lifted at a cost of greatly reduced concurrency. You may create/delete/enable/set\_qos's and generally call all of the methods of any other entity in the *Listener* callbacks of *Entities* that share the ParticipantEA.

Use the [46.3 EXCLUSIVE\\_AREA QoS Policy \(DDS Extension\) on page 746](#) of the *Publisher* or *Subscriber* to set whether or not to use a shared exclusive area. By default, *Publishers* and *Subscribers* will create and use their own individual EAs. You can configure a subset of the *Publishers* and *Subscribers* to share the ParticipantEA if you need the *Listeners* associated with those *Entities* or child *Entities* to be able to call any of the restricted methods listed above.

Regardless of how the `EXCLUSIVE_AREA` QoS Policy is set, the following operations are never allowed in any *Listener* callback:

- Destruction of the entity to which the *Listener* is attached. For instance, a *DataWriter/DataReader Listener* callback must not destroy its *DataWriter/DataReader*.

- Within the *TopicListener* callback, you cannot call any operations on *DataReaders*, *DataWriters*, *Publishers*, *Subscribers* or *DomainParticipants*.

## 15.9 Conditions and WaitSets

*Conditions* and *WaitSets* provide another way for *Connex*t to communicate status changes (including the arrival of data) to your application. While a *Listener* is used to provide a callback for asynchronous access, *Conditions* and *WaitSets* provide synchronous data access. In other words, *Listeners* are notification-based and *Conditions* are wait-based.

A *WaitSet* allows an application to wait until one or more attached *Conditions* becomes true (or until a timeout expires).

Briefly, your application can create a *WaitSet*, attach one or more *Conditions* to it, then call the *WaitSet*'s **wait()** operation. The **wait()** blocks until one or more of the *WaitSet*'s attached *Conditions* becomes TRUE.

A *Condition* has a **trigger\_value** that can be TRUE or FALSE. You can retrieve the current value by calling the *Condition*'s only operation, **get\_trigger\_value()**.

There are three kinds of *Conditions*. A *Condition* is a root class for all the conditions that may be attached to a *WaitSet*. This basic class is specialized in three classes:

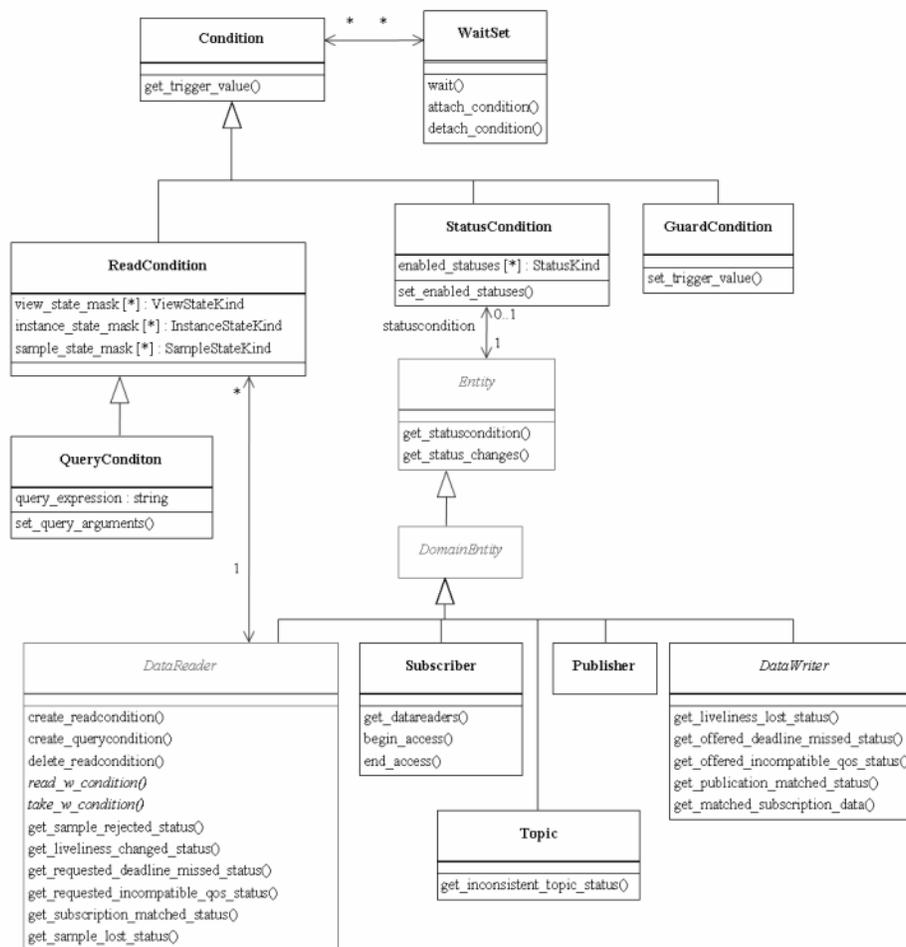

- [15.9.6 GuardConditions on page 66](#) are created by your application. Each *GuardCondition* has a single, user-settable, boolean **trigger\_value**. Your application can manually trigger the *GuardCondition* by calling **set\_trigger\_value()**. *Connex*t does not trigger or clear this type of condition—it is completely controlled by your application.
- [15.9.7 ReadConditions and QueryConditions on page 66](#) are created by your application, but triggered by *Connex*t. *ReadConditions* provide a way for you to specify the DDS data samples that you want to wait for, by indicating the desired sample-states, view-states, and instance-states<sup>1</sup>.
- [15.9.8 StatusConditions on page 69](#) are created automatically by *Connex*t, one for each *Entity*. A *StatusCondition* is triggered by *Connex*t when there is a change to any of that *Entity*'s enabled statuses.

[Figure 15.7: Conditions and WaitSets on the next page](#) shows the relationship between these objects and other *Entities* in the system.

---

<sup>1</sup>These states are described in [41.6 The SampleInfo Structure on page 676](#).

Figure 15.7: Conditions and WaitSets

A *WaitSet* can be associated with more than one *Entity* (including multiple *DomainParticipants*). It can be used to wait on *Conditions* associated with different *DomainParticipants*. A *WaitSet* can only be in use by one application thread at a time.

## 15.9.1 Creating and Deleting WaitSets

There is no factory for creating or deleting a *WaitSet*; use the natural means in each language binding (for example, “new” or “delete” in C++ or Java).

There are two ways to create a *WaitSet*—with or without specifying *WaitSet* properties (**DDS\_**[WaitSetProperty\\_t](#), described in [Table 15.5 WaitSet Properties \(DDS\\_](#)[WaitSet\\_Property\\_t](#)[\)](#)). [15.9.3 Waiting for Conditions on page 62](#) describes how the properties are used.

Table 15.5 WaitSet Properties (DDS\_WaitSet\_Property\_t)

Type	Field Name	Description
long	max_event_count	Maximum number of trigger events to cause a <i>WaitSet</i> to wake up.
DDS_Duration_t	max_event_delay	Maximum delay from occurrence of first trigger event to cause a <i>WaitSet</i> to wake up. This value should reflect the maximum acceptable latency increase (time delay from occurrence of the event to waking up the <i>WaitSet</i> ) incurred as a result of waiting for additional events before waking up the <i>WaitSet</i> .

To create a *WaitSet* with default behavior:

```
WaitSet* waitset = new WaitSet();
```

To create a *WaitSet* with properties:

```
DDS_WaitSetProperty_t prop;
Prop.max_event_count = 5;
DDSWaitSet* waitset = new DDSWaitSet(prop);
```

To delete a *WaitSet*:

```
delete waitset;
```

## 15.9.2 WaitSet Operations

*WaitSets* have only a few operations, as listed in [Table 15.6 WaitSet Operations](#). For details, see the API Reference HTML documentation.

Table 15.6 WaitSet Operations

Operation	Description
attach_condition	Attaches a <i>Condition</i> to this <i>WaitSet</i> . You may attach a <i>Condition</i> to a <i>WaitSet</i> that is currently being waited upon (via the <b>wait()</b> operation). In this case, if the <i>Condition</i> has a <b>trigger_value</b> of TRUE, then attaching the <i>Condition</i> will unblock the <i>WaitSet</i> . Adding a <i>Condition</i> that is already attached to the <i>WaitSet</i> has no effect. If the <i>Condition</i> cannot be attached, <i>Connnext</i> will return an OUT_OF_RESOURCES error code.
detach_condition	Detaches a <i>Condition</i> from the <i>WaitSet</i> . Attempting to detach a <i>Condition</i> that is not to attached the <i>WaitSet</i> will result in a PRECONDITION_NOT_MET error code.
wait	Blocks execution of the thread until one or more attached <i>Conditions</i> becomes true, or until a user-specified timeout expires. See <a href="#">15.9.3 Waiting for Conditions on the next page</a> .
dispatch	(Modern C++ API only) Blocks execution of the thread until one or more attached <i>Conditions</i> becomes true, or until a user-specified timeout expires. Then it calls the handlers attached to the active conditions and returns. For more information see the API Reference HTML documentation for the DDS Modern C++ API (Modules, Infrastructure Module, Conditions and WaitSets).

**Table 15.6 WaitSet Operations**

Operation	Description
get_conditions	Retrieves a list of attached <i>Conditions</i> .
get_property	Retrieves the DDS_WaitSetProperty_t structure of the associated <i>WaitSet</i> .
set_property	Sets the DDS_WaitSetProperty_t structure, to configure the associated <i>WaitSet</i> to return after one or more trigger events have occurred.

### 15.9.3 Waiting for Conditions

The *WaitSet*'s **wait()** operation allows an application thread to wait for any of the attached *Conditions* to trigger (become TRUE).

If any of the attached *Conditions* are already TRUE when **wait()** is called, it returns immediately.

If none of the attached *Conditions* are already TRUE, **wait()** blocks—suspending the calling thread. The waiting behavior depends on whether or not properties were set when the *WaitSet* was created:

- **If properties are not specified when the *WaitSet* is created:**

The *WaitSet* will wake up as soon as a trigger event occurs (that is, when an attached *Condition* becomes true). This is the default behavior if properties are not specified.

This 'immediate wake-up' behavior is optimal if you want to minimize latency (to wake up and process the data or event as soon as possible). However, "waking up" involves a context switch—the operating system must signal and schedule the thread that is waiting on the *WaitSet*. A context switch consumes significant CPU and therefore waking up on each data update is not optimal in situations where the application needs to maximize throughput (the number of messages processed per second). This is especially true if the receiver is CPU limited.

- **If properties are specified when the *WaitSet* is created:**

The properties configure the waiting behavior of a *WaitSet*. If no conditions are true at the time of the call to **wait**, the *WaitSet* will wait for (a) **max\_event\_count** trigger events to occur, (b) up to **max\_event\_delay** time from the occurrence of the first trigger event, or (c) up to the timeout maximum wait duration specified in the call to **wait()**. (**Note:** The resolution of the timeout period is constrained by the resolution of the system clock.)

If **wait()** does not timeout, it returns a list of the attached *Conditions* that became TRUE and therefore unblocked the wait.

If **wait()** does timeout, it returns TIMEOUT and an empty list of *Conditions*.

Only one application thread can be waiting on the same *WaitSet*. If **wait()** is called on a *WaitSet* that already has a thread blocking on it, the operation will immediately return `PRECONDITION_NOT_MET`.

If you detach a *Condition* from a *Waitset* that is currently in a wait state (that is, you are waiting on it), **wait()** may return `OK` and an empty sequence of conditions.

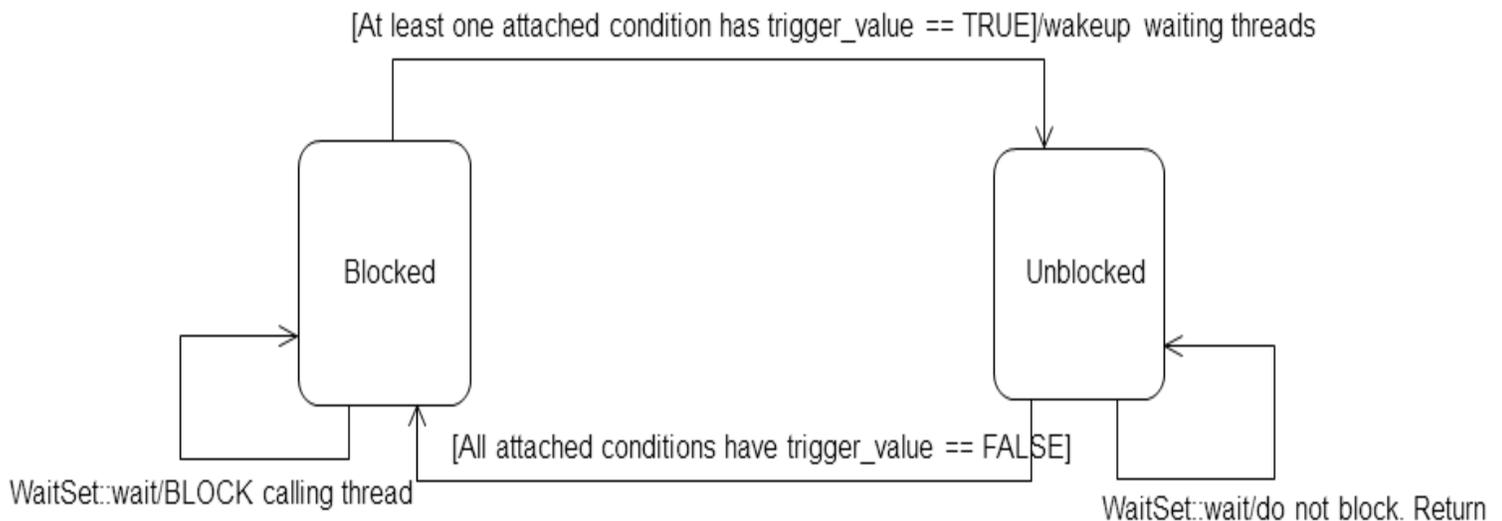

### 15.9.3.1 How WaitSets Block

The blocking behavior of the *WaitSet* is illustrated in [Figure 15.8: WaitSet Blocking Behavior](#) below. The result of a **wait()** operation depends on the state of the *WaitSet*, which in turn depends on whether at least one attached *Condition* has a **trigger\_value** of `TRUE`.

If the **wait()** operation is called on a *WaitSet* with state `BLOCKED`, it will block the calling thread. If **wait()** is called on a *WaitSet* with state `UNBLOCKED`, it will return immediately.

When the *WaitSet* transitions from `BLOCKED` to `UNBLOCKED`, it wakes up the thread (if there is one) that had called **wait()** on it. There is no implied “event queuing” in the awakening of a *WaitSet*. That is, if several *Conditions* attached to the *WaitSet* have their **trigger\_value** transition to true in sequence, *Connex* will only unblock the *WaitSet* once.

Figure 15.8: WaitSet Blocking Behavior

## 15.9.4 Processing Triggered Conditions—What to do when Wait() Returns

When **wait()** returns, it provides a list of the attached *Condition* objects that have a **trigger\_value** of true. Your application can use this list to do the following for each *Condition* in the returned list:

- If it is a *StatusCondition*:
  - First, call `get_status_changes()` to see what status changed.
  - If the status changes refer to plain communication status: call `get_<communication_status>()` on the relevant *Entity*.
  - If the status changes refer to `DATA_ON_READERS`<sup>1</sup>: call `get_datareaders()` on the relevant *Subscriber*.
  - If the status changes refer to `DATA_AVAILABLE`: call `read()` or `take()` on the relevant *DataReader*.
- If it is a *ReadCondition* or a *QueryCondition*: You may want to call `read_w_condition()` or `take_w_condition()` on the *DataReader*, with the *ReadCondition* as a parameter (see [41.3.6 read\\_w\\_condition and take\\_w\\_condition on page 672](#)).

Note that this is just a suggestion, you do not have to use the “w\_condition” operations (or any read/take operations, for that matter) simply because you used a *WaitSet*. The “w\_condition” operations are just a convenient way to use the same status masks that were set on the *ReadCondition* or *QueryCondition*.

- If it is a *GuardCondition*: check to see which *GuardCondition* changed, then react accordingly. Recall that *GuardConditions* are completely controlled by your application.

See [15.9.5 Conditions and WaitSet Example below](#) to see how to determine which of the attached *Conditions* is in the returned list.

## 15.9.5 Conditions and WaitSet Example

This example creates a *WaitSet* and then waits for one or more attached *Conditions* to become true.

```
// Create a WaitSet
WaitSet* waitset = new WaitSet();
// Attach Conditions
DDSCondition* cond1 = ...;
DDSCondition* cond2 = entity->get_statuscondition();
DDSCondition* cond3 = reader->create_readcondition(
    DDS_NOT_READ_SAMPLE_STATE,
    DDS_ANY_VIEW_STATE,
    DDS_ANY_INSTANCE_STATE);
DDSCondition* cond4 = new DDSGuardCondition();
DDSCondition* cond5 = ...;
DDS_ReturnCode_t retcode;

retcode = waitset->attach_condition(cond1);
if (retcode != DDS_RETCODE_OK) {
    // ... error
}
```

<sup>1</sup>And then read/take on the returned *DataReader* objects.

```

retcode = waitset->attach_condition(cond2);
if (retcode != DDS_RETCODE_OK) {
    // ... error
}
retcode = waitset->attach_condition(cond3);
if (retcode != DDS_RETCODE_OK) {
    // ... error
}
retcode = waitset->attach_condition(cond4);
if (retcode != DDS_RETCODE_OK) {
    // ... error
}
retcode = waitset->attach_condition(cond5);
if (retcode != DDS_RETCODE_OK) {
    // ... error
}
// Wait for a condition to trigger or timeout
DDS_Duration_t timeout = { 0, 1000000 }; // 1ms
DDSConditionSeq active_conditions; // holder for active conditions
bool is_cond1_triggered = false;
bool is_cond2_triggered = false;
DDS_ReturnCode_t retcode;

retcode = waitset->wait(active_conditions, timeout);
if (retcode == DDS_RETCODE_TIMEOUT) {
    // handle timeout
    printf("Wait timed out. No conditions were triggered.\n");
}
else if (retcode != DDS_RETCODE_OK) {
    // ... check for cause of failure
} else {
    // success
    if (active_conditions.length() == 0) {
        printf("Wait timed out!! No conditions triggered.\n");
    } else
        // check if "cond1" or "cond2" are triggered:
        for(i = 0; i < active_conditions.length(); ++i) {
            if (active_conditions[i] == cond1) {
                printf("Cond1 was triggered!");
                is_cond1_triggered = true;
            }
            if (active_conditions[i] == cond2) {
                printf("Cond2 was triggered!");
                is_cond2_triggered = true;
            }
            if (is_cond1_triggered && is_cond2_triggered) {
                break;
            }
        }
}
}
if (is_cond1_triggered) {
    // ... do something because "cond1" was triggered ...
}
if (is_cond2_triggered) {
    // ... do something because "cond2" was triggered ...
}

```

```
// Delete the waitset
delete waitset;
waitset = NULL;
```

## 15.9.6 GuardConditions

*GuardConditions* are created by your application. *GuardConditions* provide a way for your application to manually awaken a *WaitSet*. Like all *Conditions*, it has a single boolean **trigger\_value**. Your application can manually trigger the *GuardCondition* by calling **set\_trigger\_value()**.

*Connex* does not trigger or clear this type of condition—it is completely controlled by your application.

A *GuardCondition* has no factory. It is created as an object directly by the natural means in each language binding (e.g., using “new” in C++ or Java). For example:

```
// Create a Guard Condition
Condition* my_guard_condition = new GuardCondition();
// Delete a Guard Condition
delete my_guard_condition;
```

When first created, the **trigger\_value** is FALSE.

A *GuardCondition* has only two operations, **get\_trigger\_value()** and **set\_trigger\_value()**.

When your application calls **set\_trigger\_value(DDS\_BOOLEAN\_TRUE)**, *Connex* will awaken any *WaitSet* to which the *GuardCondition* is attached.

## 15.9.7 ReadConditions and QueryConditions

*ReadConditions* are created by your application, but triggered by *Connex*. *ReadConditions* provide a way for you to specify the DDS data samples that you want to wait for, by indicating the desired sample-states, view-states, and instance-states (see [19.1 Instance States on page 258](#)). Then *Connex* will trigger the *ReadCondition* when suitable DDS samples are available.

A *QueryCondition* is a special *ReadCondition* that allows you to specify a query expression and parameters, so you can filter on the locally available (already received) data. *QueryConditions* use the same SQL-based filtering syntax as *ContentFilteredTopics* for query expressions, parameters, etc. Unlike *ContentFilteredTopics*, *QueryConditions* are applied to data already received, so they do not affect the reception of data.

Multiple mask combinations can be associated with a single content filter. This is important because the maximum number of content filters that may be created per *DataReader* is 32, but more than 32 *QueryConditions* may be created per *DataReader*, if they are different mask-combinations of the same content filter.

*ReadConditions* and *QueryConditions* are created by using the *DataReader*’s **create\_readcondition()** and **create\_querycondition()** operations. For example:

```

DDSReadCondition* my_read_condition =
    reader->create_readcondition(
        DDS_NOT_READ_SAMPLE_STATE,
        DDS_ANY_VIEW_STATE,
        DDS_ANY_INSTANCE_STATE);
DDSQueryCondition* my_query_condition =
    reader->create_querycondition(
        DDS_NOT_READ_SAMPLE_STATE,
        DDS_ANY_VIEW_STATE,
        DDS_ANY_INSTANCE_STATE,
        query_expression,
        query_parameters);

```

You can also use the alternative *DataReader* operations, **create\_readcondition\_w\_params()** and **create\_querycondition\_w\_params()**, which perform the same action as **create\_readcondition()** and **create\_querycondition()**, but allow the application to explicitly set the masks in the `DDS_ReadConditionParams` and `DDS_QueryConditionParams` structures (see [Table 15.8 DDS\\_ReadConditionParams](#) and [Table 15.9 DDS\\_QueryConditionParams](#)).

In addition, **create\_readcondition\_w\_params()** and **create\_querycondition\_w\_params()** allow selecting between *TopicQuery* samples and *LIVE* samples (see [Topic Queries \(Chapter 60 on page 1142\)](#)).

A *DataReader* can have multiple attached *ReadConditions* and *QueryConditions*. A *ReadCondition* or *QueryCondition* may only be attached to one *DataReader*.

To delete a *ReadCondition* or *QueryCondition*, use the *DataReader*'s **delete\_readcondition()** operation:

```

DDS_ReturnCode_t delete_readcondition (DDSReadCondition *condition)

```

After a *ReadCondition* is triggered, use the *FooDataReader*'s read/take “with condition” operations (see [41.3.6 read\\_w\\_condition and take\\_w\\_condition on page 672](#)) to access the DDS samples.

[Table 15.7 ReadCondition and QueryCondition Operations](#) lists the operations available on *ReadConditions*.

Table 15.7 ReadCondition and QueryCondition Operations

Operation	Description
get_datareader	Returns the <i>DataReader</i> to which the <i>ReadCondition</i> or <i>QueryCondition</i> is attached.
get_instance_state_mask	Returns the instance states that were specified when the <i>ReadCondition</i> or <i>QueryCondition</i> was created. These are the DDS sample's instance states that <i>Connex</i> checks to determine whether or not to trigger the <i>ReadCondition</i> or <i>QueryCondition</i> .
get_sample_state_mask	Returns the sample-states that were specified when the <i>ReadCondition</i> or <i>QueryCondition</i> was created. These are the sample states that <i>Connex</i> checks to determine whether or not to trigger the <i>ReadCondition</i> or <i>QueryCondition</i> .
get_view_state_mask	Returns the view-states that were specified when the <i>ReadCondition</i> or <i>QueryCondition</i> was created. These are the view states that <i>Connex</i> checks to determine whether or not to trigger the <i>ReadCondition</i> or <i>QueryCondition</i> .
get_stream_kind_mask	Retrieves the stream kind mask for the condition.

Table 15.8 DDS\_ReadConditionParams

Type	Field Name	Description
DDS_SampleStateMask	sample_states	Sample state of the data samples that are of interest.
DDS_ViewStateMask	view_states	View state of the data samples that are of interest.
DDS_InstanceStateMask	instance_states	Instance state of the data samples that are of interest.
DDS_StreamKindMask	stream_kinds	Stream kind of the data samples that are of interest.

Table 15.9 DDS\_QueryConditionParams

Type	Field Name	Description
struct DDS_ReadConditionParams	as_readconditionparam	Read condition parameters
char *	query_expression	Expression for the query.
struct DDS_StringSeq	query_parameters	Parameters for the query expression.

### 15.9.7.1 How ReadConditions are Triggered

A *ReadCondition* has a **trigger\_value** that determines whether the attached *WaitSet* is BLOCKED or UNBLOCKED. Unlike the *StatusCondition*, the **trigger\_value** of the *ReadCondition* is tied to the presence of at least one DDS sample with a sample-state, view-state, and instance-state that matches those set in the *ReadCondition*. Furthermore, for the *QueryCondition* to have a **trigger\_value**==TRUE, the data associated with the DDS sample must be such that the **query\_expression** evaluates to TRUE.

The **trigger\_value** of a *ReadCondition* depends on the presence of DDS samples on the associated *DataReader*. This implies that a single 'take' operation can potentially change the **trigger\_value** of

several *ReadConditions* or *QueryConditions*. For example, if all DDS samples are taken, any *ReadConditions* and *QueryConditions* associated with the *DataReader* that had **trigger\_value**==TRUE before will see the **trigger\_value** change to FALSE. Note that this does not guarantee that *WaitSet* objects that were separately attached to those conditions will not be awakened. Once we have **trigger\_value**==TRUE on a condition, it may wake up the attached *WaitSet*, the condition transitioning to **trigger\_value**==FALSE does not necessarily 'unwake' the *WaitSet*, since 'unwakening' may not be possible. The consequence is that an application blocked on a *WaitSet* may return from **wait()** with a list of conditions, some of which are no longer "active." This is unavoidable if multiple threads are concurrently waiting on separate *WaitSet* objects and taking data associated with the same *DataReader*.

Consider the following example: A *ReadCondition* that has a `sample_state_mask = {NOT_READ}` will have a **trigger\_value** of TRUE whenever a new DDS sample arrives and will transition to FALSE as soon as all the newly arrived DDS samples are either read (so their status changes to READ) or taken (so they are no longer managed by Connex). However, if the same *ReadCondition* had a **sample\_state\_mask = {READ, NOT\_READ}**, then the **trigger\_value** would only become FALSE once all the newly arrived DDS samples are *taken* (it is not sufficient to just *read* them, since that would only change the SampleState to READ), which overlaps the mask on the *ReadCondition*.

### 15.9.7.2 QueryConditions

A *QueryCondition* is a special *ReadCondition* that allows your application to also specify a filter on the locally available data.

The query expression is similar to a SQL WHERE clause and can be parameterized by arguments that are dynamically changeable by the **set\_query\_parameters()** operation.

*QueryConditions* are triggered in the same manner as *ReadConditions*, with the additional requirement that the DDS sample must also satisfy the conditions of the content filter associated with the *QueryCondition*.

**Table 15.10 QueryCondition Operations**

Operation	Description
<code>get_query_expression</code>	Returns the query expression specified when the <i>QueryCondition</i> was created.
<code>get_query_parameters</code>	Returns the query parameters associated with the <i>QueryCondition</i> . That is, the parameters specified on the last successful call to <b>set_query_parameters()</b> , or if <b>set_query_parameters()</b> was never called, the arguments specified when the <i>QueryCondition</i> was created.
<code>set_query_parameters</code>	Changes the query parameters associated with the <i>QueryCondition</i> .

## 15.9.8 StatusConditions

*StatusConditions* are created automatically by *Connex*, one for each *Entity*. *Connex* will trigger the *StatusCondition* when there is a change to any of that *Entity*'s enabled statuses.

By default, when *Connex* creates a *StatusCondition*, all status bits are turned on, which means it will check for all statuses to determine when to trigger the *StatusCondition*. If you only want *Connex* to check for specific statuses, you can use the *StatusCondition*'s `set_enabled_statuses()` operation and set just the desired status bits.

The `trigger_value` of the *StatusCondition* depends on the communication status of the *Entity* (e.g., arrival of data, loss of information, etc.), 'filtered' by the set of enabled statuses on the *StatusCondition*.

The set of enabled statuses and its relation to *Listeners* and *WaitSets* is detailed in [15.9.8.1 How StatusConditions are Triggered](#) below.

[Table 15.11 StatusCondition Operations](#) lists the operations available on *StatusConditions*.

**Table 15.11 StatusCondition Operations**

Operation	Description
<code>set_enabled_statuses</code>	Defines the list of communication statuses that are taken into account to determine the <code>trigger_value</code> of the <i>StatusCondition</i> . This operation may change the <code>trigger_value</code> of the <i>StatusCondition</i> . <i>WaitSets</i> behavior depend on the changes of the <code>trigger_value</code> of their attached conditions. Therefore, any <i>WaitSet</i> to which the <i>StatusCondition</i> is attached is potentially affected by this operation. If this function is not invoked, the default list of enabled statuses includes all the statuses.
<code>get_enabled_statuses</code>	Retrieves the list of communication statuses that are taken into account to determine the <code>trigger_value</code> of the <i>StatusCondition</i> . This operation returns the statuses that were explicitly set on the last call to <code>set_enabled_statuses()</code> or, if <code>set_enabled_statuses()</code> was never called, the default list
<code>get_entity</code>	Returns the <i>Entity</i> associated with the <i>StatusCondition</i> . Note that there is exactly one <i>Entity</i> associated with each <i>StatusCondition</i> .

Unlike other types of *Conditions*, *StatusConditions* are created by *Connex*, not by your application. To access an *Entity*'s *StatusCondition*, use the *Entity*'s `get_statuscondition()` operation. For example:

```
Condition* my_status_condition = entity->get_statuscondition();
```

In the Modern C++ API, use the *StatusCondition* constructor to obtain a reference to the *Entity*'s condition. For example:

```
dds::core::cond::StatusCondition my_status_condition(entity)
```

After a *StatusCondition* is triggered, call the *Entity*'s `get_status_changes()` operation to see which status(es) changed.

Note: Not all statuses will activate the *StatusCondition*. Refer to the API Reference HTML documentation of the individual statuses for that information.

### 15.9.8.1 How StatusConditions are Triggered

The `trigger_value` of a *StatusCondition* is the boolean OR of the `ChangedStatusFlag` of all the communication statuses to which it is sensitive. That is, `trigger_value` is `FALSE` only if *all* the values of

the **ChangedStatusFlags** are **FALSE**.

The sensitivity of the *StatusCondition* to a particular communication status is controlled by the list of **enabled\_statuses** set on the *Condition* by means of the **set\_enabled\_statuses()** operation.

Once a *StatusCondition*'s **trigger\_value** becomes true, it remains true until the status that changed is reset. To reset a status, call the related **get\_\*\_status()** operation. Or, in the case of the data available status, call **read()**, **take()**, or one of their variants.

Therefore, if you are using a *StatusCondition* on a *WaitSet* to be notified of events, your thread will wake up when one of the statuses associated with the *StatusCondition* becomes true. If you do not reset the status, the *StatusCondition*'s **trigger\_value** remains true and your *WaitSet* will not block again—it will immediately wake up when you call **wait()**.

### 15.9.9 Using Both Listeners and WaitSets

You can use *Listeners* and *WaitSets* in the same application. For example, you may want to use *WaitSets* and *Conditions* to access the data, and *Listeners* to be warned asynchronously of erroneous communication statuses.

We recommend that you choose one or the other mechanism for each particular communication status (not both). However, if both are enabled, the *Listener* mechanism is used first, then the *WaitSet* objects are signaled.

## 15.10 Getting, Setting, and Comparing QoS Policies

Each type of *Entity* has an associated set of QoS Policies (see [Chapter 42 All QoS Policies on page 683](#)). QoS Policies allow you to configure and set properties for the Entity.

While most QoS Policies are defined by the DDS specification, some are offered by *Connex* as extensions to control parameters specific to the implementation.

There are two ways to specify a QoS policy:

- Programmatically, as described in [Chapter 49 Configuring QoS Programmatically on page 900](#).
- From XML resources (files, strings)—with this approach, you can change the QoS without recompiling the application. The QoS settings are automatically loaded by the *DomainParticipantFactory* when the first *DomainParticipant* is created. See [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

# Chapter 16 Working with DDS Domains

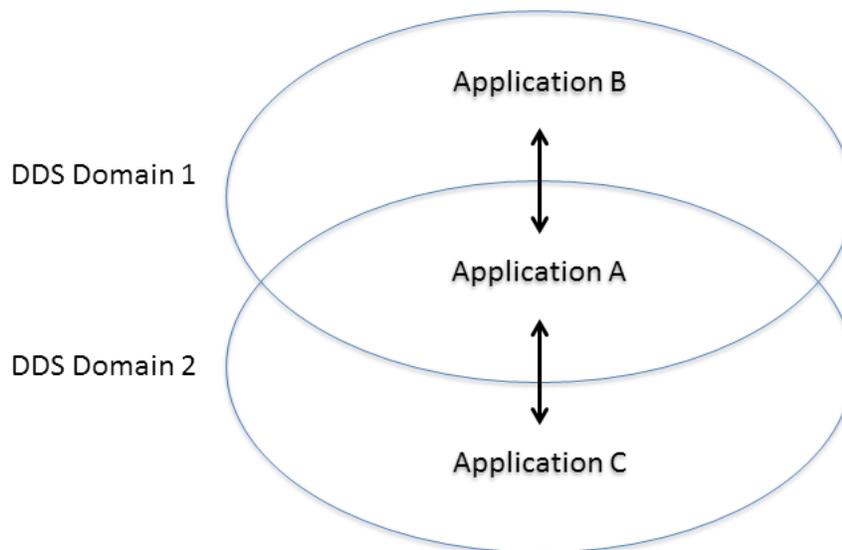

This section discusses how to use *DomainParticipants*. It describes the types of operations that are available for them and their QoS Policies. If you haven't already, read the overview information in [Chapter 12 DDS Domains and DomainParticipants on page 28](#).

The goal of this section is to help you become familiar with the objects you need for setting up your *Connex* application. For specific details on any mentioned operations, see the API Reference HTML documentation.

## 16.1 Fundamentals of DDS Domains and DomainParticipants

*DomainParticipants* are the focal point for creating, destroying, and managing other *Connex* objects. A *DDS domain* is a logical network of applications: only applications that belong to the same DDS domain may communicate using *Connex*. A DDS domain is identified by a unique integer value known as a domain ID. An application participates in a DDS domain by creating a *DomainParticipant* for that domain ID.

Figure 16.1: Relationship between Applications and DDS Domains

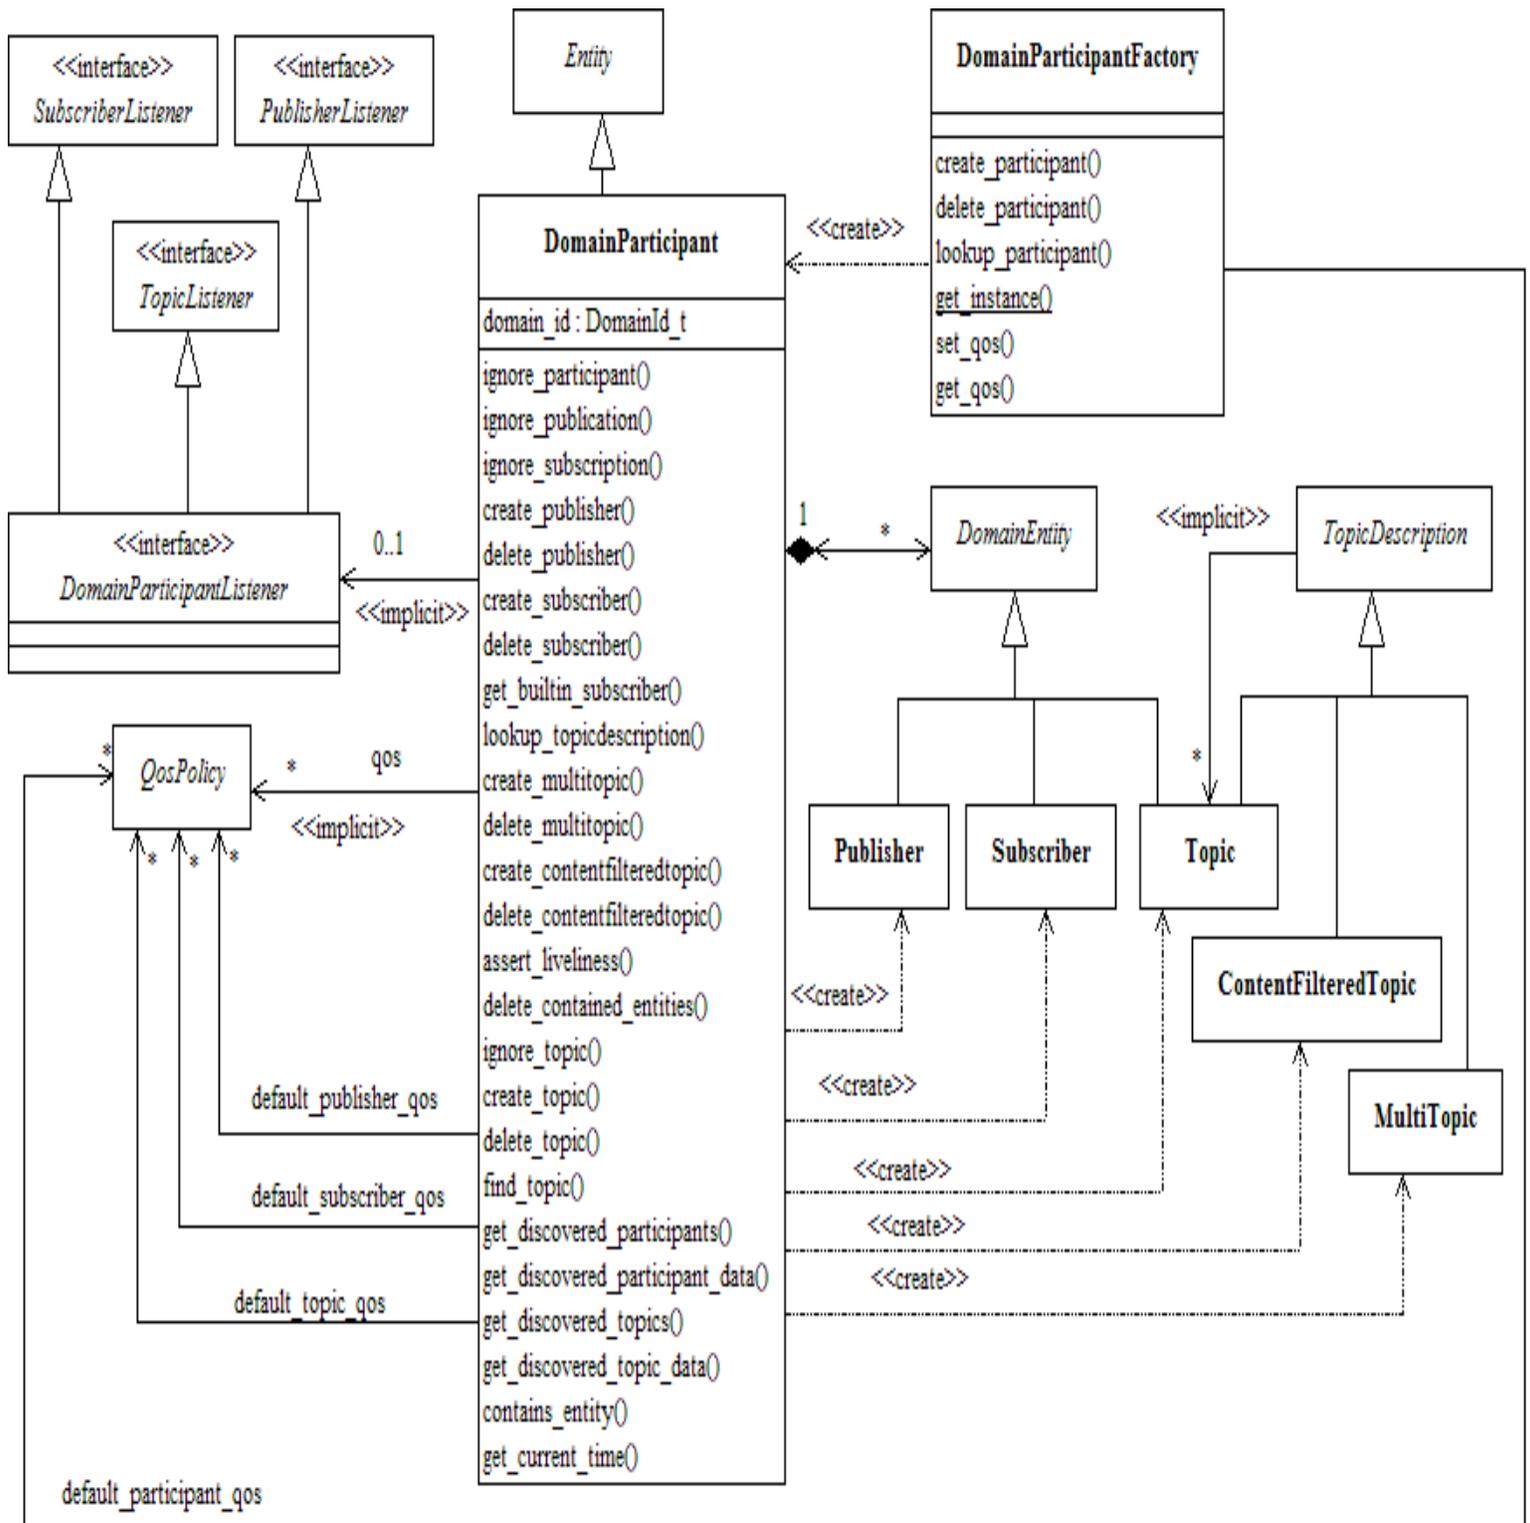

*Applications can belong to multiple DDS domains—A belongs to DDS domains 1 and 2. Applications in the same DDS domain can communicate with each other, such as A and B, or A and C. Applications in different DDS domains, such as B and C, are not even aware of each other and will not exchange messages.*

As seen in [Figure 16.1: Relationship between Applications and DDS Domains](#) above, a single application can participate in multiple DDS domains by creating multiple *DomainParticipants* with different domain IDs. *DomainParticipants* in the same DDS domain form a logical network; they are isolated from *DomainParticipants* of other DDS domains, even those running on the same set of physical computers sharing the same physical network. *DomainParticipants* in different DDS domains will never exchange messages with each other. Thus, a DDS domain establishes a “virtual network” linking all *DomainParticipants* that share the same domain ID.

An application that wants to participate in a certain DDS domain will need to create a *DomainParticipant*. As seen in [Figure 16.2: DDS Domain Module on the next page](#), a *DomainParticipant* object is a container for all other *Entities* that belong to the same DDS domain. It acts as factory for the *Publisher*, *Subscriber*, and *Topic* entities. (As seen in [Part 5: Sending Data with Connex \(on page 370\)](#) and [Overview of Receiving Data \(Chapter 38 on page 594\)](#), in turn, *Publishers* are factories for *DataWriters* and *Subscribers* are factories for *DataReaders*.) *DomainParticipants* cannot contain other *DomainParticipants*.

Like all *Entities*, *DomainParticipants* have *QosPolicies* and *Listeners*. The *DomainParticipant* entity also allows you to set ‘default’ values for the *QosPolicies* for all the entities created from it or from the entities that it creates (*Publishers*, *Subscribers*, *Topics*, *DataWriters*, and *DataReaders*).

Figure 16.2: DDS Domain Module

*Note: MultiTopics are not supported.*

## 16.2 DomainParticipantFactory

- C, Traditional C++, Java and C# APIs:

The main purpose of a *DomainParticipantFactory* is to create and destroy *DomainParticipants*.

In C++ terms, this is a singleton class; that is, you will only have a single *DomainParticipantFactory* in an application—no matter how many *DomainParticipants* the application may create. [Figure 16.3: Instantiating a DomainParticipantFactory below](#) shows how to instantiate a *DomainParticipantFactory*. Notice that there are no parameters to specify. Alternatively, in C++, the predefined macro, **DDSTheParticipantFactory**, can also be used to retrieve the singleton factory. (In C, the macro is **DDS\_TheParticipantFactory**. In Java, use the static class method **DomainParticipantFactory.TheParticipantFactory**. In C#, use **DomainParticipantFactory.Instance**.)

Unlike the other *Entities* that you create, the *DomainParticipantFactory* does not have an associated *Listener*. However, it does have associated QoS Policies, see [16.2.1 Setting DomainParticipantFactory QoS Policies on page 77](#). You can change them using the factory's **get\_qos()** and **set\_qos()** operations. The *DomainParticipantFactory* also stores the default QoS settings that can be used when a *DomainParticipant* is created. These default settings can be changed as well, see [16.3.7.5 Getting and Setting Default QoS for Child Entities on page 101](#).

**Figure 16.3: Instantiating a DomainParticipantFactory**

```
DDSDomainParticipantFactory* factory = NULL;
factory = DDSDomainParticipantFactory::get_instance();
if (factory == NULL) {
    // ... error
}
```

- Modern C++ API:

In the Modern C++ API, there isn't an explicit *DomainParticipantFactory*. *DomainParticipants* are created using their constructors and are automatically destroyed as a reference type (See [15.1 Creating and Deleting DDS Entities on page 33](#)).

The operations to set and get the default *DomainParticipantQos* are static functions in *DomainParticipant*: **DomainParticipant::default\_participant\_qos()**. The operations to look up participants are freestanding functions in the **dds::domain** and **rti::domain** namespaces: **dds::domain::find()**, **rti::domain::find\_participant\_by\_name()**, and **rti::domain::find\_participants()**. The class *QosProvider* is responsible for managing QoS profiles (see [50.5 How to Load XML-Specified QoS Settings on page 939](#)).

There is a `DomainParticipantFactoryQos`, but it only contains the `ENTITY_FACTORY` to indicate if a *DomainParticipant* should be enabled in its constructor or by calling `enable()`, and `SYSTEM_RESOURCE_LIMITS`. The `DomainParticipantFactoryQos` getter and setter are static functions in `DomainParticipant`: **`DomainParticipant::participant_factory_qos()`**.

Another static function in `DomainParticipant` allows finalizing the implicit `DomainParticipantFactory` singleton: **`DomainParticipant::finalize_participant_factory()`**.

Once you have a *DomainParticipantFactory*, you can use it to perform the operations listed in [Table 16.1 DomainParticipantFactory Operations](#). The most important one is `create_participant()`, described in [16.3.1 Creating a DomainParticipant on page 87](#). For more details on all operations, see the API Reference HTML documentation as well as the section of the manual listed in the Reference column.

**Table 16.1 DomainParticipantFactory Operations**

Working with ...	Operation	Description	Reference	
Domain-Participants	<code>create_participant</code>	Creates a <i>DomainParticipant</i> .	<a href="#">16.3.1 Creating a DomainParticipant on page 87</a>	
	<code>create_participant_with_profile</code>	Creates a <i>DomainParticipant</i> based on a QoS profile.		
	<code>delete_participant</code>	Deletes a <i>DomainParticipant</i> .	<a href="#">16.3.2 Deleting DomainParticipants on page 89</a>	
	<code>get_default_participant_qos</code>	Gets the default QoS for <i>DomainParticipants</i> .	<a href="#">16.2.2 Getting and Setting Default QoS for DomainParticipants on page 79</a>	
	<code>get_participants</code>	Returns a sequence of pointers to all the <i>DomainParticipants</i> within the <code>DomainParticipantFactory</code> .	<a href="#">16.2.4 Looking Up DomainParticipants on page 80</a>	
	<code>lookup_participant</code>	Finds a specific <i>DomainParticipant</i> , based on a domain ID.		
	<code>lookup_participant_by_name</code>	Finds a specific <i>DomainParticipant</i> , based on a domain name.		
		<code>set_default_participant_qos</code>	Sets the default QoS for <i>DomainParticipants</i> .	<a href="#">16.2.2 Getting and Setting Default QoS for DomainParticipants on page 79</a>
		<code>set_default_participant_qos_with_profile</code>	Sets the default QoS for <i>DomainParticipants</i> based on a QoS profile.	
The Factory's Instance	<code>get_instance</code>	Gets the singleton instance of this class.	<a href="#">16.2.3 Freeing Resources Used by the DomainParticipantFactory on page 79</a>	
	<code>finalize_instance</code>	Destroys the singleton instance of this class.		

Table 16.1 DomainParticipantFactory Operations

Working with ...	Operation	Description	Reference
The Factory's Own QoS	get_qos	Gets/sets the DomainParticipantFactory's QoS.	<a href="#">Chapter 49 Configuring QoS Programmatically on page 900</a>
	set_qos		
	equals	Compares two DomainParticipantFactory's QoS structures for equality.	
Threads	set_thread_factory	Specifies a ThreadFactory implementation that DomainParticipants will use to create and delete all threads.	<a href="#">Chapter 70 User-Managed Threads on page 1194</a>
	unregister_thread	Frees all resources related to a thread.  This function is intended to be used at the end of any user-created threads that invoke <i>Connex</i> APIs (not all users will have this situation). The best approach is to call it immediately before exiting such a thread, after all <i>Connex</i> APIs have been called.	
Profiles & Libraries	get_default_library	Gets the default library for a DomainParticipantFactory.	<a href="#">16.2.1.1 Getting and Setting the DomainParticipantFactory's Default QoS Profile and Library on the next page</a>
	get_default_profile	Gets the default QoS profile for a DomainParticipantFactory.	
	get_default_profile_library	Gets the library that contains the default QoS profile for a <i>DomainParticipantFactory</i> .	
	get_<entity>_qos_from_profile	Gets the <entity> QoS values associated with a specified QoS profile. <entity> may be <i>topic</i> , <i>datareader</i> , <i>datawriter</i> , <i>subscriber</i> , <i>publisher</i> , or <i>participant</i> .	<a href="#">16.2.5 Getting QoS Values from a QoS Profile on page 80</a>
	get_<entity>_qos_from_profile_w_topic_name	Like get_<entity>_qos_from_profile(), but this operation allows you to specify a topic name associated with the entity. The topic filter expressions in the profile will be evaluated on the topic name.  <entity> may be <i>topic</i> , <i>datareader</i> , or <i>datawriter</i> .	
	get_qos_profiles	Gets the names of all XML QoS profiles associated with a specified XML QoS profile library.	<a href="#">50.4 Tags for Configuring QoS with XML on page 931</a>
	get_qos_profile_libraries	Gets the names of all XML QoS profile libraries associated with the DomainParticipantFactory.	<a href="#">50.10.1 Retrieving a List of Available Libraries on page 952</a>
	load_profiles	Explicitly loads or reloads the QoS profiles.	<a href="#">50.5.1 Loading, Reloading and Unloading Profiles on page 941</a>
	reload_profiles		
	set_default_profile	Sets the default QoS profile for a DomainParticipantFactory.	<a href="#">16.2.1.1 Getting and Setting the DomainParticipantFactory's Default QoS Profile and Library on the next page</a>
	set_default_library	Sets the default library for a DomainParticipantFactory.	
unload_profiles	Frees the resources associated with loading QoS profiles.	<a href="#">50.5.1 Loading, Reloading and Unloading Profiles on page 941</a>	

## 16.2.1 Setting DomainParticipantFactory QoS Policies

The DDS\_DomainParticipantFactoryQoS structure has the following format:

```

struct DDS_DomainParticipantFactoryQos {
    DDS_EntityFactoryQosPolicy    entity_factory;
    DDS_SystemResourceLimitsQosPolicy  resource_limits;
    DDS_ProfileQosPolicy          profile;
    DDS_LoggingQosPolicy          logging;
};

```

For information on *why* you would want to change a particular QoS Policy, see the section referenced in [Table 16.2 DomainParticipantFactory QoS](#).

**Table 16.2 DomainParticipantFactory QoS**

QoS Policy	Description
EntityFactory	Controls whether or not child entities are created in the enabled state. See <a href="#">46.2 ENTITYFACTORY QoS Policy on page 743</a> .
Logging	Configures the properties associated with <i>Connex</i> logging. See <a href="#">43.1 LOGGING QoS Policy (DDS Extension) on page 690</a> .
Profile	Configures the way that XML documents containing QoS profiles are loaded by RTI. See <a href="#">43.2 PROFILE QoS Policy (DDS Extension) on page 691</a> .
SystemResourceLimits	Configures <i>DomainParticipant</i> -independent resources used by <i>Connex</i> . Mainly used to change the maximum number of <i>DomainParticipants</i> that can be created within a single process (address space). See <a href="#">43.3 SYSTEM_RESOURCE_LIMITS QoS Policy (DDS Extension) on page 693</a> .

### 16.2.1.1 Getting and Setting the DomainParticipantFactory's Default QoS Profile and Library

You can retrieve the default QoS profile for the DomainParticipantFactory with the `get_default_profile()` operation. You can also get the default library for the DomainParticipantFactory, as well as the library that contains the DomainParticipantFactory's default profile (these are not necessarily the same library); these operations are called `get_default_library()` and `get_default_library_profile()`, respectively. These operations are for informational purposes only (that is, you do not need to use them as a precursor to setting a library or profile.) For more information, see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

```

virtual const char *  get_default_library ()
const char *  get_default_profile ()
const char *  get_default_profile_library ()

```

There are also operations for setting the DomainParticipantFactory's default library and profile:

```

DDS_ReturnCode_t set_default_library (const char *  library_name)
DDS_ReturnCode_t set_default_profile (const char *  library_name,
                                     const char *  profile_name)

```

`set_default_profile()` specifies the profile that will be used as the default the next time a default DomainParticipantFactory profile is needed during a call to a DomainParticipantFactory operation.

When calling a DomainParticipantFactory operation that requires a `profile_name` parameter, you can use NULL to refer to the default profile. (This same information applies to setting a default library.)

`set_default_profile()` does not set the default QoS for the *DomainParticipant* that can be created by the *DomainParticipantFactory*. To set the default QoS using a profile, use the *DomainParticipantFactory*'s `set_default_participant_qos_with_profile()` operation (see [16.2.2 Getting and Setting Default QoS for DomainParticipants below](#)).

## 16.2.2 Getting and Setting Default QoS for DomainParticipants

To *get* the default QoS that will be used for creating *DomainParticipants* if `create_participant()` is called with `DDS_PARTICIPANT_QOS_DEFAULT` as the `qos` parameter, use this *DomainParticipantFactory* operation:

```
DDS_ReturnCode_t get_default_participant_qos (DDS_DomainParticipantQos & qos)
```

This operation gets the QoS settings that were specified on the last successful call to `set_default_participant_qos()` or `set_default_participant_qos_with_profile()`, or if the call was never made, the default values listed in `DDS_DomainParticipantQos`.

To *set* the default QoS that will be used for new *DomainParticipants*, use the following operations. Then these default QoS will be used if `create_participant()` is called with `DDS_PARTICIPANT_QOS_DEFAULT` as the 'qos' parameter.

```
DDS_ReturnCode_t set_default_participant_qos (
    const DDS_DomainParticipantQos &qos)
```

or

```
DDS_ReturnCode_t set_default_participant_qos_with_profile (
    const char *library_name, const char *profile_name)
```

### Notes:

- These operations may potentially allocate memory, depending on the sequences contained in some QoS policies.
- It is not safe to set the default *DomainParticipant* QoS values while another thread may be simultaneously calling `get_default_participant_qos()`, `set_default_participant_qos()`, or `create_participant()` with `DDS_PARTICIPANT_QOS_DEFAULT` as the `qos` parameter. It is also not safe to get the default *DomainParticipant* QoS values while another thread may be simultaneously calling `set_default_participant_qos()`.

## 16.2.3 Freeing Resources Used by the DomainParticipantFactory

The `finalize_instance()` operation explicitly reclaims resources used by the participant factory singleton (including resources use for QoS profiles).

On many operating systems, these resources are automatically reclaimed by the OS when the program terminates. However, some memory-check tools will flag those resources as unreclaimed. This method provides a way to clean up all the memory used by the participant factory.

Before calling **finalize\_instance()** on a *DomainParticipantFactory*, all of the participants created by the factory must have been deleted. For a *DomainParticipant* to be successfully deleted, all *Entities* created by the participant or by the *Entities* that the participant created must have been deleted. In essence, the *DomainParticipantFactory* cannot be deleted until all other *Entities* have been deleted in an application.

Except for Linux systems: **get\_instance()** and **finalize\_instance()** are UNSAFE on the FIRST call. It is not safe for two threads to simultaneously make the first call to get or finalize the factory instance. Subsequent calls are thread safe.

## 16.2.4 Looking Up DomainParticipants

The *DomainParticipantFactory* has these useful operations for retrieving its *DomainParticipants*:

- **get\_participants()** returns a sequence of pointers to all the *DomainParticipants* within the *DomainParticipantFactory*.

```
DDS_ReturnCode_t
    get_participants (DDSDomainParticipantSeq & participants)
```

- **lookup\_participant()** locates an existing *DomainParticipant* based on its domain ID.

```
DDSDomainParticipant *
    lookup_participant (DDS_DomainId_t domainId)
```

- **lookup\_participant\_by\_name ()** locates an existing *DomainParticipant* based on its name.

```
DDSDomainParticipant *
    lookup_participant_by_name(const char * participant_name)
```

Note: in the Modern C++ API these operations are freestanding functions **rti::domain::find\_participants()**, **dds::domain::find()**, and **rti::domain::find\_participant\_by\_name()**, respectively.

## 16.2.5 Getting QoS Values from a QoS Profile

A QoS Profile may include configuration settings for all types of *Entities*. If you just want the settings for a specific type of *Entity*, call **get\_<entity>\_qos\_from\_profile()** (where *<entity>* may be **participant**, **publisher**, **subscriber**, **datawriter**, **datareader**, or **topic**). This is useful if you want to get the QoS values from the profile in a structure, make some changes, and then use that structure to create an entity.

```
DDS_ReturnCode_t get_<entity>_qos_from_profile (
    DDS_<Entity>Qos &qos,
    const char *library_name,
    const char *profile_name)
```

For an example, see [Figure 30.5: Getting QoS Values from a Profile, Changing QoS Values, Creating a Publisher with Modified QoS Values on page 381](#).

The `get_<entity>_qos_from_profile()` operations do not take into account the `topic_filter` attributes that may be set for *DataWriter*, *DataReader*, or *Topic* QoSs in profiles (see [50.2.4 Topic Filters on page 926](#)). If there is a topic name associated with an entity, you can call `get_<entity>_qos_from_profile_w_topic_name()` (where `<entity>` can be `datawriter`, `datareader`, or `topic`) and the topic filter expressions in the profile will be evaluated on the topic name.

```
DDS_ReturnCode_t get_<entity>_qos_from_profile_w_topic_name(
    DDS_<entity>Qos &qos,
    const char *library_name,
    const char *profile_name,
    const char *topic_name)
```

`get_<entity>_qos_from_profile()` and `get_<entity>_qos_from_profile_w_topic_name()` may allocate memory, depending on the sequences contained in some QoS policies.

Note: in the Modern C++ API, the class `QosProvider` provides the functionality described in this section. Please see the API Reference HTML documentation: [Modules](#), [RTI Connext API Reference](#), [Configuring QoS Profiles with XML](#), [QosProvider](#).

## 16.3 DomainParticipants

A *DomainParticipant* is a container for *Entity* objects that all belong to the same DDS domain. Each *DomainParticipant* has its own set of internal threads and internal data structures that maintain information about the *Entities* created by itself and other *DomainParticipants* in the same DDS domain. A *DomainParticipant* is used to create and destroy *Publishers*, *Subscribers* and *Topics*.

Once you have a *DomainParticipant*, you can use it to perform the operations listed in [Table 16.3 DomainParticipant Operations](#). For more details on all operations, see the API Reference HTML documentation. Some of the first operations you'll be interested in are `create_topic()`, `create_subscriber()`, and `create_publisher()`.

**Note:** Some operations cannot be used within a listener callback, see [15.8.8.1 Restricted Operations in Listener Callbacks on page 57](#).

Table 16.3 DomainParticipant Operations

Working with ...	Operation	Description	Reference
Builtin Subscriber	get_builtin_subscriber	Returns the builtin Subscriber.	<a href="#">28.2 Built-in DataReaders on page 360</a>
Domain-Participants	add_peer	Adds an entry to the peer list.	<a href="#">44.2.3 Adding and Removing Peers List Entries on page 700</a>
	enable	Enables the <i>DomainParticipant</i> .	<a href="#">15.2 Enabling DDS Entities on page 35</a>
	equals	Compares two <i>DomainParticipant</i> 's QoS structures for equality.	<a href="#">16.3.7.2 Comparing QoS Values on page 99</a>
	get_discovered_participant_data	Provides the ParticipantBuiltinTopicData for a discovered <i>DomainParticipant</i> .	<a href="#">16.3.12 Learning about Discovered DomainParticipants on page 104</a>
	get_discovered_participants	Provides a list of <i>DomainParticipants</i> that have been discovered.	
	get_domain_id	Gets the domain ID of the <i>DomainParticipant</i> .	<a href="#">16.3.4 Choosing a Domain ID and Creating Multiple DDS Domains on page 90</a>
	get_listener	Gets the currently installed <i>DomainParticipantListener</i> .	<a href="#">16.3.6 Setting Up DomainParticipantListeners on page 94</a>
	get_qos	Gets the <i>DomainParticipant</i> QoS.	<a href="#">16.3.7 Setting DomainParticipant QoS Policies on page 96</a>
	ignore_participant	Rejects the connection to a remote <i>DomainParticipant</i> .	<a href="#">Chapter 27 Restricting Communication—Ignoring Entities on page 352</a>
	remove_peer	Removes an entry from the peer list.	<a href="#">44.2.3 Adding and Removing Peers List Entries on page 700</a>
	set_listener	Replaces the <i>DomainParticipantListener</i> .	<a href="#">16.3.6 Setting Up DomainParticipantListeners on page 94</a>
	set_qos	Sets the <i>DomainParticipant</i> QoS.	<a href="#">16.3.7 Setting DomainParticipant QoS Policies on page 96</a>
	set_qos_with_profile	Sets the <i>DomainParticipant</i> QoS based on a QoS profile.	

Table 16.3 DomainParticipant Operations

Working with ...	Operation	Description	Reference
Content-Filtered-Topics	create_contentfilteredtopic	Creates a ContentFilteredTopic that can be used to process content-based subscriptions.	<a href="#">35.2 Creating ContentFilteredTopics on page 548</a>
	create_contentfilteredtopic_with_filter		
	delete_contentfilteredtopic	Deletes a ContentFilteredTopic.	<a href="#">35.3 Deleting ContentFilteredTopics on page 552</a>
	register_contentfilter	Registers a new content filter.	<a href="#">35.9.2 Registering a Custom Filter on page 568</a>
	unregister_contentfilter	Unregisters a new content filter.	<a href="#">35.9.3 Unregistering a Custom Filter on page 570</a>
	lookup_contentfilter	Gets a previously registered content filter.	<a href="#">35.9.4 Retrieving a ContentFilter on page 571</a>
DataReaders	create_datareader	Creates a <i>DataReader</i> with a given <i>DataReaderListener</i> , and an implicit <i>Subscriber</i> .	<a href="#">40.1 Creating DataReaders on page 620</a>
	create_datareader_with_profile	Creates a <i>DataReader</i> based on a QoS profile, with a given <i>DataReaderListener</i> , and an implicit <i>Subscriber</i> .	
	delete_datareader	Deletes a <i>DataReader</i> that belongs to the 'implicit <i>Subscriber</i> .'	<a href="#">40.3 Deleting DataReaders on page 622</a>
	get_default_datareader_qos	Copies the default <i>DataReaderQoS</i> values into the provided structure.	<a href="#">16.3.7.5 Getting and Setting Default QoS for Child Entities on page 101</a>
	ignore_subscription	Rejects the connection to a <i>DataReader</i>	
	set_default_datareader_qos	Sets the default <i>DataReaderQoS</i> values.	
	set_default_datareader_qos_with_profile	Sets the default <i>DataReaderQoS</i> using values from a QoS profile.	

Table 16.3 DomainParticipant Operations

Working with ...	Operation	Description	Reference
DataWriters	create_datawriter	Creates a <i>DataWriter</i> with a given <i>DataWriterListener</i> , and an implicit <i>Publisher</i> .	<a href="#">30.2 Creating Publishers on page 377</a>
	create_datawriter_with_profile	Creates a <i>DataWriter</i> based on a QoS profile, with a given <i>DataWriterListener</i> , and an implicit <i>Publisher</i> .	
	delete_datawriter	Deletes a <i>DataWriter</i> that belongs to the 'implicit <i>Publisher</i> .'	<a href="#">30.3 Deleting Publishers on page 378</a>
	ignore_publication	Rejects the connection to a <i>DataWriter</i> .	<a href="#">Chapter 27 Restricting Communication—Ignoring Entities on page 352</a>
	get_default_datawriter_qos	Copies the default <i>DataWriterQos</i> values into the provided <i>DataWriterQos</i> structure.	<a href="#">16.3.7.5 Getting and Setting Default QoS for Child Entities on page 101</a>
	set_default_datawriter_qos	Sets the default <i>DataWriterQoS</i> values.	
	set_default_datawriter_qos_with_profile	Sets the default <i>DataWriterQos</i> using values from a profile.	
Publishers	create_publisher	Creates a <i>Publisher</i> and a <i>PublisherListener</i> .	<a href="#">30.2 Creating Publishers on page 377</a>
	create_publisher_with_profile	Creates a <i>Publisher</i> based on a QoS profile, and a <i>PublisherListener</i> .	
	delete_publisher	Deletes a <i>Publisher</i> .	<a href="#">30.3 Deleting Publishers on page 378</a>
	get_default_publisher_qos	Copies the default <i>PublisherQos</i> values into the provided <i>PublisherQos</i> structure.	<a href="#">16.3.7.5 Getting and Setting Default QoS for Child Entities on page 101</a>
	get_implicit_publisher	Gets the <i>Publisher</i> that is implicitly created by the <i>DomainParticipant</i> .	<a href="#">16.3.10 Getting the Implicit Publisher or Subscriber on page 103</a>
	get_publishers	Provides a list of all <i>Publishers</i> owned by the <i>DomainParticipant</i> .	<a href="#">16.3.16.3 Getting All Publishers and Subscribers on page 107</a>
	set_default_publisher_qos	Sets the default <i>PublisherQos</i> values.	<a href="#">16.3.7.5 Getting and Setting Default QoS for Child Entities on page 101</a>
	set_default_publisher_qos_with_profile	Sets the default <i>PublisherQos</i> using values from a QoS profile.	

Table 16.3 DomainParticipant Operations

Working with ...	Operation	Description	Reference
Subscribers	create_subscriber	Creates a <i>Subscriber</i> and a <i>SubscriberListener</i> .	<a href="#">39.2 Creating Subscribers on page 601</a>
	create_subscriber_with_profile	Creates a <i>Subscriber</i> based on a QoS profile, and a <i>SubscriberListener</i> .	
	delete_subscriber	Deletes a <i>Subscriber</i> .	<a href="#">39.3 Deleting Subscribers on page 602</a>
	get_default_subscriber_qos	Copies the default <i>SubscriberQos</i> values into the provided <i>SubscriberQos</i> structure.	<a href="#">16.3.7.5 Getting and Setting Default QoS for Child Entities on page 101</a>
	get_implicit_subscriber	Gets the <i>Subscriber</i> that is implicitly created by the <i>DomainParticipant</i> .	<a href="#">16.3.10 Getting the Implicit Publisher or Subscriber on page 103</a>
	get_subscribers	Provides a list of all <i>Subscribers</i> owned by the <i>DomainParticipant</i> .	<a href="#">16.3.16.3 Getting All Publishers and Subscribers on page 107</a>
	set_default_subscriber_qos	Sets the default <i>SubscriberQos</i> values.	<a href="#">16.3.7.5 Getting and Setting Default QoS for Child Entities on page 101</a>
	set_default_subscriber_qos_with_profile	Sets the default <i>SubscriberQos</i> values using values from a QoS profile.	
Durable Subscriptions	delete_durable_subscription	Deletes an existing Durable Subscription. The quorum of the existing DDS samples will be considered satisfied.	<a href="#">74.9 Configuring Durable Subscriptions in Persistence Service on page 1226</a>
	register_durable_subscription	<p>Creates a Durable Subscription that will receive all DDS samples published on a <i>Topic</i>, including those published while a <i>DataReader</i> is inactive or before it may be created.</p> <p><i>RTI Persistence Service</i> will ensure that all the DDS samples on that <i>Topic</i> are retained until they are acknowledged by at least <i>N DataReaders</i> belonging to the Durable Subscription, where <i>N</i> is the quorum count.</p> <p>If the same Durable Subscription is created on a different <i>Topic</i>, <i>RTI Persistence Service</i> will implicitly delete the previous Durable Subscription and create a new one on the new <i>Topic</i>.</p>	

Table 16.3 DomainParticipant Operations

Working with ...	Operation	Description	Reference
Topics	create_topic	Creates a <i>Topic</i> and a TopicListener.	<a href="#">18.1.1 Creating Topics on page 248</a>
	create_topic_with_profile	Creates a Topic based on a QoS profile, and a TopicListener.	
	delete_topic	Deletes a <i>Topic</i> .	
	get_default_topic_qos	Copies the default TopicQos values into the provided TopicQos structure.	<a href="#">16.3.7.5 Getting and Setting Default QoS for Child Entities on page 101</a>
	get_discovered_topic_data	Retrieves the BuiltinTopicData for a discovered <i>Topic</i> .	<a href="#">16.3.13 Learning about Discovered Topics on page 104</a>
	get_discovered_topics	Returns a list of all (non-ignored) discovered <i>Topics</i> .	
	ignore_topic	Rejects a remote topic.	<a href="#">Chapter 27 Restricting Communication—Ignoring Entities on page 352</a>
	lookup_topicdescription	Gets an existing locally-created TopicDescription (Topic).	<a href="#">16.3.8 Looking up Topic Descriptions on page 102</a>
	set_default_topic_qos	Sets the default TopicQos values.	<a href="#">16.3.7.5 Getting and Setting Default QoS for Child Entities on page 101</a>
	set_default_topic_qos_with_profile	Sets the default TopicQos values using values from a profile.	
	find_topic	Finds an existing Topic, based on its name.	<a href="#">16.3.9 Finding a Topic on page 102</a>
	Flow-Controllers	create_flowcontroller	Creates a custom FlowController object.
delete_flowcontroller		Deletes a custom FlowController object.	
get_default_flowcontroller_property		Gets the default properties used when a new FlowController is created.	<a href="#">34.4.7 Getting/Setting Default FlowController Properties on page 544</a>
set_default_flowcontroller_property		Sets the default properties used when a new FlowController is created.	
lookup_flowcontroller		Finds a FlowController, based on its name.	<a href="#">34.4.10 Other FlowController Operations on page 545</a>
Libraries and Profiles	get_default_library	Gets the default library.	<a href="#">16.3.7.4 Getting and Setting DomainParticipant's Default QoS Profile and Library on page 100</a>
	get_default_profile	Gets the default profile.	
	get_default_profile_library	Gets the library that contains the default profile.	
	set_default_profile	Sets the default QoS profile.	
	set_default_library	Sets the default library.	

Table 16.3 DomainParticipant Operations

Working with ...	Operation	Description	Reference
MultiTopics	create_multitopic	Creates a <i>MultiTopic</i> that can be used to subscribe to multiple topics and combine/filter the received data into a resulting type.	Currently not supported.
	delete_multitopic	Deletes a <i>MultiTopic</i> .	
Other	assert_liveliness	Manually asserts the liveliness of this <i>DomainParticipant</i> .	<a href="#">16.3.10 Getting the Implicit Publisher or Subscriber on page 103</a>
	delete_contained_entities	Recursively deletes all the entities that were created using the "create" operations on the <i>DomainParticipant</i> and its children.	<a href="#">16.3.3 Deleting Contained Entities on page 90</a>
	contains_entity	Confirms if an entity belongs to the <i>DomainParticipant</i> or not.	<a href="#">16.3.16.1 Verifying Entity Containment on page 106</a>
	get_current_time	Gets the current time used by <i>Connex</i> .	<a href="#">16.3.16.2 Getting the Current Time on page 107</a>
	get_status_changes	Gets a list of statuses that have changed since the last time the application read the status or the <i>Listeners</i> were called.	<a href="#">15.4 Getting Status and Status Changes on page 38</a>

## 16.3.1 Creating a DomainParticipant

Typically, you will only need to create one *DomainParticipant* per DDS domain per application. (Although unusual, you can create multiple *DomainParticipants* for the same DDS domain in an application.)

To create a *DomainParticipant*, use the *DomainParticipantFactory*'s `create_participant()` or `create_participant_with_profile()` operation:

A QoS profile is way to use QoS settings from an XML file or string. With this approach, you can change QoS settings without recompiling the application. For details, see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

Note: In the Modern C++ API, you will use the *DomainParticipant* constructors.

```

DDSDomainParticipant * create_participant (
    DDS_DomainId_t domainId,
    const DDS_DomainParticipantQos &qos,
    DDSDomainParticipantListener *listener,
    DDS_StatusMask mask)
DDSDomainParticipant * create_participant_with_profile (
    DDS_DomainId_t domainId,
    const char * library_name,
    const char *profile_name,
    DDSDomainParticipantListener *listener,
    DDS_StatusMask mask)

```

Where:

---

<b>domainId</b>	The domain ID uniquely identifies the DDS domain that the <i>DomainParticipant</i> is in. It controls with which other <i>DomainParticipants</i> it will communicate. See <a href="#">16.3.4 Choosing a Domain ID and Creating Multiple DDS Domains on page 90</a> for more information on domain IDs.
<b>qos</b>	<p>If you want the default QoS settings (described in the API Reference HTML documentation), use <code>DDS_PARTICIPANT_QOS_DEFAULT</code> for this parameter (see <a href="#">Figure 16.4: Creating a DomainParticipant with Default QoS Policies on the next page</a>). If you want to customize any of the QoS policies, supply a <i>DomainParticipantQos</i> structure that is described in <a href="#">16.3.7 Setting DomainParticipant QoS Policies on page 96</a>.</p> <p><b>Note:</b> If you use <code>DDS_PARTICIPANT_QOS_DEFAULT</code>, it is not safe to create the <i>DomainParticipant</i> while another thread may simultaneously be calling the <i>DomainParticipantFactory</i>'s <code>set_default_participant_qos()</code> operation.</p>
<b>listener</b>	Listeners are callback routines. <i>Connex</i> uses them to notify your application of specific events (status changes) that may occur. The listener parameter may be set to <code>NULL</code> if you do not want to install a <i>Listener</i> . The <i>DomainParticipant's Listener</i> is a catchall for all of the events of all of its <i>Entities</i> . If an event is not handled by an <i>Entity's Listener</i> , then the <i>DomainParticipantListener</i> may be called in response to the event. For more information, see <a href="#">16.3.6 Setting Up DomainParticipantListeners on page 94</a> .
<b>mask</b>	This bit mask indicates which status changes will cause the <i>Listener</i> to be invoked. The bits set in the mask must have corresponding callbacks implemented in the <i>Listener</i> . If you use <code>NULL</code> for the <i>Listener</i> , use <code>DDS_STATUS_MASK_NONE</code> for this parameter. If the <i>Listener</i> implements all callbacks, use <code>DDS_STATUS_MASK_ALL</code> . For information on statuses, see <a href="#">15.8 Listeners on page 46</a> .
<b>library_name</b>	A QoS Library is a named set of QoS profiles. See <a href="#">50.2 QoS Profiles on page 906</a> .
<b>profile_name</b>	<p>A QoS profile groups a set of related QoS, usually one per entity. See <a href="#">50.2 QoS Profiles on page 906</a>.</p> <p>After you create a <i>DomainParticipant</i>, the next step is to register the data types that will be used by the application, see <a href="#">17.6 Using RTI Code Generator (rtiddsgen) on page 234</a>. Then you will need to create the <i>Topics</i> that the application will publish and/or subscribe, see <a href="#">18.1.1 Creating Topics on page 248</a>. Finally, you will use the <i>DomainParticipant</i> to create <i>Publishers</i> and/or <i>Subscribers</i>, see <a href="#">30.2 Creating Publishers on page 377</a> and <a href="#">39.2 Creating Subscribers on page 601</a>.</p> <p><b>Note:</b> It is not safe to create one <i>DomainParticipant</i> while another thread may simultaneously be looking up (<a href="#">16.2.4 Looking Up DomainParticipants on page 80</a>) or deleting (<a href="#">16.3.2 Deleting DomainParticipants on the next page</a>) the same <i>DomainParticipant</i>.</p> <p>For more examples, see <a href="#">16.3.7.1 Configuring QoS Settings when DomainParticipant is Created on page 97</a>.</p>

Figure 16.4: Creating a DomainParticipant with Default QoS Policies

```

DDS_DomainId_t domain_id = 10;
// MyDomainParticipantListener is user defined and
// extends DDSDomainParticipantListener
MyDomainParticipantListener* participant_listener =
    new MyDomainParticipantListener(); // or = NULL
// Create the participant
DDSDomainParticipant* participant = factory->create_participant(
    domain_id, DDS_PARTICIPANT_QOS_DEFAULT,
    participant_listener, DDS_STATUS_MASK_ALL);
if (participant == NULL) {
    // ... error
};

```

## 16.3.2 Deleting DomainParticipants

If the application is no longer interested in communicating in a certain DDS domain, the *DomainParticipant* can be deleted. A *DomainParticipant* can be deleted only after all the *Entities* that were created by the *DomainParticipant* have been deleted (see [16.3.3 Deleting Contained Entities on the next page](#)).

To delete a *DomainParticipant*:

You must first delete all *Entities* (*Publishers*, *Subscribers*, *ContentFilteredTopics*, and *Topics*) that were created with the *DomainParticipant*. Use the *DomainParticipant*'s `delete_<entity>()` operations to delete them one at a time, or use the `delete_contained_entities()` operation ([16.3.3 Deleting Contained Entities on the next page](#)) to delete them all at the same time.

```

DDS_ReturnCode_t delete_publisher (DDSPublisher *p)
DDS_ReturnCode_t delete_subscriber (DDSSubscriber *s)
DDS_ReturnCode_t delete_contentfilteredtopic
    (DDSContentFilteredTopic *a_contentfilteredtopic)
DDS_ReturnCode_t delete_topic (DDSTopic *topic)

```

Delete the *DomainParticipant* by using the *DomainParticipantFactory*'s `delete_participant()` operation.

```

DDS_ReturnCode_t delete_participant
    (DDSDomainParticipant *a_participant)

```

**Note:** A *DomainParticipant* cannot be deleted within its *Listener* callback, see [15.8.8.1 Restricted Operations in Listener Callbacks on page 57](#).

After a *DomainParticipant* has been deleted, all of the participant's internal *Connex*t threads and allocated memory will have been deleted. You should delete the *DomainParticipantListener* only after the *DomainParticipant* itself has been deleted.

Note: In the Modern C++ API, *Entities* are automatically destroyed.

### 16.3.3 Deleting Contained Entities

The *DomainParticipant*'s `delete_contained_entities()` operation deletes all the *Publishers* (including an implicitly created one, if it exists), *Subscribers* (including an implicitly created one, if it exists), *ContentFilteredTopics*, and *Topics* that have been created by the *DomainParticipant*.

```
DDS_ReturnCode_t delete_contained_entities( )
```

Prior to deleting each contained entity, this operation recursively calls the corresponding `delete_contained_entities()` operation on each contained entity (if applicable). This pattern is applied recursively. Therefore, `delete_contained_entities()` on the *DomainParticipant* will end up deleting all the entities recursively contained in the *DomainParticipant*, that is also the *DataWriter*, *DataReader*, as well as the *QueryCondition* and *ReadCondition* objects belonging to the contained *DataReader*.

If `delete_contained_entities()` returns successfully, the application may delete the **DomainParticipant** knowing that it has no contained entities (see [16.3.2 Deleting DomainParticipants on the previous page](#)).

### 16.3.4 Choosing a Domain ID and Creating Multiple DDS Domains

A domain ID identifies the DDS domain in which the *DomainParticipant* is communicating. *DomainParticipants* with the same domain ID are on the same communication “channel” (or “databus”). *DomainParticipants* with different domain IDs are completely isolated from each other.

The domain ID is a purely arbitrary value; you can use any integer 0 or higher, provided it does not violate the guidelines for the `DDS_RtpsWellKnownPorts_t` structure ([44.9.2 Ports Used for Discovery on page 732](#)). Domain IDs are typically between 0 and 232. Please see the API Reference HTML documentation for the `DDS_RtpsWellKnownPorts_t` structure and in particular, `DDS_INTEROPERABLE RTPS_WELL_KNOWN_PORTS`.

**Note:** On Windows, you should avoid using ports 49152 through 65535 for inbound traffic. *Connect*'s ephemeral ports (see [Chapter 23 Ports Used for Discovery on page 319](#)) may be within that range (see [https://msdn.microsoft.com/en-us/library/windows/desktop/ms737550\(v=vs.85\).aspx](https://msdn.microsoft.com/en-us/library/windows/desktop/ms737550(v=vs.85).aspx)). With the default `RtpsWellKnownPorts` settings, port 49152 corresponds to domain ID 167, so using domain IDs 168 through 232 on Windows introduces the risk of a port collision and failure to create the *DomainParticipant* when using multicast discovery. You may see this error:

```
RTIOsapiSocket_bindWithIP:OS bind() failure, error 0X271D: An attempt was made to access a socket in a way forbidden by its access permissions.
```

Most distributed systems can use a single DDS domain for all of its applications. Thus a single domain ID is sufficient. Some systems may need to logically partition nodes to prevent them from communicating with each other directly, and thus will need to use multiple DDS domains. However, even in systems that only use a single DDS domain, during the testing and development phases, one may want to assign different users/testers different domain IDs for running their applications so that their tests do not interfere with each other.

To run multiple applications on the same node with the same domain ID, *Connex* uses a participant ID to distinguish between the different *DomainParticipants* in the different applications. The participant ID is simply an integer value that must be unique across all *DomainParticipants* created on the same node that use the same domain ID. The `participant_id` is part of the [44.9 WIRE\\_PROTOCOL QosPolicy \(DDS Extension\) on page 730](#).

Although usually those *DomainParticipants* have been created in different applications, the same application can also create multiple *DomainParticipants* with the same domain ID. For optimal results, the `participant_id` should be assigned sequentially to the different *DomainParticipants*, starting from the default value of 0.

Once you have a *DomainParticipant*, you can retrieve its domain ID with the `get_domain_id()` operation.

The domain ID and participant ID are mapped to port numbers that are used by transports for discovery traffic. For information on how port numbers are calculated, see [Chapter 23 Ports Used for Discovery on page 319](#). How *DomainParticipants* discover each other is discussed in [Discovery Overview \(Chapter 22 on page 309\)](#).

## 16.3.5 Isolating DomainParticipants and Endpoints from Each Other

There are several ways to prevent *Entities* from communicating with each other:

- *Domain IDs* physically isolate entire applications (and their *DomainParticipants*) from each other. See [16.3.4 Choosing a Domain ID and Creating Multiple DDS Domains on the previous page](#).
- *Domain tags* enable you to logically subdivide domains, isolating them from each other. Domain tags cannot be changed after creating the *DomainParticipant*. See [16.3.5.1 Choosing a Domain Tag on the next page](#).
- *DomainParticipant partitions* enable you to have different visibility planes for a given pair of domain ID and domain tag. Only *DomainParticipants* with at least one matching partition can communicate with each other. Membership in a partition can be dynamically changed. See [46.5 PARTITION QosPolicy on page 751](#).
- *DomainParticipant-ignoring API*. The API `DomainParticipant::ignore_participant` can be used to ignore a remote *DomainParticipant* at the application level. See [27.1 Ignoring Specific Remote DomainParticipants on page 353](#).
- *Endpoint (DataWriter/DataReader) partitions* enable you to have different visibility planes at the *Publisher/Subscriber* level. A *DataWriter* will not see a *DataReader* unless their corresponding *Publisher* or *Subscriber* has at least one matching partition. Membership in a partition can be dynamically changed. See [46.5 PARTITION QosPolicy on page 751](#).

- *Endpoint-ignoring APIs.* The APIs **DomainParticipant::ignore\_publication** and **DomainParticipant::ignore\_subscription** can be used to ignore remote endpoints at the application level. See [27.2 Ignoring Publications and Subscriptions on page 354](#).

[Table 16.4 Isolating, Partitioning, and Filtering Information](#) provides a comprehensive comparison of these different methods and specifically addresses what, if any, discovery traffic is reduced or eliminated.

**Table 16.4 Isolating, Partitioning, and Filtering Information**

Concept	Description	Isolates Participant Discovery Traffic	Isolates Endpoint Discovery Traffic	Isolates Endpoint Communication	Changeable
Domain ID	Hard databus isolation	Yes	Yes	Yes	No
Domain tag	Logical databus isolation	No	Yes	Yes	No
<i>DomainParticipant</i> partition	Participant visibility planes	No	Yes	Yes	Yes
Ignore-participant API	Application-level isolation for DomainParticipants	No	Yes	Yes	No (the action cannot be undone)
Endpoint (writer-/reader) partition	Endpoint visibility planes	No	No	Yes	Yes
Ignore-endpoint API	Application-level isolation for endpoints	No	No	Yes	No (the action cannot be undone)

**Legend:**

- **Isolates Participant Discovery Traffic.** Participants do not exchange RTPS participant DATA submessages or authenticate with each other (see [22.1 Simple Participant Discovery on page 310](#)).
- **Isolates Endpoint Discovery.** Participants do not exchange RTPS publication DATAs and subscription DATAs submessages (see [22.3 Simple Endpoint Discovery on page 317](#)).
- **Isolates Endpoint Communication.** There is no RTPS traffic sent between endpoints.

In addition to isolating entities, you can configure a *DataReader* to receive only a subset of the data published by a matching *DataWriter*, based on the content of the data, using *ContentFilteredTopics* (see [18.3 ContentFilteredTopics on page 256](#)) or based on the frequency of the data using time-based filters (see [48.4 TIME\\_BASED\\_FILTER QosPolicy on page 888](#)).

### 16.3.5.1 Choosing a Domain Tag

The domain tag is an intuitive way of subdividing domains. It consists of a string value (with a maximum of 255 characters). It allows *DomainParticipants* to drop participant discovery messages not

belonging to the same domain tag they are using. The domain tag is immutable, and cannot be changed after creating the *DomainParticipant*.

Unlike domain IDs, domain tags are not mapped to port numbers that are used by transports for discovery traffic. Consequently, a *DomainParticipant* may receive participant discovery traffic belonging to a different domain tag; however, this traffic will be dropped upon reception. Another consequence of domain tags having no impact on port mapping is that multiple *DomainParticipants* running on the same machine with the same domain ID, but with different domain tags, will end up using different participant IDs to avoid port collision.

As an example, a system with six *DomainParticipants* could be configured as follows:

- Participant A: domain ID = 24, domain tag = "ENG. DEPT"
- Participant B: domain ID = 24, domain tag = "ENG. DEPT"
- Participant C: domain ID = 24, domain tag = "SALES DEPT"
- Participant D: domain ID = 24, domain tag = "SALES DEPT"
- Participant E: domain ID = 42, domain tag = "ENG. DEPT"
- Participant F: domain ID = 42, domain tag = "ENG. DEPT"

In this system, Participants A, B, C, and D are all on the same domain ID, so all of them will receive the discovery traffic belonging to domain 24; however, only *DomainParticipant* pairs A-B and C-D will be able to discover each other, since they have a matching domain tag. (Any discovery message not matching the expected domain tag will be dropped.) Participants E and F are in a different domain (42), so they are completely isolated from the rest, not even receiving the discovery traffic from the rest of the *DomainParticipants*. For more information, see [22.1 Simple Participant Discovery on page 310](#).

By default, a *DomainParticipant* is in an empty ("", zero-length string) domain tag. To associate a domain tag with a *DomainParticipant*, use the following *DomainParticipant* PropertyQos property:

**dds.domain\_participant.domain\_tag:** A string (with a maximum of 255 characters) defining the domain tag the *DomainParticipant* will propagate through Participant Discovery. Participants will drop any Participant discovery message that contains a domain tag that does not match the local domain tag. This parameter is only propagated if it is set to a value different than the default. Default: "" (empty, zero-length string).

**Note:** While domain ID is fully supported across the whole *Connex*t ecosystem, domain tag support is currently limited to the Core Libraries and infrastructure Services (by setting the aforementioned *DomainParticipant* PropertyQos property). Domain tags are not well supported in *Connex*t tools (such as *Admin Console*). *Connex*t tools do not provide a tool-specific mechanism to configure domain tags. Consequently, if you configure an application to use domain tags, that application will not be able to communicate with *Connex*t tools, unless you edit the tool's QoS configuration (if it has one—for instance, see *Admin Console's* Preferences dialog) to use domain tags.

See also: [16.3.5 Isolating DomainParticipants and Endpoints from Each Other on page 91](#).

### 16.3.5.2 Creating DomainParticipant Partitions

Use the [46.5 PARTITION QosPolicy on page 751](#) to create partitions at the *DomainParticipant*, *Publisher*, or *Subscriber* level.

## 16.3.6 Setting Up DomainParticipantListeners

*DomainParticipants* may optionally have *Listeners*. *Listeners* are essentially callback routines and are how *Connex*t will notify your application of specific events (changes in status) for entities *Topics*, *Publishers*, *Subscribers*, *DataWriters*, and *DataReaders*. Each *Entity* may have a *Listener* installed and enabled to process the events for itself and all of the sub-*Entities* created from it. If an *Entity* does not have a *Listener* installed or is not enabled to listen for a particular event, then *Connex*t will propagate the event to the *Entity*'s parent. If the parent *Entity* does not process the event, *Connex*t will continue to propagate the event up the object hierarchy until either a *Listener* is invoked or the event is dropped.

The *DomainParticipantListener* is the last chance that an event can be processed for the *Entities* descended from a *DomainParticipant*. The *DomainParticipantListener* is used only if an event is not handled by any of the *Entities* contained by the participant.

A *Listener* is typically set up when the *DomainParticipant* is created (see [16.3.1 Creating a DomainParticipant on page 87](#)). You can also set one up after creation time by using the `set_listener()` operation, as illustrated in [Figure 16.5: Setting up DomainParticipantListener below](#). The `get_listener()` operation can be used to retrieve the current *DomainParticipantListener*.

**Figure 16.5: Setting up DomainParticipantListener**

```
// MyDomainParticipantListener only handles PUBLICATION_MATCHED and
// SUBSCRIPTION_MATCHED status for DomainParticipant Entities
class MyDomainParticipantListener :
    public DDSDomainParticipantListener {
public:
    virtual void on_publication_matched(DDSDataWriter *writer,
        const DDS_PublicationMatchedStatus &status);
    virtual void on_subscription_matched(DDSDataReader *reader,
        const DDS_SubscriptionMatchedStatus &status);
};

void MyDomainParticipantListener::on_publication_matched(
    DDSDataWriter *writer,
    const DDS_PublicationMatchedStatus &status)
{
    const char *name = writer->get_topic()->get_name();
    printf("Number of matching DataReaders for Topic %s is %d\n",
        name, status.current_count);
};

void MyDomainParticipantListener::on_subscription_matched(
    DDSDataReader *reader,
    const DDS_SubscriptionMatchedStatus &status)
{
    const char *name =
```

```

        reader->get_topicdescription()->get_name();
        printf("Number of matching DataWriters for Topic %s is %d\n",
            name, status.current_count);
    };

    // Set up participant listener
    MyDomainParticipantListener* participant_listener =
        new MyDomainParticipantListener();
    if (participant_listener == NULL) {
        // ... handle error
    }
    // Create the participant with a listener
    DDSDomainParticipant* participant = factory->create_participant(
        domain_id, participant_qos, participant_listener,
        DDS_PUBLICATION_MATCHED_STATUS |
        DDS_SUBSCRIPTION_MATCHED_STATUS );
    if (participant == NULL) {
        // ... handle error
    }
}

```

If a *Listener* is set for a *DomainParticipant*, the *Listener* needs to exist as long as the *DomainParticipant* exists. It is unsafe to destroy the *Listener* while it is attached to a participant. However, you may remove the *DomainParticipantListener* from a *DomainParticipant* by calling **set\_listener()** with a NULL value. Once the *Listener* has been removed from the participant, you may safely destroy it (see [15.8.1 Types of Listeners on page 47](#)).

#### Notes:

- Due to a thread-safety issue, the destruction of a *DomainParticipantListener* from an enabled *DomainParticipant* should be avoided—even if the *DomainParticipantListener* has been removed from the *DomainParticipant*. (This limitation does not affect the Java API.)
- It is possible for multiple internal *Connext* threads to call the same method of a *DomainParticipantListener* simultaneously. You must write the methods of a *DomainParticipantListener* to be multithread safe and reentrant. The methods of the *Listener* of other Entities do not have this constraint and are guaranteed to have single threaded access.

- [40.4 Setting Up DataReaderListeners on page 622](#)

## 16.3.7 Setting DomainParticipant QoS Policies

A *DomainParticipant*'s QoS Policies are used to configure discovery, database sizing, threads, information sent to other *DomainParticipants*, and the behavior of the *DomainParticipant* when acting as a factory for other *Entities*.

Note: `set_qos()` cannot always be used in a listener callback; see [15.8.8.1 Restricted Operations in Listener Callbacks on page 57](#).

The `DDS_DomainParticipantQos` structure has the following format:

```
struct DDS_DomainParticipantQos {
    DDS_UserDataQosPolicy      user_data;
    DDS_EntityFactoryQosPolicy entity_factory;
    DDS_WireProtocolQosPolicy  wire_protocol;
    DDS_TransportBuiltinQosPolicy transport_builtin;
    DDS_TransportUnicastQosPolicy default_unicast;
    DDS_DiscoveryQosPolicy     discovery;
    DDS_DomainParticipantResourceLimitsQosPolicy resource_limits;
    DDS_EventQosPolicy         event;
    DDS_ReceiverPoolQosPolicy  receiver_pool;
    DDS_DatabaseQosPolicy     database;
    DDS_DiscoveryConfigQosPolicy discovery_config;
    DDS_PropertyQosPolicy     property;
    DDS_EntityNameQosPolicy   participant_name;
    DDS_TransportMulticastMappingQosPolicy multicast_mapping;
    DDS_ServiceQosPolicy      service;
    DDS_TypeSupportQosPolicy  type_support;
};
```

[Table 16.5 DomainParticipant QoS Policies](#) summarizes the meaning of each policy (listed alphabetically). For information on *why* you would want to change a particular QoS Policy, see the section referenced in the table.

**Table 16.5 DomainParticipant QoS Policies**

QoS Policy	Description
Database	Various settings and resource limits used by <i>Connex</i> t to control its internal database. See <a href="#">44.1 DATABASE QoS Policy (DDS Extension) on page 696</a> .
Discovery	Configures the mechanism used by <i>Connex</i> t to automatically discover and connect with new remote applications. See <a href="#">44.2 DISCOVERY QoS Policy (DDS Extension) on page 699</a> .
DiscoveryConfig	Controls the amount of delay in discovering entities in the system and the amount of discovery traffic in the network. See <a href="#">44.3 DISCOVERY_CONFIG QoS Policy (DDS Extension) on page 703</a> .
DomainParticipantResourceLimits	Various settings that configure how <i>DomainParticipants</i> allocate and use physical memory for internal resources, including the maximum sizes of various properties. See <a href="#">44.4 DOMAIN_PARTICIPANT_RESOURCE_LIMITS QoS Policy (DDS Extension) on page 714</a> .
EntityFactory	Controls whether or not child entities are created in the enabled state. See <a href="#">46.2 ENTITYFACTORY QoS Policy on page 743</a> .

Table 16.5 DomainParticipant QoS Policies

QoS Policy	Description
EntityName	Assigns a name to a <i>DomainParticipant</i> . See <a href="#">47.11 ENTITY_NAME QoS Policy (DDS Extension) on page 817</a> .
Event	Configures the <i>DomainParticipant</i> 's internal thread that handles timed events. See <a href="#">44.5 EVENT QoS Policy (DDS Extension) on page 721</a> .
Partition	Adds string identifiers that are used for partitioning <i>DomainParticipants</i> that have the same domain ID and domain tag. See <a href="#">46.5 PARTITION QoS Policy on page 751</a> .
Property	Stores name/value(string) pairs that can be used to configure certain parameters of <i>Connex</i> t that are not exposed through formal QoS policies. It can also be used to store and propagate application-specific name/value pairs, which can be retrieved by user code during discovery. See <a href="#">47.19 PROPERTY QoS Policy (DDS Extension) on page 837</a> .
ReceiverPool	Configures threads used by <i>Connex</i> t to receive and process data from transports (for example, UDP sockets). See <a href="#">44.6 RECEIVER_POOL QoS Policy (DDS Extension) on page 723</a> .
Service	Intended for use by RTI infrastructure services. User applications should not modify its value. See <a href="#">47.23 SERVICE QoS Policy (DDS Extension) on page 853</a> .
TransportBuiltin	Specifies which built-in transport plugins are used. See <a href="#">44.7 TRANSPORT_BUILTIN QoS Policy (DDS Extension) on page 725</a> .
TransportMulticastMapping	Specifies the automatic mapping between a list of topic expressions and multicast address that can be used by a <i>DataReader</i> to receive data for a specific topic. See <a href="#">44.8 TRANSPORT_MULTICAST_MAPPING QoS Policy (DDS Extension) on page 727</a> .
TransportUnicast	Specifies a subset of transports and port number that can be used by an Entity to receive data. See <a href="#">47.28 TRANSPORT_UNICAST QoS Policy (DDS Extension) on page 859</a> .
TypeSupport	Used to attach application-specific value(s) to a <i>DataWriter</i> or <i>DataReader</i> . These values are passed to the serialization or deserialization routine of the associated data type. See <a href="#">47.29 TYPESUPPORT QoS Policy (DDS Extension) on page 863</a> .
UserData	Along with Topic Data QoS Policy and Group Data QoS Policy, used to attach a buffer of bytes to <i>Connex</i> t's discovery meta-data. See <a href="#">47.30 USER_DATA QoS Policy on page 864</a> .
WireProtocol	Specifies IDs used by the RTPS wire protocol to create globally unique identifiers. See <a href="#">44.9 WIRE_PROTOCOL QoS Policy (DDS Extension) on page 730</a> .

### 16.3.7.1 Configuring QoS Settings when DomainParticipant is Created

As described in [16.3.1 Creating a DomainParticipant on page 87](#), there are different ways to create a *DomainParticipant*, depending on how you want to specify its QoS (with or without a QoS Profile).

- [Figure 16.4: Creating a DomainParticipant with Default QoS Policies on page 89](#) has an example of how to create a *DomainParticipant* with default QoS Policies by using the special constant, `DDS_PARTICIPANT_QOS_DEFAULT`, which indicates that the default QoS values for a *DomainParticipant* should be used. The default *DomainParticipant* QoS values are configured in the *DomainParticipantFactory*; you can change them with `set_default_participant_qos()` or `set_default_participant_qos_with_profile()` (see [16.2.2 Getting and Setting Default QoS for DomainParticipants on page 79](#)). Then any *DomainParticipants* created with the *DomainParticipantFactory* will use the new default values. As described in [Chapter 49 Configuring QoS](#)

Programmatically on page 900, this is a general pattern that applies to the construction of all Entities.

- To create a DomainParticipant with non-default QoS without using a QoS Profile, see the example code in [Figure 16.6: Creating DomainParticipant with Modified QoS Policies \(not from profile\) below](#). It uses the *DomainParticipantFactory*'s `get_default_participant_qos()` method to initialize a `DDS_ParticipantQos` structure. Then, the policies are modified from their default values before the structure is used in the `create_participant()` method.
- You can also create a DomainParticipant and specify its QoS settings via a QoS Profile. To do so, you will call `create_participant_with_profile()`, as seen in [Figure 16.7: Creating DomainParticipant with QoS Profile below](#).
- If you want to use a QoS profile, but then make some changes to the QoS before creating the DomainParticipant, call `get_participant_qos_from_profile()` and `create_participant()` as seen in [Figure 16.8: Getting QoS from Profile, Creating DomainParticipant with Modified QoS Values on the next page](#).

For more information, see [16.3.1 Creating a DomainParticipant on page 87](#) and [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

#### Notes:

- The examples in this section use the Traditional C++ API; for examples in the Modern C++ API, see the sections "Participant Use Cases," "QoS Use Cases," and "QoS Provider Use Cases" in the API Reference HTML documentation, under "Programming How-To's."
- In C, you must initialize the QoS structures before they are used, see [42.2 Special QoS Policy Handling Considerations for C on page 688](#).

**Figure 16.6: Creating DomainParticipant with Modified QoS Policies (not from profile)**

```
DDS_DomainId_t domain_id = 10;
DDS_DomainParticipantQos participant_qos;
// initialize participant_qos with default values
factory->get_default_participant_qos(participant_qos);
// make QoS changes here
participant_qos.wire_protocol.participant_id = 2;
// Create the participant with modified qos
DDSDomainParticipant* participant = factory->create_participant(
    domain_id, participant_qos, NULL, DDS_STATUS_MASK_NONE);
if (participant == NULL) {
    // ... error
}
```

**Figure 16.7: Creating DomainParticipant with QoS Profile**

```
DDS_DomainId_t domain_id = 10;
// MyDomainParticipantListener is user defined and
// extends DDSDomainParticipantListener
MyDomainParticipantListener* participant_listener
```

```

    = new MyDomainParticipantListener(); // or = NULL
// Create the participant
DDSDomainParticipant* participant =
    factory->create_participant_with_profile(domain_id,
        "MyDomainLibrary", "MyDomainProfile",
        participant_listener, DDS_STATUS_MASK_ALL);
if (participant == NULL) {
    // ... error
};

```

**Figure 16.8: Getting QoS from Profile, Creating DomainParticipant with Modified QoS Values**

```

DDS_DomainParticipantQos participant_qos;
// Get DomainParticipant QoS from profile
retcode = factory->get_participant_qos_from_profile( participant_qos,
    "DomainParticipantProfileLibrary", "DomainParticipantProfile");
if (retcode != DDS_RETCODE_OK) {
    // handle error
}
// Makes QoS changes here
participant_qos.entity_factory.autoenable_created_entities = DDS_BOOLEAN_FALSE;
// create participant with modified QoS
DDSDomainParticipant* participant = factory->create_participant(domain_id,
    participant_qos, NULL, DDS_STATUS_MASK_NONE);
if (participant == NULL) {
    // handle error
}

```

### 16.3.7.2 Comparing QoS Values

The **equals()** operation compares two *DomainParticipant*'s `DDS_DomainParticipantQoS` structures for equality. It takes two parameters for the two *DomainParticipant*'s QoS structures to be compared, then returns `TRUE` if they are equal (all values are the same) or `FALSE` if they are not equal.

### 16.3.7.3 Changing QoS Settings After DomainParticipant Has Been Created

There are two ways to change an existing *DomainParticipant*'s QoS after it has been created—again depending on whether or not you are using a QoS Profile.

- To change QoS programmatically (that is, without using a QoS Profile), use **get\_qos()** and **set\_qos()**. See the example code in [Figure 16.9: Changing QoS of Existing Participant \(without QoS Profile\) on the next page](#). It retrieves the current values by calling the *DomainParticipant*'s **get\_qos()** operation. Then it modifies the value and calls **set\_qos()** to apply the new value. Note, however, that some QoS Policies cannot be changed after the *DomainParticipant* has been enabled—this restriction is noted in the descriptions of the individual QoS Policies.
- You can also change a *DomainParticipant*'s (and all other Entities') QoS by using a QoS Profile and calling **set\_qos\_with\_profile()**. For an example, see [Figure 16.10: Changing QoS of Existing Participant with QoS Profile on the next page](#). For more information, see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

**Note:**

- In C, you must initialize the QoS structures before they are used, see [42.2 Special QoS Policy Handling Considerations for C](#) on page 688.

**Figure 16.9: Changing QoS of Existing Participant (without QoS Profile)**

```
DDS_DomainParticipantQos participant_qos;
// Get current QoS
//participant points to an existing DDSDomainParticipant
if (participant->get_qos(participant_qos) != DDS_RETCODE_OK) {
    // handle error
}
// Make QoS changes
participant_qos.entity_factory.autoenable_created_entities =
    DDS_BOOLEAN_FALSE;
// Set the new QoS
if (participant->set_qos(participant_qos) != DDS_RETCODE_OK ) {
    // handle error
}
```

**Figure 16.10: Changing QoS of Existing Participant with QoS Profile**

```
DDS_DomainParticipantQos participant_qos;
// Get current QoS
//participant points to an existing DDSDomainParticipant
if (participant->get_qos(participant_qos) != DDS_RETCODE_OK) {
    // handle error
}
// Make QoS changes
participant_qos.entity_factory.autoenable_created_entities =
    DDS_BOOLEAN_FALSE;
// Set the new QoS
if (participant->set_qos(participant_qos) != DDS_RETCODE_OK ) {
    // handle error
}
```

**16.3.7.4 Getting and Setting DomainParticipant's Default QoS Profile and Library**

You can get the default QoS profile for the *DomainParticipant* with the **get\_default\_profile()** operation. You can also get the default library for the *DomainParticipant*, as well as the library that contains the *DomainParticipant's* default profile (these are not necessarily the same library); these operations are called **get\_default\_library()** and **get\_default\_library\_profile()**, respectively. These operations are for informational purposes only (that is, you do not need to use them as a precursor to setting a library or profile.) For more information, see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

```
virtual const char * get_default_library ()
const char * get_default_profile ()
const char * get_default_profile_library ()
```

There are also operations for *setting* the *DomainParticipant's* default library and profile:

```
DDS_ReturnCode_t set_default_library (
    const char * library_name)
DDS_ReturnCode_t set_default_profile (
    const char * library_name,
    const char * profile_name)
```

If the default profile/library is not set, the *DomainParticipant* inherits the default from the *DomainParticipantFactory*.

- **set\_default\_profile()** specifies the profile that will be used as the default the next time a default *DomainParticipant* profile is needed during a call to one of this *DomainParticipant*'s operations. When calling a *DomainParticipant* operation that requires a **profile\_name** parameter, you can use NULL to refer to the default profile. (This same information applies to setting a default library.)
- **set\_default\_profile()** does not set the default QoS for entities created by the *DomainParticipant*; for this functionality, use the *DomainParticipant*'s **set\_default\_<entity>\_qos\_with\_profile()** operation (you may pass in NULL after having called **set\_default\_profile()**, see [16.3.7.5 Getting and Setting Default QoS for Child Entities](#) below).
- **set\_default\_profile()** does not set the default QoS for newly created *DomainParticipants*; for this functionality, use the *DomainParticipantFactory*'s **set\_default\_participant\_qos\_with\_profile()**, see [16.2.2 Getting and Setting Default QoS for DomainParticipants on page 79](#)).

### 16.3.7.5 Getting and Setting Default QoS for Child Entities

The **set\_default\_<entity>\_qos()** and **set\_default\_<entity>\_qos\_with\_profile()** operations set the default QoS that will be used for newly created entities (where *<entity>* may be **publisher**, **subscriber**, **datawriter**, **datareader**, or **topic**). The new QoS settings will only be used if **DDS\_<entity>\_QOS\_DEFAULT** is specified as the **qos** parameter when **create\_<entity>()** is called. For example, for a *Publisher*, you can use either:

```
DDS_ReturnCode_t set_default_publisher_qos (
    const DDS_PublisherQos &qos)
DDS_ReturnCode_t set_default_publisher_qos_with_profile (
    const char *library_name,
    const char *profile_name)
```

The following operation gets the default QoS that will be used for creating *Publishers* if **DDS\_PUBLISHER\_QOS\_DEFAULT** is specified as the 'qos' parameter when **create\_publisher()** is called:

```
DDS_ReturnCode_t get_default_publisher_qos (
    DDS_PublisherQos & qos)
```

There are similar operations for *Subscribers*, *DataWriters*, *DataReaders* and *Topics*. These operations, **get\_default\_<entity>\_qos()**, get the QoS settings that were specified on the last successful call to **set\_default\_<entity>\_qos()** or **set\_default\_<entity>\_qos\_with\_profile()**, or if the call was never made, the default values listed in **DDS\_<entity>Qos**. They may potentially allocate memory depending on the sequences contained in some QoS policies.

**Note:** It is not safe to set default QoS values for an entity while another thread may be simultaneously getting or setting them, or using the `QOS_DEFAULT` constant to create the entity.

## 16.3.8 Looking up Topic Descriptions

The `lookup_topicdescription()` operation allows you to access a locally created `DDSTopicDescription` based on the *Topic*'s name.

```
DDSTopicDescription* lookup_topicdescription(const char *topic_name)
```

`DDSTopicDescription` is the base class for *Topics*, *MultiTopics*<sup>1</sup> and *ContentFilteredTopics*. You can narrow the `DDSTopicDescription` returned from `lookup_topicdescription()` to a *Topic* or *ContentFilteredTopic* as appropriate.

Unlike `find_topic()` (see 16.3.9 Finding a Topic below), which logically returns a new *Topic* that must be independently deleted, *this operation returns a reference to the original local object.*

If no `TopicDescription` has been created yet with the given *Topic* name, this method will return a `NULL` value.

The *DomainParticipant* does not have to be enabled when you call `lookup_topicdescription()`.

**Note:** It is not safe to create or delete a topic while another thread is calling `lookup_topicdescription()` for that same topic.

## 16.3.9 Finding a Topic

The `find_topic()` operation finds an existing (or ready to exist) *Topic*, based on its name. This call can be used to block for a specified duration to wait for the *Topic* to be created.

```
DDSTopic* DDSDomainParticipant::find_topic (const char * topic_name,
                                           const DDS_Duration_t & timeout)
```

If the requested *Topic* already exists, it is returned. Otherwise, `find_topic()` waits until either another thread creates it, or returns when the specified timeout occurs.

`find_topic()` is useful when multiple threads are concurrently creating and looking up topics. In that case, one thread can call `find_topic()` and, if another thread has not yet created the topic being looked up, it can wait for some period of time for it to do so. In almost all other cases, it is more straightforward to call `lookup_topicdescription()` (see 16.3.8 Looking up Topic Descriptions above).

The *DomainParticipant* must be enabled when you call `find_topic()`.

**Note:** Each `DDSTopic` obtained by `find_topic()` must also be deleted by calling the *DomainParticipant*'s `delete_topic()` operation (see 18.1.2 Deleting Topics on page 250).

<sup>1</sup>*Multitopics* are not supported.

## 16.3.10 Getting the Implicit Publisher or Subscriber

The `get_implicit_publisher()` operation allows you to access the *DomainParticipant's* implicit *Publisher*. If one does not already exist, this operation creates an implicit *Publisher*.

There is a similar operation for implicit *Subscribers*:

```
DDSPublisher * get_implicit_publisher ()
DDSSubscriber * get_implicit_subscriber()
```

There can only be one implicit *Publisher* and one implicit *Subscriber* per *DomainParticipant*. They are created with default QoS values (`DDS_PUBLISHER_QOS_DEFAULT`) and no Listener. For more information, see [30.1 Creating Publishers Explicitly vs. Implicitly on page 376](#). You can use an implicit *Publisher* or implicit *Subscriber* just like an explicitly created one.

An implicit *Publisher/Subscriber* is deleted automatically when `delete_contained_entities()` is called. It can also be deleted by calling `delete_publisher/subscriber()` with the implicit *Publisher/Subscriber* as a parameter.

When a *DomainParticipant* is deleted, if there are no attached *DataReaders* that belong to the implicit *Subscriber* or no attached *DataWriters* that belong to the implicit *Publisher*, any implicit *Publisher/Subscriber* will be deleted by the middleware implicitly.

**Note:** It is not safe to create an implicit *Publisher/Subscriber* while another thread may be simultaneously calling `set_default_[publisher/subscriber]_qos()`.

**How to get the implicit *Publisher/Subscriber*. (For simplicity, error handling is not shown.)**

```
using namespace DDS;
...
Publisher * publisher = NULL;
Subscriber * subscriber = NULL;
PublisherQos publisher_qos;
SubscriberQos subscriber_qos;
...
publisher = participant->get_implicit_publisher();
/* Change implicit publisher QoS */
publisher->get_qos(publisher_qos);
publisher_qos.partition.name.maximum(3);
publisher_qos.partition.name.length(3);
publisher_qos.partition.name[0] = DDS_String_dup("partition_A");
publisher_qos.partition.name[1] = DDS_String_dup("partition_B");
publisher_qos.partition.name[2] = DDS_String_dup("partition_C");
publisher->set_qos(publisher_qos);
/* Get implicit subscriber */
subscriber = participant->get_implicit_subscriber();
/* Change implicit subscriber QoS */
subscriber_qos.partition.name.maximum(3);
subscriber_qos.partition.name.length(3);
subscriber_qos.partition.name[0] = DDS_String_dup("partition_A");
subscriber_qos.partition.name[1] = DDS_String_dup("partition_B");
subscriber_qos.partition.name[2] = DDS_String_dup("partition_C");
subscriber->set_qos(subscriber_qos);
```

### 16.3.11 Asserting Liveliness

The `assert_liveliness()` operation manually asserts the liveliness of all the *DataWriters* created by this *DomainParticipant* that has [47.15 LIVELINESS QosPolicy on page 825](#) kind set to `MANUAL_BY_PARTICIPANT`. When `assert_liveliness()` is called, then for those *DataWriters* who have their `LIVELINESS` set to `MANUAL_BY_PARTICIPANT`, *Connex* will send a packet to all matched *DataReaders* that indicates that the *DataWriter* is still alive.

However, the `LIVELINESS` contract of periodically sending liveliness packets to *DataReaders* is also fulfilled when the `write()`, `assert_liveliness()`, `unregister_instance()` and `dispose()` operations on a *DataWriter* itself is called. Those calls will also cause *Connex* to send packets that indicate the liveliness of the *DataWriter*. Therefore, it is necessary for the application to call `assert_liveliness()` on the *DomainParticipant* only if those operations on a *DataWriter* are not being invoked within the period specified by the [47.15 LIVELINESS QosPolicy on page 825](#)

### 16.3.12 Learning about Discovered DomainParticipants

The `get_discovered_participants()` operation provides you with a list of *DomainParticipants* that have been discovered in the DDS domain (except any that you have said to ignore via the `ignore_participant()` operation (see [Chapter 27 Restricting Communication—Ignoring Entities on page 352](#))).

Once you have a list of discovered *DomainParticipants*, you can get more information about them by calling the `get_discovered_participant_data()` operation. This operation can only be used on *DomainParticipants* that are in the same DDS domain and have not been marked as ‘ignored.’ Otherwise, the operation will fail and return `DDS_RETCODE_PRECONDITION_NOT_MET`. The returned information is of type `DDS_ParticipantBuiltinTopicData`, described in [Table 28.1 Participant Built-in Topic’s Data Type \(DDS\\_ParticipantBuiltinTopicData\)](#).

### 16.3.13 Learning about Discovered Topics

The `get_discovered_topics()` operation provides you with a list of *Topics* that have been discovered in the DDS domain (except any that you have said to ignore via the `ignore_topic()` operation (see [Chapter 27 Restricting Communication—Ignoring Entities on page 352](#))).

Once you have a list of discovered *Topics*, you can get more information about them by calling the `get_discovered_topic_data()` operation. This operation can only be used on *Topics* that have been created by a *DomainParticipant* in the same DDS domain as the participant on which this operation is invoked and must not have been “ignored” by means of the *DomainParticipant* `ignore_topic()` operation. Otherwise, the operation will fail and return `DDS_RETCODE_PRECONDITION_NOT_MET`. The returned information is of type `DDS_TopicBuiltinTopicData`, described in [Table 28.4 Topic Built-in Topic’s Data Type \(DDS\\_TopicBuiltinTopicData\)](#).

## 16.3.14 Getting Participant Protocol Status

Statistics about corrupted RTPS messages received by the participant can be obtained from the `DomainParticipantProtocolStatus`.

**Table 16.6** `DDS_DomainParticipantProtocolStatus`

Type	Field Name	Description
DDS_LongLong	<code>corrupted_rtps_message_count</code>	The number of corrupted RTPS messages detected by the participant.
DDS_LongLong	<code>corrupted_rtps_message_count_change</code>	The incremental change in the number of corrupted messages detected since the last time the status was read.
DDS_Time_t	<code>last_corrupted_message_timestamp</code>	The timestamp of the last corrupted RTPS message detected by the participant.

You can get the `DomainParticipantProtocolStatus` by using the `get_participant_protocol_status()` operation. The `WireProtocolQosPolicy`'s `compute_crc` and `check_crc` must be enabled in the publishing and subscribing applications, respectively, when the protocol status is obtained.

```
DDS_ReturnCode_t get_participant_protocol_status(DDS_DomainParticipantProtocolStatus
&status)
```

## 16.3.15 Configuring the Clock per DomainParticipant

*Connex* uses clocks to measure time and generate timestamps.

The middleware uses two clocks: an internal clock and an external clock.

- The internal clock measures time and handles all timing in the middleware.
- The external clock is used solely to generate timestamps (such as the source timestamp and the reception timestamp), in addition to providing the time given by the *DomainParticipant*'s `get_current_time()` operation (see [16.3.16.2 Getting the Current Time on page 107](#)).

### 16.3.15.1 Available Clocks

Two clock implementations are generally available: the *real-time* clock and the *monotonic* clock.

The real-time clock provides the real time of the system. This clock may generally be monotonic, but may not be guaranteed to be so. It is adjustable and may be subject to small and large changes in time. The time obtained from this clock is generally a meaningful time, in that it is the amount of time from a known epoch. For the purposes of clock selection, this clock can be referenced by the names **"realtime"** or **"system"**—*both names map to the same real-time clock*.

The monotonic clock provides times that are monotonic from a clock that is not adjustable. This clock is not subject to changes in the system or realtime clock, which may be adjusted by the user or via time synchronization protocols. However, this clock's time generally starts from an arbitrary point in time,

such as system start-up. Note that the monotonic clock is not available for all architectures. Please see the [RTI Connexx Core Libraries Platform Notes](#) for the architectures on which it is supported. For the purposes of clock selection, this clock can be referenced by the name "**monotonic**".

### 16.3.15.2 Clock Selection Strategy

To configure the clock selection, use the *DomainParticipant's* [47.19 PROPERTY QosPolicy \(DDS Extension\)](#) on page 837. [Table 16.7 Clock Selection Properties](#) lists the supported properties.

**Table 16.7 Clock Selection Properties**

Property	Description
dds.clock.external_clock	Comma-delimited list of clocks to use for the external clock, in the order of preference. Valid clock names are "realtime", "system", or "monotonic".
dds.clock.internal_clock	Comma-delimited list of clocks to use for the internal clock, in the order of preference. Valid clock names are "realtime", "system", or "monotonic".

By default, both the internal and external clocks use the realtime clock.

If you want your application to be robust to changes in the system time, you may use the monotonic clock as the internal clock, and leave the system clock as the external clock. However, note that this may slightly diminish performance, in that both the send and receive paths may need to get times from both clocks.

Since the monotonic clock is not available on all architectures, you may want to specify "monotonic, realtime" for the **internal\_clock** property (see [Table 16.7 Clock Selection Properties](#)). By doing so, the middleware will attempt to use the monotonic clock if it is available, and will fall back to the realtime clock if the monotonic clock is not available.

If you want the application to be robust to changes in the system time, you are not relying on source timestamps, and you want to avoid obtaining times from both clocks, you may use the monotonic clock for both the internal and external clocks.

## 16.3.16 Other DomainParticipant Operations

### 16.3.16.1 Verifying Entity Containment

If you have a handle to an *Entity*, and want to see if that *Entity* was created from your *DomainParticipant* (or any of its *Publishers* or *Subscribers*), use the **contains\_entity()** operation, which returns a boolean.

An *Entity's* instance handle may be obtained from built-in topic data (see [Accessing Discovery Information through Built-In Topics \(Chapter 28 on page 359\)](#)), various statuses, or from the **get\_instance\_handle()** operation (see [15.3 Getting an Entity's Instance Handle on page 37](#)).

### 16.3.16.2 Getting the Current Time

The `get_current_time()` operation returns the current time value from the same time-source (clock) that *Connex* uses to timestamp the data published by *DataWriters* (source\_timestamp of the SampleInfo structure, see [41.6 The SampleInfo Structure on page 676](#)). The time-sources used by *Connex* do not have to be synchronized nor are they synchronized by *Connex*.

See also: [16.3.15 Configuring the Clock per DomainParticipant on page 105](#).

### 16.3.16.3 Getting All Publishers and Subscribers

The `get_publishers()` and `get_subscribers()` operations will provide you with a list of the *DomainParticipant's Publishers* and *Subscribers*, respectively.

## 16.4 System Properties

*Connex* uses the *DomainParticipant's* PropertyQosPolicy to maintain a set of properties that provide system information, such as the hostname.

Unless the default the DDS\_DomainParticipantQos structure (see [16.3.7 Setting DomainParticipant QoS Policies on page 96](#)) is overwritten, the system properties are automatically set in the DDS\_DomainParticipantQos structure that is obtained by calling the DomainParticipantFactory's `get_default_participant_qos()` operation or by using the constant DDS\_PARTICIPANT\_QOS\_DEFAULT.

System properties are also automatically set in the DDS\_DomainParticipantQos structure loaded from an XML QoS profile unless you disable property inheritance using the attribute **inherit** in the XML tag `<property>`.

By default, the system properties are propagated to other *DomainParticipants* in the system and can be accessed through the **property** field in the [Table 28.1 Participant Built-in Topic's Data Type \(DDS\\_ParticipantBuiltinTopicData\)](#).

You can disable propagation of individual properties by setting the property's **propagate** flag to FALSE or by removing the property using the PropertyQoSPolicyHelper operation, `remove_property()` (see [Table 47.34 PropertyQoSPolicyHelper Operations](#)).

The number of system properties that are initialized for a *DomainParticipant* is platform specific: only **process\_id** and **os\_arch** are supported on all platforms.

These properties will only be created if *Connex* can obtain the information for them; see [Table 16.8 System Properties](#).

System properties are affected by the DomainParticipantResourceLimitsQoSPolicy's **participant\_property\_list\_max\_length** and **participant\_property\_string\_max\_length**.

**Table 16.8 System Properties**

Property Name	Description
dds.sys_info.creation_timestamp	Time when the executable was created. <sup>1</sup>
dds.sys_info.executable_filepath	Name and full path of the executable. <sup>2</sup>
dds.sys_info.execution_timestamp	Time when the execution started. <sup>3</sup>
dds.sys_info.hostname	Hostname <sup>4</sup>
dds.sys_info.target	Architecture for which the library was compiled (for example, x64Darwin10gcc4.2.1).
dds.sys_info.process_id	Process ID
dds.sys_info.username	Username that is running the process. <sup>5</sup>

---

<sup>1</sup>Only supported on Windows and Linux architectures.

<sup>2</sup>Only supported on Windows and Linux architectures.

<sup>3</sup>Only supported on Windows and Linux architectures.

<sup>4</sup>Supported on Windows, Linux, macOS, and QNX architectures.

<sup>5</sup>Only supported on Windows and Linux architectures.

# Part 3: Working with Data in Connex

This section includes:

- [Data Types and DDS Data Samples \(Chapter 17 on page 110\)](#)
- [Working with Topics \(Chapter 18 on page 246\)](#)
- [Working with Instances \(Chapter 19 on page 257\)](#)
- [Sample and Instance Memory Management \(Chapter 20 on page 271\)](#)
- [Mechanisms for Achieving Information Durability and Persistence \(Chapter 21 on page 288\)](#)

# Chapter 17 Data Types and DDS Data Samples

**Note:** Information in this chapter is complemented by information in the [RTI Connex Core Libraries Extensible Types Guide](#).

How data is stored or laid out in memory can vary from language to language, compiler to compiler, operating system to operating system, and processor to processor. This combination of language/compiler/operating system/processor is called a *platform*. Any modern middleware must be able to take data from one specific platform (say C/gcc 7.3/Linux/Arm v8) and transparently deliver it to another (for example, Java/JDK 11/Windows/Pentium). This process is commonly called serialization/deserialization, or marshalling/demarshalling.

Messaging products have typically taken one of two approaches to this problem:

1. **Do nothing.** Messages consist only of opaque streams of bytes. The JMS *BytesMessage* is an example of this approach.
2. **Send everything, every time.** Self-describing messages are at the opposite extreme, embedding full reflective information, including data types and field names, with each message. The JMS *MapMessage* and the messages in TIBCO Rendezvous are examples of this approach.

The “do nothing” approach is lightweight on its surface but forces you, the user of the middleware API, to consider all data encoding, alignment, and padding issues. The “send everything” alternative results in large amounts of redundant information being sent with every packet, impacting performance.

*Connex* takes an intermediate approach. Just as objects in your application program belong to some data type, DDS data samples sent on the same *Connex* topic share a data type. This type defines the fields that exist in the DDS data samples and what their constituent types are. The middleware stores and propagates this meta-information separately from the individual DDS

data samples, allowing it to propagate DDS samples efficiently while handling byte ordering and alignment issues for you.

To publish and/or subscribe to data with *Connex*, you will carry out the following steps:

1. Select a type to describe your data.

You have a number of choices. You can choose one of these options, or you can mix and match them.

- Use a built-in type provided by the middleware.

This option may be sufficient if your data typing needs are very simple. If your data is highly structured, or you need to be able to examine fields within that data for filtering or other purposes, this option may not be appropriate. The built-in types are described in [17.2 Built-in Data Types on page 121](#).

- Use the *RTI Code Generator* to define a type at compile-time using a language-independent description language.

Code generation offers two strong benefits not available with dynamic type definition: (1) it allows you to share type definitions across programming languages, and (2) because the structure of the type is known at compile time, it provides rigorous static type safety.

The *RTI Code Generator* accepts input in the following formats:

- **OMG IDL.** This format is a standardized component of the DDS specification. It describes data types with a C++-like syntax. A link to the latest specification can be found here: <https://www.omg.org/spec/IDL>. This format is described in [17.3 Creating User Data Types with IDL on page 153](#).
  - **XML in a DDS-specific format.** This XML format is terser, and therefore easier to read and write by hand, than an XSD file. It offers the general benefits of XML- extensibility and ease of integration, while fully supporting DDS-specific data types and concepts. A link to the latest specification, including a description of the XML format, can be found here: <https://www.omg.org/spec/DDS-XTypes/>. This format is described in [17.4 Creating User Data Types with Extensible Markup Language \(XML\) on page 205](#).
  - **XSD format.** You can describe data types with XML schemas (XSD). A link to the latest specification, including a description of the XSD format, can be found here: <https://www.omg.org/spec/DDS-XTypes/>. This format is described in [17.5 Creating User Data Types with XML Schemas \(XSD\) on page 215](#)
- Define a type programmatically at run time.

This method may be appropriate for applications with dynamic data description needs: applications for which types change frequently or cannot be known ahead of time. It is described in [17.8.2 Defining New Types on page 236](#).

2. Register your type with a logical name.

If you've chosen to use a built-in type instead of defining your own, you can omit this step; the middleware pre-registers the built-in types for you.

This step is described in the [17.8.2 Defining New Types on page 236](#).

3. Create a *Topic* using the type name you previously registered.

If you've chosen to use a built-in type instead of defining your own, you will use the API constant corresponding to that type's name.

Creating and working with *Topics* is discussed in [Working with Topics \(Chapter 18 on page 246\)](#).

4. Create one or more *DataWriters* to publish your data and one or more *DataReaders* to subscribe to it.

The concrete types of these objects depend on the concrete data type you've selected, in order to provide you with a measure of type safety.

Creating and working with *DataWriters* and *DataReaders* are described in [Part 5: Sending Data with Connex \(on page 370\)](#) and [Overview of Receiving Data \(Chapter 38 on page 594\)](#), respectively.

Whether publishing or subscribing to data, you will need to know how to create and delete DDS data samples and how to get and set their fields. These tasks are described in [17.9 Working with DDS Data Samples on page 240](#).

## 17.1 Introduction to the Type System

A *user data type* is any custom type that your application defines for use with *Connex*. It may be a structure, a union, a value type, an enumeration, or a typedef (or language equivalents).

Your application can have any number of user data types. They can be composed of any of the primitive data types listed below or of other user data types.

Only structures, unions, and value types may be read and written directly by *Connex*; enums, typedefs, and primitive types must be contained within a structure, union, or value type. In order for a *DataReader* and *DataWriter* to communicate with each other, the data types associated with their respective *Topic* definitions must be consistent according to the Type-Consistency Enforcement rules configured using the `TypeConsistencyEnforcementQosPolicy` on the `DataReaderQos` (see [48.6 TYPE\\_CONSISTENCY\\_ENFORCEMENT QosPolicy on page 894](#)).

- octet, char, wchar
- int16 or short, uint16 or unsigned short
- int32 or long, uint32 or unsigned long
- int64 or long long, uint64 or unsigned long long
- float
- double, long double
- boolean
- enum (with or without explicit values)
- bounded and unbounded string and wstring

The following type-building constructs are also supported:

- module (also called a *package* or *namespace*)
- pointer
- array of primitive or user type elements
- bounded/unbounded sequence of elements<sup>1</sup>—a *sequence* is a variable-length ordered collection, such as a vector or list
- typedef
- union
- struct, a complex type that supports inheritance and other object-oriented features
- value type, a deprecated type that is treated identically to a struct for backward compatibility with existing type definitions

To use a data type with *Connex*, you must define that type in a way the middleware understands and then register the type with the middleware. These steps allow *Connex* to serialize, deserialize, and otherwise operate on specific types. They will be described in detail in the following sections.

## 17.1.1 Sequences

A sequence contains an ordered collection of elements that are all of the same type. The operations supported in the sequence are documented in the API Reference HTML documentation, which is available for all supported programming languages (select **Modules**, **RTI Connex API Reference**, **Infrastructure Module**, **Sequence Support**).

---

<sup>1</sup>Sequences of sequences are not supported directly. To work around this constraint, typedef the inner sequence and form a sequence of that new type.

Java sequences implement the `java.util.List` interface from the standard Collections framework.

In the Modern C++ API, a sequence of type `T` maps to the type `std::vector<T>`, or to a type with a similar interface, depending on the options and whether it is bounded or unbounded. See [17.3.4 Translations for IDL Types on page 157](#).

Elements in a sequence are accessed with their index, just like elements in an array. Indices start at zero in all APIs except Ada. In Ada, indices start at 1. Unlike arrays, however, sequences can grow in size. A sequence has two sizes associated with it: a physical size (the "maximum") and a logical size (the "length"). The physical size indicates how many elements are currently allocated by the sequence to hold; the logical size indicates how many valid elements the sequence actually holds. The length can vary from zero up to the maximum. Elements cannot be accessed at indices beyond the current length.

A sequence may be declared as bounded or unbounded. A sequence's "bound" is the maximum number of elements that the sequence can contain at any one time. A finite bound is very important because it allows *Connex* to preallocate buffers to hold serialized and deserialized samples of your types; these buffers are used when communicating with other nodes in your distributed system. If a sequence has no bound, *Connex* will not know how large to allocate its buffers and will therefore have to allocate them on the fly as individual samples are read and written—impacting the latency and determinism of your application.

By default, any unbounded sequences found in an IDL file will be given a default bound of 100 elements. This default value can be overwritten using the *RTI Code Generator's* `-sequenceSize` command-line argument (see the [RTI Code Generator User's Manual](#)).

When using the C, C++, Java, or C# APIs, you can change the default behavior and use truly unbounded sequences by using *RTI Code Generator's* `-unboundedSupport` command-line argument. When using this option, the generated code will deserialize incoming samples as follows:

- First, it will release previous memory associated with the unbounded sequences. The memory associated with an unbounded member is not released until the sample containing the member is reused.
- Second, it will allocate new memory to accommodate the actual size of the unbounded sequences.

**To configure unbounded support for code generated with `rtiddsgen -unboundedSupport` or for `DynamicDataWriters/DynamicDataReaders` for Topics of types that contain unbounded sequences:**

1. Use these threshold QoS properties:
  - `dds.data_writer.history.memory_manager.fast_pool.pool_buffer_max_size` on the *DataWriter*

- `dds.data_reader.history.memory_manager.fast_pool.pool_buffer_max_size` on the *DataReader*
2. Set the QoS value `reader_resource_limits.dynamically_allocate_fragmented_samples` on the *DataReader* to true.
  3. For the Java API, also set these properties accordingly for the Java serialization buffer:
    - `dds.data_writer.history.memory_manager.java_stream.min_size`
    - `dds.data_writer.history.memory_manager.java_stream.trim_to_size`
    - `dds.data_reader.history.memory_manager.java_stream.min_size`
    - `dds.data_reader.history.memory_manager.java_stream.trim_to_size`

- [17.10 Data Sample Serialization Limits on page 245](#)

## 17.1.2 Strings and Wide Strings

*Connex* supports both strings consisting of single-byte characters (the IDL string type) and strings consisting of wide characters (IDL wstring). The wide characters supported by *Connex* are large enough to store two-byte Unicode/UTF16 characters.

Like sequences, strings may be bounded or unbounded. A string's "bound" is its maximum length (not counting the trailing NULL character in C and C++).

In the Modern C++ API strings map to `std::string` or to a type with a similar interface, depending on the options. See [Table 17.7 Specifying Data Types in IDL for Modern C++](#) in [17.3.4 Translations for IDL Types on page 157](#).

In C and Traditional C++, strings are mapped to `char*`. Optionally, the mapping in Traditional C++ can be changed to `std::string` by generating code with the option `-useStdString`.

By default, any unbounded string found in an IDL file will be given a default bound of 255 elements. This default value can be overwritten using the *RTI Code Generator's* `-stringSize` command-line argument (see the [RTI Code Generator User's Manual](#)).

When using the C, C++, Java, or C# APIs, you can change the default behavior and use truly unbounded strings by using *Code Generator's* `-unboundedSupport` command-line argument. When using this option, the generated code will deserialize incoming samples as follows:

- First, it will release previous memory associated with the unbounded strings. The memory associated with an unbounded member is not released until the sample containing the member is reused.
- Second, it will allocate new memory to accommodate the actual size of the unbounded strings.

**To configure unbounded support for code generated with `rtiddsgen -unboundedSupport` or for `DynamicDataWriters/DynamicDataReaders` for Topics of types that contain unbounded strings or wide strings:**

1. Use these threshold QoS properties:
  - `dds.data_writer.history.memory_manager.fast_pool.pool_buffer_max_size` on the *DataWriter*
  - `dds.data_reader.history.memory_manager.fast_pool.pool_buffer_max_size` on the *DataReader*
2. Set the QoS value `reader_resource_limits.dynamically_allocate_fragmented_samples` on the *DataReader* to true.
3. For the Java API, also set these properties accordingly for the Java serialization buffer:
  - `dds.data_writer.history.memory_manager.java_stream.min_size`
  - `dds.data_writer.history.memory_manager.java_stream.trim_to_size`
  - `dds.data_reader.history.memory_manager.java_stream.min_size`
  - `dds.data_reader.history.memory_manager.java_stream.trim_to_size`

### 17.1.2.1 IDL String Encoding

The “Extensible and Dynamic Topic Types for DDS specification” (<https://www.omg.org/spec/DDS-XTypes/>) standardizes the default encoding for strings to UTF-8. This encoding shall be used as the wire format. Language bindings may use the representation that is most natural in that particular language. If this representation is different than UTF-8, the language binding shall manage the transformation to/from the UTF-8 wire representation.

For example, in Java, IDL strings are mapped to Java String, which represents a string in the UTF-16 format. *Connex* handles the conversion to/from UTF-8 when serializing/deserializing strings in Java.

As an extension, *Connex*t offers ISO\_8859\_1 as an alternative string wire encoding.

This section describes the encoding for IDL strings across different languages in *Connex*t and how to configure that encoding.

- C, Traditional C++

IDL strings are mapped to a NULL-terminated array of DDS\_Char (char\*). Users are responsible for using the right character encoding (UTF-8 or ISO\_8859\_1) when populating the string values. This applies to all generated code, DynamicData, and Built-in data types. The middleware does not transform from the language binding encoding to the wire encoding.

- Modern C++

IDL strings are mapped to **std::string**, which contains any sequence of bytes. Users are responsible for using the right character encoding (UTF-8 or ISO\_8859\_1) when populating the string values. The middleware does not transform from the language binding encoding to the wire encoding. This applies to all generated code, DynamicData, and Built-in types.

- Ada

IDL strings are mapped to DDS.String, which is equivalent to a NULL-terminated array of DDS\_Char (char\*). Users are responsible for using the right character encoding (UTF-8 or ISO\_8859\_1) when populating the string values. The middleware does not transform from the language binding encoding to the wire encoding. This applies to all generated code and Built-in types.

- Java

IDL strings are mapped to Java String, which represents a string in the UTF-16 format. *Connex*t handles the conversion to/from UTF-8/ISO\_8859\_1 when serializing/deserializing strings. For generated code and Built-in data types, you can configure the IDL wire string encoding on a per-endpoint basis using the following properties:

- **dds.data\_reader.type\_support.cdr\_string\_encoding\_kind**
- **dds.data\_writer.type\_support.cdr\_string\_encoding\_kind**

These properties can be set at the endpoint level or the participant level. The only values currently supported are UTF-8 and ISO-8859-1. By default, the wire character encoding is assumed to be UTF-8.

For DynamicData, the user can configure the IDL wire string encoding by setting the value of **string\_character\_encoding** in DynamicDataProperty\_t. The following values are supported:

- StandardCharsets.ISO\_8859\_1
- StandardCharsets.UTF\_8 (default)

- .NET

IDL strings are mapped to **string** in C#. The conversion to/from UTF-8/ISO\_8859\_1 when serializing/deserializing strings is automatically handled by *Connex*. For generated code and built-in data types, you can configure the IDL wire string encoding on a per-endpoint basis using the following properties:

- **dds.data\_reader.type\_support.cdr\_string\_encoding\_kind**
- **dds.data\_writer.type\_support.cdr\_string\_encoding\_kind**

These properties can be set at the endpoint level or the participant level. The only values currently supported are UTF-8 and ISO-8859-1. By default, the wire character encoding is assumed to be UTF-8.

For *DynamicData*, you can configure the IDL wire string encoding by setting the value of **string\_character\_encoding** in *DynamicDataProperty\_t*. The following values are supported:

- `StringEncodingKind::UTF_8` (default)
- `StringEncodingKind::ISO_8859_1`

#### 17.1.2.1.1 Unicode Normalization when Using UTF-8 Encoding

*Connex* does not normalize the content of the IDL string fields when they are serialized and sent on the wire. It is the responsibility of the application to do that when needed.

Because the content of the string fields is not guaranteed to be normalized, by default, *Connex* normalizes the UTF-8 IDL string values and the literals they are compared with in the filter expression and/or filter parameters before the filtering evaluation occurs. The normalization affects the following features:

- `ContentFilteredTopics` (see [18.3 ContentFilteredTopics on page 256](#))
- Query conditions (see [15.9.7 ReadConditions and QueryConditions on page 66](#))
- `TopicQueries` (see [Chapter 60 Topic Queries on page 1142](#))
- `MultiChannel DataWriters` (see [Chapter 36 Multi-Channel DataWriters for High-Performance Filtering on page 576](#))

You can turn off filtering normalization by using the *DomainParticipant's* Property `Qos` property **dds-domain\_participant.filtering\_unicode\_normalization** (see [35.8 Unicode Normalization on page 566](#)).

#### 17.1.2.1.2 Filtering Character Encoding

The following filtering features use UTF-8 character encoding by default for IDL strings:

- ContentFilteredTopics (see [18.3 ContentFilteredTopics on page 256](#))
- Query conditions (see [15.9.7 ReadConditions and QueryConditions on page 66](#))
- TopicQueries (see [Chapter 60 Topic Queries on page 1142](#))
- MultiChannel *DataWriters* (see [Chapter 36 Multi-Channel DataWriters for High-Performance Filtering on page 576](#))

If the encoding of the IDL strings is ISO 8859-1, change the default filtering behavior by setting the *DomainParticipant's* Property Qos property `dds.domain_participant.filtering_character_encoding` to ISO-8859-1. For additional information about this property, see [35.7 Character Encoding on page 565](#).

### 17.1.2.2 IDL Wide Strings Encoding

The “Extensible and Dynamic Topic Types for DDS specification” (<https://www.omg.org/spec/DDS-XTypes/>) standardizes the default encoding for wide strings to UTF-16. This encoding shall be used as the wire format.

When the data representation is Extended CDR version 1, wide-string characters have a size of 4 bytes on the wire with UTF-16 encoding. When the data representation is Extended CDR version 2, wide-string characters have a size of 2 bytes on the wire with UTF-16 encoding.

Language bindings may use the representation that is most natural in that particular language. If this representation is different from UTF-16, the language binding shall manage the transformation to/from the UTF-16 wire representation.

- C, Traditional C++

IDL wide strings are mapped to a NULL-terminated array of DDS\_Wchar (DDS\_Wchar\*). DDS\_WChar is an unsigned 2-byte integer. Users are responsible for using the right character encoding (UTF-16) when populating the wide-string values. This applies to all generated code, DynamicData, and Built-in data types. *Connex* does not transform from the language binding encoding to the wire encoding.

- Modern C++

IDL wide strings are mapped to `std::wstring`, which contains a sequence of `wchar_t`. This applies to all generated code, DynamicData, and Built-in data types. When serializing/deserializing, *Connex* assumes that a `wchar_t` contains a code unit in UTF-16 encoding, even if the size of `wchar_t` is 4 bytes.

- Ada

IDL wide strings are mapped to `Standard.DDS.Wide_String`, which is a NULL-terminated array of `Standard.Wide_Character` with UTF-16 encoding. This applies to all generated code and Built-in data types.

- Java

IDL wide strings are mapped to Java String, which represents a string in the UTF-16 format. This applies to all generated code, DynamicData, and Built-in data types.

- .NET

IDL wide strings are mapped to **string** in C#. These types use the UTF-16 character encoding form. This applies to all generated code, DynamicData, and Built-in data types.

#### 17.1.2.2.1 Unicode Normalization when Using UTF-16 Encoding

*Connex* does not normalize the content of the IDL wstring fields when they are serialized and sent on the wire. It is the responsibility of the application to do that when needed.

Unlike with IDL strings, *Connex* does not normalize the UTF-16 strings used by the filtering operations, either.

### 17.1.3 Introduction to TypeCode

Type schemas—the names and definitions of a type and its fields—are represented by TypeCode objects (known as DynamicType in the Modern C++ API). A type code value consists of a type code kind (see the **TCKind** enumeration below) and a list of members. For compound types like structs and arrays, this list will recursively include one or more type code values.

```
enum TCKind {
    TK_NULL,
    TK_SHORT,
    TK_LONG,
    TK_USHORT,
    TK_ULONG,
    TK_FLOAT,
    TK_DOUBLE,
    TK_BOOLEAN,
    TK_CHAR,
    TK_OCTET,
    TK_STRUCT,
    TK_UNION,
    TK_ENUM,
    TK_STRING,
    TK_SEQUENCE,
    TK_ARRAY,
    TK_ALIAS,
    TK_LONGLONG,
    TK_ULONGLONG,
    TK_LONGDOUBLE,
    TK_WCHAR,
    TK_WSTRING,
    TK_VALUE
}
```

Type codes unambiguously match type representations and provide a more reliable test than comparing the string type names.

The **TypeCode** class, modeled after the corresponding CORBA API, provides access to type-code information. For details on the available operations for the **TypeCode** class, see the API Reference HTML documentation, which is available for all supported programming languages (select **Modules, RTI Connex API Reference, Topic Module, Type Code Support** or, for the Modern C++ API select **Modules, RTI Connex API Reference, Infrastructure Module, DynamicType and DynamicData**).

**Note:** Type-code support must be enabled if you are going to use [18.3 ContentFilteredTopics on page 256](#) with the default SQL filter. You may disable type codes and use a custom filter, as described in [35.2 Creating ContentFilteredTopics on page 548](#).

### 17.1.3.1 Sending Type Information on the Network

In addition to being used locally, the type information of a *Topic* is published automatically during discovery as part of the built-in topics for publications and subscriptions. See [28.2 Built-in DataReaders on page 360](#). This allows applications to publish or subscribe to topics of arbitrary types. This functionality is useful for generic system monitoring tools like the *rtiddspy* debug tool (see the API Reference HTML documentation).

Earlier versions of *Connex* (4.5f and lower) used serialized TypeCodes as the wire representation to communicate types over the network.

The [OMG 'Extensible and Dynamic Topic Types for DDS' specification, version 1.3](#) uses TypeObjects as the wire representation. Types are propagated by serializing the associated TypeObject representation. *Connex* 5.x and higher supports TypeObjects as the wire representation. To maintain backward compatibility with previous releases, *Connex* still supports propagation of TypeCodes; however, support for this feature may be discontinued in future releases.

If your data type has an especially complex type code, you may need to increase the value of the **type\_code\_max\_serialized\_length**, **type\_object\_max\_serialized\_length**, and **type\_object\_max\_deserialized\_length** fields in the *DomainParticipant's* [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 714](#). Or, to prevent the propagation of type information altogether, you can set these values to zero (0). Be aware that some features of monitoring tools, as well as some features of the middleware itself (such as *ContentFilteredTopics*) will not work correctly if you disable type information propagation.

For additional information on TypeCode versus TypeObject as wire representation, as well as resource limits to configure the propagation, see *Type Representation*, in the [RTI Connex Core Libraries Extensible Types Guide](#).

## 17.2 Built-in Data Types

*Connex* provides a set of standard types that are built into the middleware. These types can be used immediately; they do not require you to write IDL, use *RTI Code Generator (rtiddsgen)* (see [17.6 Using RTI Code Generator \(rtiddsgen\) on page 234](#)), or use the dynamic type API (see [17.2.7 Managing Memory for Built-in Types on page 147](#)).

The supported built-in types are **String**, **KeyedString**, **Octets**, and **KeyedOctets**. (The latter two types are called **Bytes** and **KeyedBytes**, respectively, on Java and .NET platforms.)

The built-in type API is located under the DDS namespace in Traditional C++ and .NET. For Java, the API is contained inside the package **com.rti.dds.type.builtin**. In the Modern C++ API they are located in the `dds::core` namespace.

Built-in data types are discussed in the following sections.

## 17.2.1 Registering Built-in Types

By default, the built-in types are automatically registered when a *DomainParticipant* is created. You can change this behavior by setting the *DomainParticipant*'s **dds.builtin\_type.auto\_register** property to 0 (false) using the [47.19 PROPERTY QosPolicy \(DDS Extension\) on page 837](#).

## 17.2.2 Creating Topics for Built-in Types

To create a topic for a built-in type, just use the standard *DomainParticipant* operations, **create\_topic()** or **create\_topic\_with\_profile()** (see [18.1.1 Creating Topics on page 248](#)); for the **type\_name** parameter, use the value returned by the **get\_type\_name()** operation, listed below for each API.

**Note:** In the following examples, you will see the sentinel "*<BuiltinType>*."

For C and Traditional C++: *<BuiltinType>* = String, KeyedString, Octets or KeyedOctets

For Java: *<BuiltinType>* = String, KeyedString, Bytes or KeyedBytes

### C API:

```
const char* DDS_<BuiltinType>TypeSupport_get_type_name();
```

### Traditional C++ API with namespace:

```
const char* DDS::<BuiltinType>TypeSupport::get_type_name();
```

### Traditional C++ API without namespace:

```
const char* DDS<BuiltinType>TypeSupport::get_type_name();
```

### Java API:

```
String
com.rti.dds.type.builtin.<BuiltinType>TypeSupport.get_type_name();
```

(This step is not required in the Modern C++ API or C# API)

## 17.2.2.1 Topic Creation Examples

For simplicity, error handling is not shown in the following examples.

**C Example:**

```
DDS_Topic * topic = NULL;
/* Create a builtin type Topic */
topic = DDS_DomainParticipant_create_topic(
    participant, "StringTopic",
    DDS_StringTypeSupport_get_type_name(),
    &DDS_TOPIC_QOS_DEFAULT, NULL,
    DDS_STATUS_MASK_NONE);
```

**Traditional C++ Example with namespaces:<sup>1</sup>**

```
using namespace DDS;
...
/* Create a String builtin type Topic */
Topic * topic = participant->create_topic(
    "StringTopic", StringTypeSupport::get_type_name(),
    DDS_TOPIC_QOS_DEFAULT, NULL, DDS_STATUS_MASK_NONE);
```

**Modern C++ Example:**

```
dds::topic::Topic<dds::core::StringTopicType> topic(participant, "StringTopic");
```

**C# Example:**

```
using Rti.Dds.Domain;
...
var stringTopic = participant.CreateTopic<string>("StringTopic");
```

**Java Example:**

```
import com.rti.dds.type.builtin.*;
...
/* Create a builtin type Topic */
Topic topic = participant.create_topic(
    "StringTopic", StringTypeSupport.get_type_name(),
    DomainParticipant.TOPIC_QOS_DEFAULT,
    null, StatusKind.STATUS_MASK_NONE);
```

## 17.2.3 String Built-in Type

The String built-in type is represented by a NULL-terminated character array (char \*) in C and C++ and an immutable String object in Java and. This type can be used to publish and subscribe to a single string.

### 17.2.3.1 Creating and Deleting Strings

In C and C++, *Connex* provides a set of operations to create (**DDS::String\_alloc()**), destroy (**DDS::String\_free()**), and clone strings (**DDS::String\_dup()**). Select **Modules, RTI Connex API**

---

<sup>1</sup>This example uses C++ namespaces. If you're not using namespaces in your own code, prefix the name of each DDS class with 'DDS.' For example, DDS::StringDataWriter becomes DDSStringDataWriter.

**Reference, Infrastructure Module, String support** in the API Reference HTML documentation, which is available for all supported programming languages.

### Memory Considerations in Copy Operations:

When the read/take operations that take a sequence of strings as a parameter are used in copy mode, *Connex* allocates the memory for the string elements in the sequence if they are initialized to NULL.

If the elements are not initialized to NULL, the behavior depends on the language:

- In Java and .NET, the memory associated with the elements is reallocated with every DDS sample, because strings are immutable objects.
- In C and C++, the memory associated with the elements must be large enough to hold the received data. Insufficient memory may result in crashes.

When `take_next_sample()` and `read_next_sample()` are called in C and C++, you must make sure that the input string has enough memory to hold the received data. Insufficient memory may result in crashes.

### 17.2.3.2 String DataWriter

The string *DataWriter* API matches the standard *DataWriter* API (see [31.7 Using a Type-Specific DataWriter \(FooDataWriter\) on page 409](#)). There are no extensions.

The following examples show how to write simple strings with a string built-in type *DataWriter*. For simplicity, error handling is not shown.

#### C Example:

```
DDS_StringDataWriter * stringWriter = ... ;
DDS_ReturnCode_t retCode; char * str = NULL;
/* Write some data */
retCode = DDS_StringDataWriter_write(
    stringWriter, "Hello World!", &DDS_HANDLE_NIL);
str = DDS_String_dup("Hello World!");
retCode = DDS_StringDataWriter_write(
    stringWriter, str, &DDS_HANDLE_NIL);
DDS_String_free(str);
```

**Traditional C++ Example with namespaces:<sup>1</sup>**

```
#include "ndds/ndds_namespace_cpp.h"
using namespace DDS;
...
StringDataWriter * stringWriter = ... ;
/* Write some data */
ReturnCode_t retCode = stringWriter->write(
    "Hello World!", HANDLE_NIL);
char * str = DDS::String_dup("Hello World!");
retCode = stringWriter->write(str, HANDLE_NIL);
DDS::String_free(str);
```

**Modern C++ Example:**

```
dds::pub::DataWriter<dds::core::StringTopicType> string_writer(
    participant, string_topic);
string_writer.write("Hello World!");
dds::core::string str = "Hello World!";
string_writer.write(str);
```

**C# Example:**

```
using Rti.Dds.Domain;
using Rti.Dds.Publication;
...
var stringWriter = publisher.CreateDataWriter(stringTopic);
stringWriter.Write("Hello World!");
```

**Java Example:**

```
import com.rti.dds.publication.*;
import com.rti.dds.type.builtin.*;
import com.rti.dds.infrastructure.*;
...
StringDataWriter stringWriter = ... ;
/* Write some data */
stringWriter.write(
    "Hello World!", InstanceHandle_t.HANDLE_NIL);
String str = "Hello World!";
stringWriter.write(
    str, InstanceHandle_t.HANDLE_NIL);
```

**17.2.3.3 String DataReader**

The string *DataReader* API matches the standard *DataReader* API (see [41.1 Using a Type-Specific DataReader \(FooDataReader\) on page 663](#)). There are no extensions.

The following examples show how to read simple strings with a string built-in type *DataReader*. For simplicity, error handling is not shown.

---

<sup>1</sup>This example uses C++ namespaces. If you're not using namespaces in your own code, prefix the name of each DDS class with 'DDS.' For example, `DDS::StringDataWriter` becomes `DDSStringDataWriter`.

**C Example:**

```

struct DDS_StringSeq dataSeq =
    DDS_SEQUENCE_INITIALIZER;
struct DDS_SampleInfoSeq infoSeq =
    DDS_SEQUENCE_INITIALIZER;
DDS_StringDataReader * stringReader = ... ;
DDS_ReturnCode_t retCode;
int i;
/* Take and print the data */
retCode = DDS_StringDataReader_take(
    stringReader, &dataSeq,
    &infoSeq, DDS_LENGTH_UNLIMITED,
    DDS_ANY_SAMPLE_STATE,
    DDS_ANY_VIEW_STATE,
    DDS_ANY_INSTANCE_STATE);
for (i = 0; i < DDS_StringSeq_get_length(&data_seq);
    ++i) {
    if (DDS_SampleInfoSeq_get_reference(
        &info_seq, i)->valid_data) {
        DDS_StringTypeSupport_print_data(
            DDS_StringSeq_get(&data_seq, i));
    }
}
/* Return loan */
retCode = DDS_StringDataReader_return_loan(
    stringReader, &data_seq, &info_seq);

```

**Traditional C++ Example with namespaces:<sup>1</sup>**

```

#include "ndds/ndds_namespace_cpp.h"
using namespace DDS;
...
StringSeq dataSeq;
SampleInfoSeq infoSeq;
StringDataReader * stringReader = ... ;
/* Take a print the data */
ReturnCode_t retCode = stringReader->take(
    dataSeq, infoSeq,
    LENGTH_UNLIMITED,
    ANY_SAMPLE_STATE,
    ANY_VIEW_STATE,
    ANY_INSTANCE_STATE);
for (int i = 0; i < data_seq.length(); ++i) {
    if (infoSeq[i].valid_data) {
        StringTypeSupport::print_data(dataSeq[i]);
    }
}
/* Return loan */

```

<sup>1</sup>This example uses C++ namespaces. If you're not using namespaces in your own code, prefix the name of each DDS class with 'DDS.' For example, DDS::StringDataWriter becomes DDSStringDataWriter.

```
retCode = stringReader->return_loan(  
    dataSeq, infoSeq);
```

### Modern C++ Example:

```
using namespace dds::core;  
using namespace dds::sub;  
DataReader<StringTopicType> string_reader(  
    participant, string_topic);  
LoanedSamples<StringTopicType> samples =  
    string_reader.take();  
for (auto sample : samples) {  
    if (sample.info().valid()) {  
        std::cout << sample.data() << std::endl;  
    }  
}
```

### C# Example:

```
using Rti.Dds.Domain;  
using Rti.Dds.Subscription;  
...  
var stringReader = subscriber.CreateDataReader(stringTopic);  
using LoanedSamples<string> samples = stringReader.Take();  
foreach (var sample in samples)  
{  
    if (sample.Info.ValidData)  
    {  
        Console.WriteLine(sample.Data);  
    }  
}
```

**Java Example:**

```

import com.rti.dds.infrastructure.*;
import com.rti.dds.subscription.*;
import com.rti.dds.type.builtin.*;
...
StringSeq dataSeq = new StringSeq();
SampleInfoSeq infoSeq = new SampleInfoSeq();
StringDataReader stringReader = ... ;
/* Take and print the data */
stringReader.take(
    dataSeq, infoSeq,
    ResourceLimitsQosPolicy.LENGTH_UNLIMITED,
    SampleStateKind.ANY_SAMPLE_STATE,
    ViewStateKind.ANY_VIEW_STATE,
    InstanceStateKind.ANY_INSTANCE_STATE);
for (int i = 0; i < data_seq.length(); ++i) {
    if (((SampleInfo)infoSeq.get(i)).valid_data) {
        System.out.println(
            (String)dataSeq.get(i));
    }
}
/* Return loan */
stringReader.return_loan(dataSeq, infoSeq);

```

**17.2.4 KeyedString Built-in Type**

The Keyed String built-in type is represented by a (key, value) pair, where key and value are strings. This type can be used to publish and subscribe to keyed strings. The language specific representations of the type are as follows:

**C/Traditional C++ Representation (without namespaces):**

```

struct DDS_KeyedString {
    char * key;
    char * value;
};

```

**Modern C++ Representation:**

```

class dds::core::KeyedStringTopicType {
public:
    dds::core::string& key();
    dds::core::string& value();
    // ... see API documentation for full definition
};

```

**C# Representation:**

```
namespace Rti.Types.Builtin
{
    public class KeyedStringTopicType : IEquatable<KeyedStringTopicType>
    {
        [Key]
        [Bound(1024)]
        public string Key { get; set; } = string.Empty;
        [Bound(1024)]
        public string Value { get; set; } = string.Empty;
        ...
        // ... see API documentation for full definition
    }
}
```

**Java Representation:**

```
namespace DDS {
    public class KeyedString {
        public System.String key;
        public System.String value;
    };
};
```

**17.2.4.1 Creating and Deleting Keyed Strings**

*Connex* provides a set of constructors/destructors to create/destroy Keyed Strings. For details, see the API Reference HTML documentation, which is available for all supported programming languages (select **Modules**, **RTI Connex API Reference**, **Topic Module**, **Built-in Types**).

If you want to manipulate the memory of the fields 'value' and 'key' in the KeyedString struct in C/C++, use the operations **DDS::String\_alloc()**, **DDS::String\_dup()**, and **DDS::String\_free()**, as described in the API Reference HTML documentation (select **Modules**, **RTI Connex API Reference**, **Infrastructure Module**, **String Support**).

**17.2.4.2 Keyed String DataWriter**

The keyed string *DataWriter* API is extended with the following methods (in addition to the standard methods described in [31.7 Using a Type-Specific DataWriter \(FooDataWriter\) on page 409](#)):

```
DDS::ReturnCode_t
DDS::KeyedStringDataWriter::dispose(
    const char* key,
    const DDS::InstanceHandle_t* instance_handle);
DDS::ReturnCode_t
DDS::KeyedStringDataWriter::dispose_w_timestamp(
    const char* key,
    const DDS::InstanceHandle_t* instance_handle,
    const struct DDS::Time_t* source_timestamp);
DDS::ReturnCode_t
DDS::KeyedStringDataWriter::get_key_value(
```

```

        char * key,
        const DDS::InstanceHandle_t* handle);
DDS::InstanceHandle_t
DDS::KeyedStringDataWriter::lookup_instance(
    const char * key);
DDS::InstanceHandle_t
DDS::KeyedStringDataWriter::register_instance(
    const char* key);
DDS::InstanceHandle_t
DDS_KeyedStringDataWriter::register_instance_w_timestamp(
    const char * key,
    const struct DDS_Time_t* source_timestamp);
DDS::ReturnCode_t
DDS::KeyedStringDataWriter::unregister_instance(
    const char * key,
    const DDS::InstanceHandle_t* handle);
DDS::ReturnCode_t
DDS::KeyedStringDataWriter::unregister_instance_w_timestamp(
    const char* key,
    const DDS::InstanceHandle_t* handle,
    const struct DDS::Time_t* source_timestamp);
DDS::ReturnCode_t
DDS::KeyedStringDataWriter::write (
    const char * key,
    const char * str,
    const DDS::InstanceHandle_t* handle);
DDS::ReturnCode_t
DDS::KeyedStringDataWriter::write_w_timestamp(
    const char * key,
    const char * str,
    const DDS::InstanceHandle_t* handle,
    const struct DDS::Time_t* source_timestamp);

```

These operations are introduced to provide maximum flexibility in the format of the input parameters for the write and instance management operations. For additional information and a complete description of the operations, see the API Reference HTML documentation, which is available for all supported programming languages.

The following examples show how to write keyed strings using a keyed string built-in type *DataWriter* and some of the extended APIs. For simplicity, error handling is not shown.

### C Example:

```

DDS_KeyedStringDataWriter * stringWriter = ... ;
DDS_ReturnCode_t retCode;
struct DDS_KeyedString * keyedStr = NULL;
char * str = NULL;
/* Write some data using the KeyedString structure */
keyedStr = DDS_KeyedString_new(255, 255);
strcpy(keyedStr->key, "Key 1");
strcpy(keyedStr->value, "Value 1");
retCode = DDS_KeyedStringDataWriter_write(
    stringWriter,
    keyedStr,
    &DDS_HANDLE_NIL);

```

```

DDS_KeyedString_delete(keyedStr);
/* Write some data using individual strings */
retCode = DDS_KeyedStringDataWriter_write_string_w_key(
    stringWriter, "Key 1",
    "Value 1", &DDS_HANDLE_NIL);
str = DDS_String_dup("Value 2");
retCode = DDS_KeyedStringDataWriter_write_string_w_key(
    stringWriter, "Key 1",
    str, &DDS_HANDLE_NIL);
DDS_String_free(str);

```

### C++ Example with Namespaces:<sup>1</sup>

```

#include "ndds/ndds_namespace_cpp.h"
using namespace DDS;
...
KeyedStringDataWriter * stringWriter = ... ;
/* Write some data using the KeyedString */
KeyedString * keyedStr = new KeyedString(255, 255);
strcpy(keyedStr->key, "Key 1");
strcpy(keyedStr->value, "Value 1");
ReturnCode_t retCode = stringWriter->write(
    keyedStr, HANDLE_NIL);
delete keyedStr;

```

### C# Example:

```

using Rti.Dds.Publication;
...
var keyedStringWriter = ...;
keyedStringWriter.Write(new KeyedStringTopicType(Key: "MyKey", Value: "MyValue"));

```

### Java Example:

```

import com.rti.dds.publication.*;
import com.rti.dds.type.builtin.*;
import com.rti.dds.infrastructure.*;
...
KeyedStringDataWriter stringWriter = ... ;
/* Write some data using the KeyedString */
KeyedString keyedStr = new KeyedString();
keyedStr.key = "Key 1";
keyedStr.value = "Value 1";
stringWriter.write(
    keyedStr, InstanceHandle_t.HANDLE_NIL);
/* Write some data using individual strings */
stringWriter.write(
    "Key 1", "Value 1",
    InstanceHandle_t.HANDLE_NIL);
String str = "Value 2";

```

<sup>1</sup>This example uses C++ namespaces. If you're not using namespaces in your own code, prefix the name of each DDS class with 'DDS.' For example, DDS::StringDataWriter becomes DDSStringDataWriter.

```
stringWriter.write(
    "Key 1", str,
    InstanceHandle_t.HANDLE_NIL);
```

### 17.2.4.3 Keyed String DataReader

The KeyedString *DataReader* API is extended with the following operations (in addition to the standard methods described in [41.1 Using a Type-Specific DataReader \(FooDataReader\) on page 663](#)):

```
DDS::ReturnCode_t
DDS::KeyedStringDataReader::get_key_value(
    char * key,
    const DDS::InstanceHandle_t* handle);
DDS::InstanceHandle_t
DDS::KeyedStringDataReader::lookup_instance(
    const char * key);
```

For additional information and a complete description of these operations in all supported languages, see the [API Reference HTML documentation](#), which is available for all supported programming languages.

#### Memory considerations in copy operations:

For read/take operations with copy semantics, such as `read_next_sample()` and `take_next_sample()`, *Connex* allocates memory for the fields 'value' and 'key' if they are initialized to NULL.

If the fields are not initialized to NULL, the behavior depends on the language:

- In Java and .NET, the memory associated to the fields 'value' and 'key' will be reallocated with every DDS sample.
- In C and C++, the memory associated with the fields 'value' and 'key' must be large enough to hold the received data. Insufficient memory may result in crashes.

The following examples show how to read keyed strings with a keyed string built-in type *DataReader*. For simplicity, error handling is not shown.

#### C Example:

```
struct DDS_KeyedStringSeq dataSeq =
    DDS_SEQUENCE_INITIALIZER;
struct DDS_SampleInfoSeq infoSeq =
    DDS_SEQUENCE_INITIALIZER;
DDS_KeyedKeyedStringDataReader * stringReader = ... ;
DDS_ReturnCode_t retCode;
int i;
/* Take and print the data */
retCode = DDS_KeyedStringDataReader_take(
    stringReader, &dataSeq,
    &infoSeq,
    DDS_LENGTH_UNLIMITED,
    DDS_ANY_SAMPLE_STATE,
    DDS_ANY_VIEW_STATE,
```

```

        DDS_ANY_INSTANCE_STATE);
for (i = 0;
     i < DDS_KeyedStringSeq_get_length(&data_seq);
     ++i) {
    if (DDS_SampleInfoSeq_get_reference(
        &info_seq, i)->valid_data) {
        DDS_KeyedStringTypeSupport_print_data(
            DDS_KeyedStringSeq_get_reference(&data_seq, i));
    }
}
/* Return loan */
retCode = DDS_KeyedStringDataReader_return_loan(
    stringReader, &data_seq, &info_seq);

```

### C++ Example with Namespaces:<sup>1</sup>

```

#include "ndds/ndds_namespace_cpp.h"
using namespace DDS;
...
KeyedStringSeq dataSeq;
SampleInfoSeq infoSeq;
KeyedStringDataReader * stringReader = ... ;
/* Take a print the data */
ReturnCode_t retCode = stringReader->take(
    dataSeq, infoSeq,
    LENGTH_UNLIMITED,
    ANY_SAMPLE_STATE,
    ANY_VIEW_STATE,
    ANY_INSTANCE_STATE);
for (int i = 0; i < data_seq.length(); ++i) {
    if (infoSeq[i].valid_data) {
        KeyedStringTypeSupport::print_data(&dataSeq[i]);
    }
}
/* Return loan */
retCode = stringReader->return_loan(dataSeq, infoSeq);

```

### C# Example:

```

using using Omg.Dds.Subscription;
using Rti.Dds.Subscription;
using Rti.Types.Builtin;
...
var keyedStringReader = ...;
using var samples = keyedStringReader.Take();
foreach (var sample in samples)
{
    if (sample.Info.ValidData)
    {
        Console.WriteLine(sample.Data);
    }
}

```

<sup>1</sup>This example uses C++ namespaces. If you're not using namespaces in your own code, prefix the name of each DDS class with 'DDS.' For example, DDS::StringDataWriter becomes DDSStringDataWriter.

**Java Example:**

```

import com.rti.dds.infrastructure.*;
import com.rti.dds.subscription.*;
import com.rti.dds.type.builtin.*;
...
KeyedStringSeq dataSeq = new KeyedStringSeq();
SampleInfoSeq infoSeq = new SampleInfoSeq();
KeyedStringDataReader stringReader = ... ;
/* Take and print the data */
stringReader.take(dataSeq, infoSeq,
    ResourceLimitsQosPolicy.LENGTH_UNLIMITED,
    SampleStateKind.ANY_SAMPLE_STATE,
    ViewStateKind.ANY_VIEW_STATE,
    InstanceStateKind.ANY_INSTANCE_STATE);
for (int i = 0; i < data_seq.length(); ++i) {
    if (((SampleInfo)infoSeq.get(i)).valid_data) {
        System.out.println((
            (KeyedString)dataSeq.get(i)).toString());
    }
}
/* Return loan */
stringReader.return_loan(dataSeq, infoSeq);

```

**17.2.5 Octets Built-in Type**

The octets built-in type is used to send sequences of octets. The language-specific representations are as follows:

**C/Traditional C++ Representation (without Namespaces):**

```

struct DDS_Octets {
    int length;
    unsigned char * value;
};

```

**Modern C++ Representation:**

```

class dds::core::BytesTopicType {
public:
    uint8_t& operator [] (uint32_t index);
    // ... see API documentation for full definition
};

```

**C# Representation:**

```

namespace Rti.Types.Builtin
{
    public class OctetsTopicType : IEquatable<OctetsTopicType>
    {
        public ISequence<byte> Value { get; }
        ...
    }
}

```

**Java Representation:**

```
package com.rti.dds.type.builtin;
public class Bytes implements Copyable {
    public int length;
    public int offset;
    public byte[] value;
    ...
};
```

**17.2.5.1 Creating and Deleting Octets**

*Connex* provides a set of constructors/destructors to create and destroy Octet objects. For details, see the API Reference HTML documentation, which is available for all supported programming languages (select **Modules**, **RTI Connex API Reference**, **Topic Module**, **Built-in Types**).

If you want to manipulate the memory of the value field inside the Octets struct in C/Traditional C++, use the operations `DDS::OctetBuffer_alloc()`, `DDS::OctetBuffer_dup()`, and `DDS::OctetBuffer_free()`, described in the API Reference HTML documentation (select **Modules**, **RTI Connex API Reference**, **Infrastructure Module**, **Octet Buffer Support**).

**17.2.5.2 Octets DataWriter**

(Note: for Modern C++ API, refer to the API documentation)

In addition to the standard methods (see [31.7 Using a Type-Specific DataWriter \(FooDataWriter\) on page 409](#)), the octets *DataWriter* API is extended with the following methods:

```
DDS::ReturnCode_t DDS::OctetsDataWriter::write(
    const DDS::OctetSeq & octets,
    const DDS::InstanceHandle_t & handle);
DDS::ReturnCode_t DDS::OctetsDataWriter::write(
    const unsigned char * octets,
    int length,
    const DDS::InstanceHandle_t& handle);
DDS::ReturnCode_t DDS::OctetsDataWriter::write_w_timestamp(
    const DDS::OctetSeq & octets,
    const DDS::InstanceHandle_t & handle,
    const DDS::Time_t & source_timestamp);
DDS::ReturnCode_t DDS::OctetsDataWriter::write_w_timestamp(
    const unsigned char * octets,
    int length,
    const DDS::InstanceHandle_t& handle,
    const DDS::Time_t& source_timestamp);
```

These methods are introduced to provide maximum flexibility in the format of the input parameters for the write operations. For additional information and a complete description of these operations in all supported languages, see the API Reference HTML documentation.

The following examples show how to write an array of octets using an octets built-in type *DataWriter* and some of the extended APIs. For simplicity, error handling is not shown.

**C Example:**

```

DDS_OctetsDataWriter * octetsWriter = ... ;
DDS_ReturnCode_t retCode;
struct DDS_Octets * octets = NULL;
char * octetArray = NULL;
/* Write some data using the Octets structure */
octets = DDS_Octets_new_w_size(1024);
octets->length = 2;
octets->value[0] = 46;
octets->value[1] = 47;
retCode = DDS_OctetsDataWriter_write(
    octetsWriter, octets, &DDS_HANDLE_NIL);
DDS_Octets_delete(octets);
/* Write some data using an octets array */
octetArray = (unsigned char *)malloc(1024);
octetArray[0] = 46;
octetArray[1] = 47;
retCode = DDS_OctetsDataWriter_write_octets (
    octetsWriter, octetArray, 2,
    &DDS_HANDLE_NIL);
free(octetArray);

```

**C++ Example with Namespaces:<sup>1</sup>**

```

#include "ndds/ndds_namespace_cpp.h"
using namespace DDS;
...
OctetsDataWriter * octetsWriter = ... ;
/* Write some data using the Octets structure */
Octets * octets = new Octets(1024);
octets->length = 2;
octets->value[0] = 46;
octets->value[1] = 47;
ReturnCode_t retCode = octetsWriter->write(octets, HANDLE_NIL);
delete octets;
/* Write some data using an octet array */
unsigned char * octetArray = new unsigned char[1024];
octetArray[0] = 46;
octetArray[1] = 47;
retCode = octetsWriter->write(octetArray, 2, HANDLE_NIL);
delete []octetArray;

```

---

<sup>1</sup>This example uses C++ namespaces. If you're not using namespaces in your own code, prefix the name of each DDS class with 'DDS.' For example, DDS::StringDataWriter becomes DDSStringDataWriter.

**C# Example:**

```
using Rti.Dds.Publication;
using Rti.Types.Builtin;
...
var octetsWriter = ...;
var octets = new OctetsTopicType();
octets.Value.AddRange(new byte[] { 46, 47 });
octetsWriter.Write(octets);
octets.Value[0] = 56;
octets.Value[1] = 57;
octetsWriter.Write(octets);
```

**Java Example:**

```
import com.rti.dds.publication.*;
import com.rti.dds.type.builtin.*;
import com.rti.dds.infrastructure.*;
...
BytesDataWriter octetsWriter = ... ;
/* Write some data using the Bytes class*/
Bytes octets = new Bytes(1024);
octets.length = 2;
octets.offset = 0;
octets.value[0] = 46;
octets.value[1] = 47;
octetsWriter.write(octets, InstanceHandle_t.HANDLE_NIL);
/* Write some data using a byte array */
byte[] octetArray = new byte[1024];
octetArray[0] = 46;
octetArray[1] = 47;
octetsWriter.write(octetArray, 0, 2, InstanceHandle_t.HANDLE_NIL);
```

**17.2.5.3 Octets DataReader**

(Note: for the Modern C++ API, refer to the API Reference HTML documentation)

The octets *DataReader* API matches the standard *DataReader* API (see [41.1 Using a Type-Specific DataReader \(FooDataReader\) on page 663](#)). There are no extensions.

**Memory considerations in copy operations:**

For read/take operations with copy semantics, such as **read\_next\_sample()** and **take\_next\_sample()**, *Connex* allocates memory for the field 'value' if it is initialized to NULL.

If the field 'value' is not initialized to NULL, the behavior depends on the language:

- In Java and .NET, the memory for the field 'value' will be reallocated if the current size is not large enough to hold the received data.
- In C and C++, the memory associated with the field 'value' must be big enough to hold the received data. Insufficient memory may result in crashes.

The following examples show how to read octets with an octets built-in type *DataReader*. For simplicity, error handling is not shown.

### C Example:

```
struct DDS_OctetsSeq dataSeq = DDS_SEQUENCE_INITIALIZER;
struct DDS_SampleInfoSeq infoSeq = DDS_SEQUENCE_INITIALIZER;
DDS_OctetsDataReader * octetsReader = ... ;
DDS_ReturnCode_t retCode;
int i;
/* Take and print the data */
retCode = DDS_OctetsDataReader_take(
    octetsReader, &dataSeq,
    &infoSeq, DDS_LENGTH_UNLIMITED,
    DDS_ANY_SAMPLE_STATE,
    DDS_ANY_VIEW_STATE,
    DDS_ANY_INSTANCE_STATE);
for (i = 0; i < DDS_OctetsSeq_get_length(&dataSeq); ++i) {
    if (DDS_SampleInfoSeq_get_reference(
        &infoSeq, i)->valid_data) {
        DDS_OctetsTypeSupport_print_data(
            DDS_OctetsSeq_get_reference(&dataSeq, i));
    }
}
/* Return loan */
retCode = DDS_OctetsDataReader_return_loan(
    octetsReader, &dataSeq, &infoSeq);
```

### C++ Example with Namespaces:<sup>1</sup>

```
#include "ndds/ndds_namespace_cpp.h"
using namespace DDS;
...
OctetsSeq dataSeq;
SampleInfoSeq infoSeq;
OctetsDataReader * octetsReader = ... ;
/* Take and print the data */
ReturnCode_t retCode = octetsReader->take(
    dataSeq, infoSeq,
    LENGTH_UNLIMITED, ANY_SAMPLE_STATE,
    ANY_VIEW_STATE, ANY_INSTANCE_STATE);
for (int i = 0; i < data_seq.length(); ++i) {
    if (infoSeq[i].valid_data) {
        OctetsTypeSupport::print_data(&dataSeq[i]);
    }
}
/* Return loan */
retCode = octetsReader->return_loan(dataSeq, infoSeq);
```

<sup>1</sup>This example uses C++ namespaces. If you're not using namespaces in your own code, prefix the name of each DDS class with 'DDS.' For example, DDS::StringDataWriter becomes DDSStringDataWriter.

**C# Example:**

```
using Omg.Dds.Subscription;
using Rti.Dds.Subscription;
using Rti.Types.Builtin;
...
var octetsReader = ...;
using var samples = octetsReader.Take();
foreach (var sample in samples)
{
    if (sample.Info.ValidData)
    {
        Console.WriteLine(sample.Data);
    }
}
```

**Java Example:**

```
import com.rti.dds.infrastructure.*;
import com.rti.dds.subscription.*;
import com.rti.dds.type.builtin.*;
...
BytesSeq dataSeq = new BytesSeq();
SampleInfoSeq infoSeq = new SampleInfoSeq();
BytesDataReader octetsReader = ... ;
/* Take and print the data */
octetsReader.take(dataSeq, infoSeq,
    ResourceLimitsQosPolicy.LENGTH_UNLIMITED,
    SampleStateKind.ANY_SAMPLE_STATE,
    ViewStateKind.ANY_VIEW_STATE,
    InstanceStateKind.ANY_INSTANCE_STATE);
for (int i = 0; i < data_seq.length(); ++i) {
    if (((SampleInfo)infoSeq.get(i)).valid_data) {
        System.out.println(((Bytes)dataSeq.get(i)).toString());
    }
}
/* Return loan */
octetsReader.return_loan(dataSeq, infoSeq);
```

**17.2.6 KeyedOctets Built-in Type**

The keyed octets built-in type is used to send sequences of octets with a key. The language-specific representations of the type are as follows:

**C/Traditional C++ Representation (without Namespaces):**

```
struct DDS_KeyedOctets {
    char * key;
    int length;
    unsigned char * value;
};
```

**Modern C++ Representation:**

```
class dds::core::KeyedStringTopicType {
public:
    dds::core::string& key();
    uint8_t& operator [] (uint32_t index);
    // ... see API documentation for full definition
};
```

**C# Representation:**

```
namespace Rti.Types.Builtin
{
    public class KeyedOctetsTopicType : IEquatable<KeyedOctetsTopicType>
    {
        [Key]
        [Bound(1024)]
        public string Key { get; set; } = string.Empty;
        [Bound(2048)]
        public ISequence<byte> Value { get; }
        ...
    }
}
```

**Java Representation:**

```
package com.rti.dds.type.builtin;
public class KeyedBytes {
    public String key;
    public int length;
    public int offset;
    public byte[] value;
    ...
};
```

**17.2.6.1 Creating and Deleting KeyedOctets**

*Connex* provides a set of constructors/destructors to create/destroy `KeyedOctets` objects. For details, see the API Reference HTML documentation, which is available for all supported programming languages (select **Modules**, **RTI Connex API Reference**, **Topic Module**, **Built-in Types**).

To manipulate the memory of the **value** field in the `KeyedOctets` struct in C/C++: use `DDS::OctetBuffer_alloc()`, `DDS::OctetBuffer_dup()`, and `DDS::OctetBuffer_free()`. See the API Reference HTML documentation (select **Modules**, **RTI Connex API Reference**, **Infrastructure Module**, **Octet Buffer Support**).

To manipulate the memory of the **key** field in the `KeyedOctets` struct in C/C++: use `DDS::String_alloc()`, `DDS::String_dup()`, and `DDS::String_free()`. See the API Reference HTML documentation (select **Modules**, **RTI Connex API Reference**, **Infrastructure Module**, **String Support**).

### 17.2.6.2 Keyed Octets DataWriter

In addition to the standard methods (see [31.7 Using a Type-Specific DataWriter \(FooDataWriter\) on page 409](#)), the keyed octets *DataWriter* API is extended with the following methods:

```
DDS::ReturnCode_t
DDS::KeyedOctetsDataWriter::dispose(
    const char* key,
    const DDS::InstanceHandle_t & instance_handle);
DDS::ReturnCode_t
DDS::KeyedOctetsDataWriter::dispose_w_timestamp(
    const char* key,
    const DDS::InstanceHandle_t & instance_handle,
    const DDS::Time_t & source_timestamp);
DDS::ReturnCode_t
DDS::KeyedOctetsDataWriter::get_key_value(
    char * key,
    const DDS::InstanceHandle_t& handle);
DDS::InstanceHandle_t
DDS::KeyedOctetsDataWriter::lookup_instance(
    const char * key);
DDS::InstanceHandle_t
DDS::KeyedOctetsDataWriter::register_instance(
    const char* key);
DDS::InstanceHandle_t
DDS::KeyedOctetsDataWriter::
    register_instance_w_timestamp(
        const char * key,
        const DDS::Time_t & source_timestamp);
DDS::ReturnCode_t
DDS::KeyedOctetsDataWriter::unregister_instance(
    const char * key,
    const DDS::InstanceHandle_t & handle);
DDS::ReturnCode_t
DDS::KeyedOctetsDataWriter::
unregister_instance_w_timestamp(
    const char* key,
    const DDS::InstanceHandle_t & handle,
    const DDS::Time_t & source_timestamp);
DDS::ReturnCode_t
DDS::KeyedOctetsDataWriter::write(
    const char * key,
    const unsigned char * octets,
    int length,
    const DDS::InstanceHandle_t& handle);
DDS::ReturnCode_t
DDS::KeyedOctetsDataWriter::write(
    const char * key,
    const DDS::OctetSeq & octets,
    const DDS::InstanceHandle_t & handle);
DDS::ReturnCode_t
DDS::KeyedOctetsDataWriter::write_w_timestamp(
    const char * key,
    const unsigned char * octets,
    int length,
    const DDS::InstanceHandle_t& handle,
    const DDS::Time_t& source_timestamp);
DDS::ReturnCode_t
DDS::KeyedOctetsDataWriter::write_w_timestamp(
    const char * key,
    const DDS::OctetSeq & octets,
```

```
const DDS::InstanceHandle_t & handle,
const DDS::Time_t & source_timestamp);
```

These methods are introduced to provide maximum flexibility in the format of the input parameters for the write and instance management operations. For more information and a complete description of these operations in all supported languages, see the API Reference HTML documentation.

The following examples show how to write keyed octets using a keyed octets built-in type *DataWriter* and some of the extended APIs. For simplicity, error handling is not shown.

### C Example:

```
DDS_KeyedOctetsDataWriter * octetsWriter = ... ;
DDS_ReturnCode_t retCode;
struct DDS_KeyedOctets * octets = NULL;
char * octetArray = NULL;
/* Write some data using KeyedOctets structure */
octets = DDS_KeyedOctets_new_w_size(128,1024);
strcpy(octets->key, "Key 1");
octets->length = 2;
octets->value[0] = 46;
octets->value[1] = 47;
retCode = DDS_KeyedOctetsDataWriter_write(
    octetsWriter, octets, &DDS_HANDLE_NIL);
DDS_KeyedOctets_delete(octets);
/* Write some data using an octets array */
octetArray = (unsigned char *)malloc(1024);
octetArray[0] = 46;
octetArray[1] = 47;
retCode =
DDS_KeyedOctetsDataWriter_write_octets_w_key (
    octetsWriter, "Key 1",
    octetArray, 2, &DDS_HANDLE_NIL);
free(octetArray);
```

### C++ Example with Namespaces:<sup>1</sup>

```
#include "ndds/ndds_namespace_cpp.h"
using namespace DDS;
...
KeyedOctetsDataWriter * octetsWriter = ...;
/* Write some data using KeyedOctets */
KeyedOctets * octets = new KeyedOctets(128,1024);
strcpy(octets->key, "Key 1");
octets->length = 2;
octets->value[0] = 46;
```

<sup>1</sup>This example uses C++ namespaces. If you're not using namespaces in your own code, prefix the name of each DDS class with 'DDS.' For example, DDS::StringDataWriter becomes DDSStringDataWriter.

```

octets->value[1] = 47;
ReturnCode_t retCode =
    octetsWriter->write(octets, HANDLE_NIL);
delete octets;
/* Write some data using an octet array */
unsigned char * octetArray = new unsigned char[1024];
octetArray[0] = 46;
octetArray[1] = 47;
retCode = octetsWriter->write(
    "Key 1", octetArray, 2, HANDLE_NIL);
delete []octetArray;

```

**C# Example:**

```

using Rti.Dds.Publication;
using Rti.Types.Builtin;
...
var keyedOctetsWriter = ...;
var octets = new KeyedOctetsTopicType();
octets.Key = "MyKey";
octets.Value.AddRange(new byte[] { 46, 47 });
keyedOctetsWriter.Write(octets);
octets.Value[0] = 56;
octets.Value[1] = 57;
keyedOctetsWriter.Write(octets);

```

**Java Example:**

```

import com.rti.dds.publication.*;
import com.rti.dds.type.builtin.*;
import com.rti.dds.infrastructure.*;
...
KeyedBytesDataWriter octetsWriter = ... ;
/* Write some data using KeyedBytes class */
KeyedBytes octets = new KeyedBytes(1024);
octets.key = "Key 1";
octets.length = 2;
octets.offset = 0;
octets.value[0] = 46;
octets.value[1] = 47;
octetsWriter.write(octets,
    InstanceHandle_t.HANDLE_NIL);
/* Write some data using a byte array */
byte[] octetArray = new byte[1024];
octetArray[0] = 46;
octetArray[1] = 47;
octetsWriter.write(
    "Key 1", octetArray,
    0, 2, InstanceHandle_t.HANDLE_NIL);

```

### 17.2.6.3 Keyed Octets DataReader

The KeyedOctets *DataReader* API is extended with the following methods (in addition to the standard methods described in [41.1 Using a Type-Specific DataReader \(FooDataReader\) on page 663](#)):

```
DDS::ReturnCode_t
DDS::KeyedOctetsDataReader::get_key_value(
    char * key,
    const DDS::InstanceHandle_t* handle);

DDS::InstanceHandle_t
DDS::KeyedOctetsDataReader::lookup_instance(
    const char * key);
```

For more information and a complete description of these operations in all supported languages, see the [API Reference HTML documentation](#).

#### Memory considerations in copy operations:

For read/take operations with copy semantics, such as `read_next_sample()` and `take_next_sample()`, Connexant allocates memory for the fields 'value' and 'key' if they are initialized to NULL.

If the fields are not initialized to NULL, the behavior depends on the language:

- In Java and .NET, the memory of the field 'value' will be reallocated if the current size is not large enough to hold the received data. The memory associated with the field 'key' will be reallocated with every DDS sample (the key is an immutable object).
- In C and C++, the memory associated with the fields 'value' and 'key' must be large enough to hold the received data. Insufficient memory may result in crashes.

The following examples show how to read keyed octets with a keyed octets built-in type *DataReader*. For simplicity, error handling is not shown.

#### C Example:

```
struct DDS_KeyedOctetsSeq dataSeq =
    DDS_SEQUENCE_INITIALIZER;
struct DDS_SampleInfoSeq infoSeq =
    DDS_SEQUENCE_INITIALIZER;
DDS_KeyedOctetsDataReader * octetsReader = ... ;
DDS_ReturnCode_t retCode;
int i;
/* Take and print the data */
retCode = DDS_KeyedOctetsDataReader_take(
    octetsReader,
    &dataSeq, &infoSeq, DDS_LENGTH_UNLIMITED,
    DDS_ANY_SAMPLE_STATE, DDS_ANY_VIEW_STATE,
    DDS_ANY_INSTANCE_STATE);
for (i = 0;
```

```

    i < DDS_KeyedOctetsSeq_get_length(&data_seq);
    ++i) {
    if (DDS_SampleInfoSeq_get_reference(
    &info_seq, i)->valid_data) {
        DDS_KeyedOctetsTypeSupport_print_data(
            DDS_KeyedOctetsSeq_get_reference(
                &data_seq, i));
    }
}
/* Return loan */
retCode = DDS_KeyedOctetsDataReader_return_loan(
    octetsReader, &data_seq, &info_seq);

```

### C++ Example with Namespaces:<sup>1</sup>

```

#include "ndds/ndds_namespace_cpp.h"
using namespace DDS;
...
KeyedOctetsSeq dataSeq;
SampleInfoSeq infoSeq;
KeyedOctetsDataReader * octetsReader = ... ;
/* Take and print the data */
ReturnCode_t retCode = octetsReader->take(
    dataSeq, infoSeq, LENGTH_UNLIMITED,
    ANY_SAMPLE_STATE, ANY_VIEW_STATE,
    ANY_INSTANCE_STATE);
for (int i = 0; i < data_seq.length(); ++i) {
    if (infoSeq[i].valid_data) {
        KeyedOctetsTypeSupport::print_data(
            &dataSeq[i]);
    }
}
/* Return loan */
retCode = octetsReader->return_loan(
    dataSeq, infoSeq);

```

### C# Example:

```

using Omg.Dds.Subscription;
using Rti.Dds.Subscription;
using Rti.Types.Builtin;
...
var KeyedOctetsReader = ...;
using var samples = KeyedOctetsReader.Take();
foreach (var sample in samples){
    if (sample.Info.ValidData)
    {
        Console.WriteLine(sample.Data);
    }
}

```

<sup>1</sup>This example uses C++ namespaces. If you're not using namespaces in your own code, prefix the name of each DDS class with 'DDS.' For example, DDS::StringDataWriter becomes DDSStringDataWriter.

**Java Example:**

```

import com.rti.dds.infrastructure.*;
import com.rti.dds.subscription.*;
import com.rti.dds.type.builtin.*;
...
KeyedBytesSeq dataSeq = new KeyedBytesSeq();
SampleInfoSeq infoSeq = new SampleInfoSeq();
KeyedBytesDataReader octetsReader = ... ;
/* Take and print the data */
octetsReader.take(dataSeq, infoSeq,
    ResourceLimitsQosPolicy.LENGTH_UNLIMITED,
    SampleStateKind.ANY_SAMPLE_STATE,
    ViewStateKind.ANY_VIEW_STATE,
    InstanceStateKind.ANY_INSTANCE_STATE);

for (int i = 0; i < data_seq.length(); ++i){
    if (((SampleInfo)infoSeq.get(i)).valid_data){
        System.out.println(
            ((KeyedBytes)dataSeq.get(i)).toString());
    }
}
/* Return loan */
octetsReader.return_loan(dataSeq, infoSeq);

```

**17.2.7 Managing Memory for Built-in Types**

When a DDS sample is written, the *DataWriter* serializes it and stores the result in a buffer obtained from a pool of preallocated buffers. In the same way, when a DDS sample is received, the *DataReader* deserializes it and stores the result in a DDS sample coming from a pool of preallocated DDS samples.

By default, the buffers on the *DataWriter* and the samples on the *DataReader* are preallocated with their maximum size. For example:

```

struct MyString {
    string<128> value;
};

```

This IDL-defined type has a maximum serialized size of 133 bytes (4 bytes for length + 128 characters + 1 NULL terminating character). So the serialization buffers will have a size of 133 bytes. The buffer can hold samples with 128 characters strings. Consequently, the preallocated samples will be sized to keep this length.

However, for built-in types, the maximum size of the buffers/DDS samples is unknown and depends on the nature of the application using the built-in type.

For example, a video surveillance application that is using the keyed octets built-in type to publish a stream of images will require bigger buffers than a market-data application that uses the same built-in type to publish market-data values.

To accommodate both kinds of applications and optimize memory usage, you can configure the maximum size of the built-in types on a per-*DataWriter* or per-*DataReader* basis using the [47.19](#)

[PROPERTY QosPolicy \(DDS Extension\) on page 837](#). [Table 17.1 Properties for Allocating Size of Built-in Types, per DataWriter and DataReader](#) lists the supported built-in type properties. When the properties are defined in the *DomainParticipant*, they are applicable to all *DataWriters* and *DataReaders* belonging to the *DomainParticipant*, unless they are overwritten in the *DataWriters* and *DataReaders*.

These properties must be set consistently with respect to the corresponding **\*.max\_size** properties in the *DomainParticipant* (see [Table 17.2 Properties for Allocating Size of Built-in Types, per DomainParticipant](#)). The value of the **alloc\_size** property must be less than or equal to the **max\_size** property with the same name prefix in the *DomainParticipant*.

Unbounded built-in types are only supported in the C, C++, Java, and C# APIs.

[17.2.7.1 Examples—Setting the Maximum Size for a String Programmatically on the next page](#) includes examples of how to set the maximum size of a string built-in type for a *DataWriter* programmatically, for each API. You can also set the maximum size of the built-in types using XML QoS Profiles. For example, the following XML shows how to set the maximum size of a string built-in type for a *DataWriter*.

```
<dds>
<qos_library name="BuiltinExampleLibrary">
  <qos_profile name="BuiltinExampleProfile">
    <datawriter_qos>
      <property>
        <value>
          <element>
            <name>dds.builtin_type.string.alloc_size</name>
            <value>2048</value>
          </element>
        </value>
      </property>
    </datawriter_qos>
    <datareader_qos>
      <property>
        <value>
          <element>
            <name>dds.builtin_type.string.alloc_size</name>
            <value>2048</value>
          </element>
        </value>
      </property>
    </datareader_qos>
  </qos_profile>
</qos_library>
</dds>
```

**Table 17.1 Properties for Allocating Size of Built-in Types, per DataWriter and DataReader**

Built-in Type	Property	Description
string	dds.builtin_type.string.alloc_size	Maximum size of the strings published by the DataWriter or received by the DataReader (includes the NULL-terminated character). Default: dds.builtin_type.string.max_size if defined (see <a href="#">Table 17.2 Properties for Allocating Size of Built-in Types, per DomainParticipant</a> ). Otherwise, 1024.
keyedstring	dds.builtin_type.keyed_string.alloc_key_size	Maximum size of the keys used by the DataWriter or DataReader (includes the NULL-terminated character). Default: dds.builtin_type.keyed_string.max_key_size if defined (see <a href="#">Table 17.2 Properties for Allocating Size of Built-in Types, per DomainParticipant</a> ). Otherwise, 1024.
	dds.builtin_type.keyed_string.alloc_size	Maximum size of the strings published by the DataWriter or received by the DataReader (includes the NULL-terminated character). Default: dds.builtin_type.keyed_string.max_size if defined (see <a href="#">Table 17.2 Properties for Allocating Size of Built-in Types, per DomainParticipant</a> ). Otherwise, 1024.
octets	dds.builtin_type.octets.alloc_size	Maximum size of the octet sequences published by the DataWriter or DataReader. Default: dds.builtin_type.octets.max_size if defined (see <a href="#">Table 17.2 Properties for Allocating Size of Built-in Types, per DomainParticipant</a> ). Otherwise, 2048.
keyed-octets	dds.builtin_type.keyed_octets.alloc_key_size	Maximum size of the key published by the DataWriter or received by the DataReader (includes the NULL-terminated character). Default: dds.builtin_type.keyed_octets.max_key_size if defined (see <a href="#">Table 17.2 Properties for Allocating Size of Built-in Types, per DomainParticipant</a> ). Otherwise, 1024.
	dds.builtin_type.keyed_octets.alloc_size	Maximum size of the octet sequences published by the DataWriter or DataReader. Default: dds.builtin_type.keyed_octets.max_size if defined (see <a href="#">Table 17.2 Properties for Allocating Size of Built-in Types, per DomainParticipant</a> ). Otherwise, 2048.

### 17.2.7.1 Examples—Setting the Maximum Size for a String Programmatically

For simplicity, error handling is not shown in the following examples.

#### C Example:

```

DDS_DataWriter * writer = NULL;
DDS_StringDataWriter * stringWriter = NULL;
DDS_Publisher * publisher = ... ;
DDS_Topic * stringTopic = ... ;
struct DDS_DataWriterQos writerQos =
    DDS_DataWriterQos_INITIALIZER;
DDS_ReturnCode_t retCode;
retCode = DDS_DomainParticipant_get_default_datawriter_qos (
    participant, &writerQos);
retCode = DDS_PropertyQosPolicyHelper_add_property (
    &writerQos.property,
    "dds.builtin_type.string.alloc_size", "1000",
    DDS_BOOLEAN_FALSE);
writer = DDS_Publisher_create_datawriter(
    publisher, stringTopic, &writerQos,
    NULL, DDS_STATUS_MASK_NONE);

```

```
stringWriter = DDS_StringDataWriter_narrow(writer);
DDS_DataWriterQos_finalize(&writerQos);
```

### Traditional C++ Example with Namespaces: <sup>1</sup>

```
#include "ndds/ndds_namespace_cpp.h"
using namespace DDS;
...
Publisher * publisher = ... ;
Topic * stringTopic = ... ;
DataWriterQos writerQos;
ReturnCode_t retCode =
    participant->get_default_datawriter_qos(writerQos);
retCode = PropertyQosPolicyHelper::add_property (
    &writerQos.property,
    "dds.builtin_type.string.alloc_size",
    "1000", BOOLEAN_FALSE);
DataWriter * writer = publisher->create_datawriter(
    stringTopic, writerQos,
    NULL, STATUS_MASK_NONE);
StringDataWriter * stringWriter =
    StringDataWriter::narrow(writer);
```

### Modern C++ Example:

```
dds::pub::qos::DataWriterQos writer_qos =
    participant.default_datawriter_qos();
writer_qos.policy<rtd::core::policy::Property>().set({
    "dds.builtin_type.string.alloc_size", "1000"});
dds::pub::DataWriter<dds::core::StringTopicType> writer(
    publisher, string_topic, writer_qos);
```

### C# Example:

```
using Rti.Dds.Publication;
using Rti.Types.Builtin;
...
var writerQos = participant.DefaultDataWriterQos.WithProperty(
    p => p.Add("dds.builtin_type.string.alloc_size", "1000"));
var writer = publisher.CreateDataWriter<StringTopicType>(
    publisher,
    stringTopic,
    writerQos);
```

<sup>1</sup>This example uses C++ namespaces. If you're not using namespaces in your own code, prefix the name of each DDS class with 'DDS.' For example, DDS::StringDataWriter becomes DDSStringDataWriter.

**Java Example:**

```

import com.rti.dds.publication.*;
import com.rti.dds.type.builtin.*;
import com.rti.dds.infrastructure.*;
...
Topic stringTopic = ... ;
Publisher publisher = ... ;
DataWriterQos writerQos = new DataWriterQos();
participant.get_default_datawriter_qos(writerQos);
PropertyQosPolicyHelper.add_property (
    writerQos.property,
    "dds.builtin_type.string.alloc_size",
    "1000", false);
StringDataWriter stringWriter =
    (StringDataWriter) publisher.create_datawriter(
        stringTopic, writerQos,
        null, StatusKind.STATUS_MASK_NONE);

```

**17.2.7.2 Unbounded Built-in Types**

In some scenarios, the maximum size of a built-in type is not known in advance and there is no reasonable maximum size. For example, this could occur in a file transfer application using the built-in type Octets. Setting a large value for the **dds.builtin\_type.\*.alloc\_size** property would involve high memory usage.

**Note:** Replace *\** with one of the built-in type names. See [Table 17.1 Properties for Allocating Size of Built-in Types, per DataWriter and DataReader](#) for the full property names.

For the above use case, you can configure the built-in type to be unbounded by setting the property **dds.builtin\_type.\*.alloc\_size** to the maximum value of a 32-bit signed integer: 2,147,483,647. Then the middleware will not preallocate the *DataReader* queue's samples to their maximum size. Instead, it will deserialize incoming samples by dynamically allocating and deallocating memory to accommodate the actual size of the sample value.

**To configure unbounded support for built-in types:**

1. Use these threshold QoS properties:
  - **dds.data\_writer.history.memory\_manager.fast\_pool.pool\_buffer\_max\_size** on the *DataWriter*
  - **dds.data\_reader.history.memory\_manager.fast\_pool.pool\_buffer\_max\_size** on the *DataReader*
2. Set the QoS value **reader\_resource\_limits.dynamically\_allocate\_fragmented\_samples** on the *DataReader* to true.

3. For the Java API, also set these properties accordingly for the Java serialization buffer:

- **dds.data\_writer.history.memory\_manager.java\_stream.min\_size**
- **dds.data\_writer.history.memory\_manager.java\_stream.trim\_to\_size**
- **dds.data\_reader.history.memory\_manager.java\_stream.min\_size**
- **dds.data\_reader.history.memory\_manager.java\_stream.trim\_to\_size**

See these sections:

- [20.1.3 Writer-Side Memory Management when Using Java on page 276](#)
- [20.2.2 Reader-Side Memory Management when Using Java on page 280](#)

Unbounded built-in types are only supported in the C, C++, .NET, and Java APIs.

## 17.2.8 Type Codes for Built-in Types

The type codes associated with the built-in types are generated from the following IDL type definitions:

```
module DDS {
  /* String */
  struct String {
    string<max_size> value;
  };
  /* KeyedString */
  struct KeyedString {
    @key string<max_size> key;
    string<max_size> value;
  };
  /* Octets */
  struct Octets {
    sequence<octet, max_size> value;
  };
  /* KeyedOctets */
  struct KeyedOctets {
    @key string<max_size> key;
    sequence<octet, max_size> value;
  };
};
```

The maximum size (**max\_size**) of the strings and sequences that will be included in the type code definitions can be configured on a per-*DomainParticipant*-basis by using the properties in [Table 17.2 Properties for Allocating Size of Built-in Types, per DomainParticipant](#).

**Table 17.2 Properties for Allocating Size of Built-in Types, per DomainParticipant**

Built-in Type	Property	Description
String	dds.builtin_type.string.max_size	Maximum size of the strings published by the <i>DataWriters</i> and received by the <i>DataReaders</i> belonging to a <i>DomainParticipant</i> (includes the NULL-terminated character). Default: 1024
KeyedString	dds.builtin_type.keyed_string.max_key_size	Maximum size of the keys used by the <i>DataWriters</i> and <i>DataReaders</i> belonging to a <i>DomainParticipant</i> (includes the NULL-terminated character). Default: 1024
	dds.builtin_type.keyed_string.max_size	Maximum size of the strings published by the <i>DataWriters</i> and received by the <i>DataReaders</i> belonging to a <i>DomainParticipant</i> using the built-in type (includes the NULL-terminated character). Default: 1024
Octets	dds.builtin_type.octets.max_size	Maximum size of the octet sequences published by the <i>DataWriters</i> and <i>DataReaders</i> belonging to a <i>DomainParticipant</i> . Default: 2048
Keyed-Octets	dds.builtin_type.keyed_octets.max_key_size	Maximum size of the key published by the <i>DataWriter</i> and received by the <i>DataReaders</i> belonging to the <i>DomainParticipant</i> (includes the NULL-terminated character). Default: 1024.
	dds.builtin_type.keyed_octets.max_size	Maximum size of the octet sequences published by the <i>DataWriters</i> and <i>DataReaders</i> belonging to a <i>DomainParticipant</i> . Default: 2048

## 17.3 Creating User Data Types with IDL

You can create user data types in a text file using IDL (Interface Description Language). IDL is programming-language independent, so the same file can be used to generate code in C, Traditional C++, Modern C++, Ada, and Java (the languages supported by *RTI Code Generator* (*rtiddsgen*)). *RTI Code Generator* parses the IDL file and automatically generates all the necessary routines and wrapper functions to bind the types for use by *Connex* at run time. You will end up with a set of required routines and structures that your application and *Connex* will use to manipulate the data.

*Connex* only uses a subset of the IDL 4.2 (<https://www.omg.org/spec/IDL>) syntax. IDL was originally defined by the OMG for the use of CORBA client/server applications in an enterprise setting. Not all of the constructs that can be described by the language are as useful in the context of high-performance data-centric embedded applications. These include the constructs that define method and function prototypes like “interface.”

*RTI Code Generator* will parse any file that follows version 4.2 of the IDL specification. It will ignore and show a warning for all syntax that is not recognized by *Connex*. There is a limit of 256 characters for the length of a variable name in an IDL file.

Certain keywords are considered reserved by the IDL specification; see [Table 17.3 Reserved IDL Keywords](#).

**Note:** [Table 17.3 Reserved IDL Keywords](#) does not include other words that may be used by macros for different compilers and operating systems. For example, *min* and *max* are reserved keywords for Microsoft Visual Studio 2015.

**Table 17.3 Reserved IDL Keywords**

abstract	any	alias	attribute	bitfield
bitmask	bitset	boolean	case	char
component	connector	const	consumes	context
custom	default	double	exception	emits
enum	eventtype	factory	FALSE	finder
fixed	float	getraises	home	import
in	inout	interface	local	long
manages	map	mirrorport	module	multiple
native	Object	octet	oneway	out
primarykey	private	port	porttype	provides
public	publishes	raises	readonly	setraises
sequence	short	string	struct	supports
switch	TRUE	truncatable	typedef	typeid
typename	typeprefix	unsigned	union	uses
ValueBase	valuetype	void	wchar	wstring
int8	uint8	int16	int32	int64
uint16	uint32	uint64		

The IDL constructs supported by *RTI Code Generator* are described in [Table 17.5 Specifying Data Types in IDL for C](#) through [Table 17.9 Specifying Data Types in IDL for Java](#). Use these tables to map primitive types to their equivalent IDL syntax, and vice versa.

For C and Traditional C++, *RTI Code Generator* uses typedefs instead of the language keywords for primitive types. For example, `DDS_Long` instead of `long` (or `int32`) or `DDS_Double` instead of `double`. This ensures that the types are of the same size regardless of the platform.

The number of bytes sent on the wire for each data type is determined by the Common Data Representation (CDR) defined in the [OMG 'Extensible and Dynamic Topic Types for DDS' specification, version 1.3](#). There are two different CDR representations, encoding version 1 and encoding version 2. *Connex* implements both. See the [RTI Connex Core Libraries Extensible Types Guide](#) for more information.

## 17.3.1 Variable-Length Types

When *RTI Code Generator* generates code for data structures with variable-length types—strings and sequences—it includes functions that create, initialize and finalize (destroy) those objects. These support functions will properly initialize pointers and allocate and deallocate the memory used for variable-length types. All *Connex* APIs assume that the data structures passed to them are properly initialized.

For variable-length types, the actual length (instead of the maximum length) of data is transmitted on the wire when the DDS sample is written (regardless of whether the type has hard-coded bounds).

### 17.3.1.1 Sequences

In C, Traditional C++, C#, and Ada, sequences provide the concept of memory "ownership." A sequence may own the memory allocated to it or be loaned memory from another source. If a sequence owns its memory, it will manage its underlying memory storage buffer itself. When a sequence's maximum size is changed, the sequence will free and reallocate its buffer as needed. However, if a sequence was created with loaned memory by user code, then its memory is not its own to free or reallocate. Therefore, you cannot set the maximum size of a sequence whose memory is loaned. See the API Reference HTML documentation (select Modules, RTI Connex API Reference, Infrastructure Module, Sequence Support) for more information about how to loan and unloan memory for sequence.

In IDL, as described above, a sequence may be declared as bounded or unbounded. A sequence's "bound" is the greatest value its maximum may take. If you use the initializer functions *RTI Code Generator* provides for your types, all sequences will have their maximums set to their declared bounds. However, the amount of data transmitted on the wire when the DDS sample is written will vary.

In the Modern C++ and Java APIs, sequences always own the memory.

### 17.3.1.2 Strings and Wide Strings

**Note:** This section doesn't apply to the Modern C++ API, where strings map to `std::string` or `dds::core::string`, which behaves similarly. It also does not apply to the Traditional C++ API when generating code with the option `-useStdString`, which maps strings to `std::string`.

The initialization functions that *RTI Code Generator* provides for your types will allocate all of the memory for strings in a type to their declared bounds. Take care—if you assign a string pointer (`char *`) in a data structure allocated or initialized by a *Connex*-generated function, you should release (free) the memory originally allocated for the string, otherwise the memory will be leaked.

To Java and .NET users, an IDL string is a `String` object: it is immutable and knows its own length. C and C++ users must take care, however, as there is no way to determine how much memory is allocated to a character pointer "string"; all that can be determined is the string's current logical length. In some cases, *Connex* may need to copy a string into a structure that user code has provided. *Connex* does not free the memory of the string provided to it, as it cannot know from where that memory was allocated.

In the C and C++ APIs, *Connex* therefore uses the following conventions:

- A string's memory is "owned" by the structure that contains that string. Calling the finalization function provided for a type will free all recursively contained strings. If you have allocated a contained string in a special way, you must be careful to clean up your own memory and assign the pointer to NULL *before* calling the type's **finalize()** method, so that *Connex* will skip over that string.
- You must provide a non-NULL string pointer for *Connex* to copy into. Otherwise, *Connex* will log an error.
- When you provide a non-NULL string pointer in your data structure, *Connex* will copy into the provided memory without performing any additional memory allocations. Be careful—if you provide *Connex* with an uninitialized pointer or allocate a string that is too short, you may corrupt the memory or cause a program crash. *Connex* will never try to copy a string that is longer than the bound of the destination string. However, your application must insure that any string that it allocates is long enough.

*Connex* provides a small set of C functions for dealing with strings. These functions simplify common tasks, avoid some platform-specific issues (such as the lack of a **strdup()** function on some platforms), and provide facilities for dealing with wide strings, for which no standard C library exists. *Connex* always uses these functions internally for managing string memory; you are recommended—but not required—to use them as well. See the API Reference HTML documentation, which is available for all supported programming languages (select **Modules, RTI DDS API Reference, Infrastructure Module, String Support**) for more information about strings.

## 17.3.2 Value Types

With the addition of inheritance to structs in *Connex* 5.0, value types are considered equivalent to structs. It is recommended to use structures instead of value types, since the valuetype construct may not be supported in future releases. For additional information, see *Structure Inheritance, in the Type System Enhancements* chapter of the [RTI Connex Core Libraries Extensible Types Guide](#).

Readers familiar with value types in the context of CORBA should consult [Table 17.4 Value Type Support](#) to see which value type-related IDL keywords are supported and what their behavior is in the context of *Connex*.

**Table 17.4 Value Type Support**

Aspect	Level of Support in RTI Code Generator
Inheritance	Single inheritance from other value types
Public state members	Supported

**Table 17.4 Value Type Support**

Aspect	Level of Support in RTI Code Generator
Private state members	Become public when code is generated
Custom keyword	Ignored (the value type is parsed without the keyword and code is generated to work with it)
Abstract value types	No code generated (the value type is parsed, but no code is generated)
Operations	No code generated (the value type is parsed, but no code is generated)
Truncatable keyword	Ignored (the value type is parsed without the keyword and code is generated to work with it)

### 17.3.3 Type Codes

Type codes are always enabled when you run *RTI Code Generator*. Locally, your application can access the type code for a generated type "Foo" by calling the **FooTypeSupport::get\_typecode()** (Traditional C++ Notation) operation in the code for the type generated by *RTI Code Generator*.

### 17.3.4 Translations for IDL Types

This section describes how to specify your data types in an IDL file. *RTI Code Generator* supports all the types listed in the following tables:

- [Table 17.5 Specifying Data Types in IDL for C](#)
- [Table 17.6 Specifying Data Types in IDL for Traditional C++](#)
- [Table 17.7 Specifying Data Types in IDL for Modern C++](#)
- [Table 17.8 Specifying Data Types in IDL for C#](#)
- [Table 17.9 Specifying Data Types in IDL for Java](#)
- [Table 17.10 Specifying Data Types in IDL for Ada](#)
- [Table 17.11 Specifying Data Types in IDL for Python](#)

In each table, the middle column shows the IDL syntax for a data type in an IDL file. The rightmost column shows the corresponding language mapping created by *RTI Code Generator*.

Table 17.5 Specifying Data Types in IDL for C

IDL Type	Example Entry in IDL File	Example Output Generated by RTI Code Generator (rtiddsgen)
char (see <a href="#">Note 1</a> below)	<pre>struct PrimitiveStruct {     char char_member; };</pre>	<pre>typedef struct PrimitiveStruct {     DDS_Char char_member; } PrimitiveStruct;</pre>

**Notes for the above tables:**

**Note 1:** In C and C++, primitive types are not represented as native language types (e.g. long, char, etc.) but as custom types in the DDS namespace (DDS\_Long, DDS\_Char, etc.). These typedefs are used to ensure that a field's size is the same across platforms.

**Note 2:** Some platforms do not support long double or have different sizes for that type than defined by IDL (16 bytes). On such platforms, DDS\_LongDouble (as well as the unsigned version) is mapped to a character array that matches the expected size of that type by default.

If you are using a platform whose native mapping has exactly the expected size,

you can instruct *Connex*t to use the native type instead. That is, if `sizeof(long double) == 16`, you can tell *Connex*t to map `DDS_LongDouble` to long double by defining the following macro either in code or on the compile line:

```
-DRTI_CDR_SIZEOF_LONG_DOUBLE=16
```

- Note 3:** Unions in IDL are mapped to structs in C, C++ and records in ADA, so that *Connex*t will not have to dynamically allocate memory for unions containing variable-length fields such as strings or sequences. To be efficient, the entire struct is not sent when the union is published. Instead, *Connex*t uses the discriminator field of the struct to decide what field in the struct is actually sent on the wire.
- Note 4:** So-called "anonymous sequences" —sequences of sequences in which the sequence element has no type name of its own—are not supported in IDL. For example, this is *not* supported:
- ```
sequence<sequence<short, 4>, 4> MySequence;
```
- Sequences of typedef'ed types, where the typedef is really a sequence, are supported.
- For example, this is supported:
- ```
typedef sequence<short, 4> MyShortSequence;
sequence<MyShortSequence, 4> MySequence;
```
- Note 5:** IDL `wchar` and `char` are mapped to Java `char`, 16-bit unsigned quantities representing Unicode characters as specified in the standard OMG IDL to Java mapping.
- Note 6:** The unsigned version for integer types is mapped to its signed version as specified in the standard OMG IDL to Java mapping.
- Note 7:** There is no current support in Java for the IDL long double type. This type is mapped to double as specified in the standard OMG IDL to Java mapping.
- Note 8:** Java does not have a typedef construct. Typedefs for types that are neither arrays nor sequences (struct, unions, strings, wstrings, primitive types and enums) are "unwound" to their original type until a simple IDL type or user-defined IDL type (of the non-typedef variety) is encountered. For typedefs of sequences or arrays, *RTI Code Generator* will generate wrapper classes.
- Note 9:** See [17.3.9.4 The @external Annotation on page 200](#).
- Note 10:** In-line nested types are not supported inside structures, unions or valuetypes. For example, this is *not* supported:

```
struct Outer {
    short outer_short;
    struct Inner {
        char inner_char;
        short inner_short;
    } outer_nested_inner;
};
```

**Note 11:** The sequence <Type>Seq is implicitly declared in the IDL file and therefore it cannot be declared explicitly by the user. For example, this is not supported:

```
typedef sequence<Foo> FooSeq; //error
```

However, if *RTI Code Generator's* option, `-typeSequenceSuffix <Suffix>`, is used and the <Suffix> is not 'Seq', the sequence would be:

```
typedef sequence<Foo> Foo<Suffix>; //no error
```

**Note 12:** *RTI Code Generator* will supply a default bound for sequences and strings. You can specify that bound with the `-sequenceSize` or `-stringSize` command-line option, respectively. See the [RTI Code Generator User's Manual](#).

**Note 13:** In ADA, primitive types are not represented as native language types (e.g., Character, etc.) but as custom types in the DDS namespace (Standard.DDS.Long, Standard.DDS.Char, etc.). These typedefs are used to ensure that a field's size is the same across platforms.

**Note 14:** Every type provides a default constructor, a copy constructor, a move constructor, a constructor with parameters to set all the type's members, a destructor, a copy-assignment operator, and a move-assignment operator. Types also include equality operators, the operator << and a namespace-level swap function.

```
PrimitiveStruct();
explicit PrimitiveStruct(char char_member);
PrimitiveStruct(PrimitiveStruct&& other_) OMG_NOEXCEPT;
PrimitiveStruct& operator=(PrimitiveStruct&& other_) OMG_NOEXCEPT;
bool operator == (const PrimitiveStruct& other_) const;
bool operator != (const PrimitiveStruct& other_) const;
void swap(PrimitiveStruct& other_) OMG_NOEXCEPT ;
std::ostream& operator << (std::ostream& o, const PrimitiveStruct& sample);
```

**Note 15:** Sequences of pointers are not supported. For example, this is NOT supported:

```
sequence<long*, 100>;
```

Sequences of typedef'ed types, where the typedef is really a pointer, are supported. For example, this is supported:

```
typedef long* pointerToLong;
sequence<pointerToLong, 100>;
```

**Note 16:** int8 and uint8 are supported only at the API level. They are still considered octets for type matching purposes.

## 17.3.5 Escaped Identifiers

To use an IDL keyword as an identifier, the keyword must be “escaped” by prepending an underscore, ‘\_’. In addition, you must run *RTI Code Generator* with the **-enableEscapeChar** option. For example:

```
struct MyStruct {
    octet _octet; // octet is a keyword. To use the type
                // as a member name we add '_'
};
```

The use of ‘\_’ is a purely lexical convention that turns off keyword checking. The generated code will not contain ‘\_’. For example, the mapping to C would be as follows:

```
struct MyStruct {
    unsigned char octet;
};
```

**Note:** If you generate code from an IDL file to a language ‘X’ (for example, C++), the keywords of this language cannot be used as IDL identifiers, even if they are escaped. For example:

```
struct MyStruct {
    int32 int; // error
    int32 _int; // error
};
```

## 17.3.6 Namespaces In IDL Files

In IDL, the **module** keyword is used to create namespaces for the declaration of types defined within the file.

Here is an example IDL definition:

```
module PackageName {
    struct Foo {
        int32 field;
    };
};
```

### C Mapping:

The name of the module is concatenated to the name of the structure to create the namespace. The resulting code looks like this:

```
typedef struct PackageName_Foo {
    DDS_Long field;
} PackageName_Foo;
```

**C++ Mapping:**

In the Traditional C++ API, when using the **-namespace** command-line option, *RTI Code Generator* generates a namespace, such as the following:

```
namespace PackageName{
    class Foo {
        public:
            DDS_Long field;
    }
}
```

Without the **-namespace** option, the mapping adds the module to the name of the class:

```
class PackageName_Foo {
    public:
        DDS_Long field;
}
```

In the Modern C++ API, namespaces are always used.

**Java Mapping:**

A **Foo.java** file will be created in a directory called **PackageName** to use the equivalent concept as defined by Java. The file **PackageName/Foo.java** will contain a declaration of Foo class:

```
package PackageName;
public class Foo {
    public int field;
};
```

In a more complex example, consider the following IDL definition:

```
module PackageName {
    struct Bar {
        int32 field;
    };
    struct Foo {
        Bar barField;
    };
};
```

When *RTI Code Generator* generates code for the above definition, it will resolve the **Bar** type to be within the scope of the **PackageName** module and automatically generate fully qualified type names.

**C Mapping:**

```
typedef struct PackageName_Bar {
    DDS_Long field;
} PackageName_Bar;
typedef struct PackageName_Foo {
    PackageName_Bar barField;
} PackageName_Foo;
```

**C++ Mapping:****With -namespace:**

```
namespace PackageName {
    class Bar {
        public:
            DDS_Long field;
    };
    class Foo {
        public:
            PackageName::Bar barField;
    };
};
```

**Without -namespace:**

```
class PackageName_Bar {
    public:
        DDS_Long field;
};
class PackageName_Foo {
    public:
        PackageName_Bar barField;
};
```

**Java Mapping:**

**PackageName/Bar.java** and **PackageName/Foo.java** would be created with the following code, respectively:

```
package PackageName;
public class Bar {
    public
        int field;
};

package PackageName;
public class Foo {
    public
        PackageName.Bar barField = PackageName.Bar.create();
};
```

**17.3.7 Referring to Other IDL Files**

IDL files may refer to other IDL files using a syntax borrowed from C or C++ preprocessors. For example:

**Bar.idl**

```
struct Bar {
};
```

**Foo.idl**

```
#include "Bar.idl"
struct Foo {
    Bar m1;
};
```

The parsing of **Foo** in the above scenario will be successful, since **Bar** can be found in **Bar.idl**. (If **Bar** was not declared in **Bar.idl**, *Code Generator* would report an error indicating that the symbol could not be found.)

When *Code Generator* uses the default preprocessor, it will look for the included files, in this example, **Bar.idl**, in the following directories and in this order:

1. Path designated by the operating system for temporary files (e.g., /tmp/ in Linux).
2. Working directory where *Code Generator* was executed.
3. Directory or directories specified by the user using the **-I** command-line option (if any).
4. Directory where the input file is.
5. Default C++ preprocessor's include directories (cpp -v /dev/null -o /dev/null).

Please note that when invoking *Code Generator* and specifying **Foo.idl** as a parameter, only the data types defined *in that file* will be generated. If **Foo.idl** includes another file, such as **Bar.idl**, you would also need to invoke *Code Generator* using **Bar.idl** as a parameter.

If *Code Generator* encounters an **#include** statement and you are generating code for C or C++, *Code Generator* will assume that code has been generated for **Bar.idl** with corresponding header files, **Bar.h** and **BarPlugin.h**.

The generated code will automatically add these files where needed in the **Foo** generated code, in order to compile correctly:

```
#include "Bar.h"
#include "BarPlugin.h"
```

Because Java types do not refer to one another in the same way, it is not possible for *Code Generator* to automatically generate Java import statements based on an IDL **#include** statement. **#include** statements will not generate any specific code when Java code is generated. To add imports to your generated Java code, you should use the **@copy** directive (see [17.3.9.5 The @copy and Related Annotations on page 200](#)).

## 17.3.8 Preprocessor Directives

*RTI Code Generator* supports the standard preprocessor directives defined by the IDL specification, such as **#if**, **#endif**, **#include**, and **#define**.

To support these directives, *RTI Code Generator* calls an external C preprocessor before parsing the IDL file. On Windows systems, the preprocessor is 'cl.exe.' On other architectures, the preprocessor is 'cpp.' You can change the default preprocessor with the `-ppPath` option. If you do not want to run the preprocessor, use the `-ppDisable` option (see the [RTI Code Generator User's Manual](#)).

## 17.3.9 Using Builtin Annotations

*RTI Code Generator* supports the following builtin annotations, which can be used in your IDL File:

- Described in this document:
  - [@key \(17.3.9.1 The @key Annotation on the next page\)](#)
  - [@nested \(17.3.9.2 The @nested Annotation on page 199\)](#)
  - [@value \(17.3.9.3 The @value Annotation on page 200\)](#)
  - [@external \(17.3.9.4 The @external Annotation on page 200\)](#)
- Described in the [RTI Connex Core Libraries Extensible Types Guide](#):
  - @extensibility
  - @id
  - @hashid
  - @autoid
  - @optional
  - @appendable
  - @mutable
  - @final
  - @default
  - @default\_literal
  - @min
  - @max
  - @range
  - @data\_representation (or @allowed\_data\_representation)

These annotations are described in two standard documents: [OMG 'Interface Definition Language' specification, version 4.2](#) and [OMG 'Extensible and Dynamic Topic Types for DDS' specification, version 1.3](#).

In addition, RTI provides the following RTI-specific annotations:

- [@copy \(17.3.9.5 The @copy and Related Annotations on page 200\)](#)
- [@resolve\\_name \(17.3.9.6 The @resolve\\_name Annotation on page 202\)](#)
- [@use\\_vector \(17.3.9.7 The @use\\_vector annotation on page 203\)](#)
- [@top\\_level \(Replaced by @nested. See 17.3.9.2 The @nested Annotation on the next page.\)](#)

### 17.3.9.1 The @key Annotation

To declare a key for your data type, insert the `@key` annotation in the IDL file before one or more fields of the data type.

With each key, *Connex* associates an internal 16-byte representation, called a *key-hash*.

If the maximum size of the serialized key is greater than 16 bytes, to generate the key-hash, *Connex* computes the MD5 key-hash of the serialized key in network-byte order. Otherwise (if the maximum size of the serialized key is  $\leq 16$  bytes), the key-hash is the serialized key in network-byte order.

Only **struct** and **valuetype** definitions in IDL may have key fields. When *RTI Code Generator* encounters `@key`, it considers the annotated field in the enclosing structure or valuetype to be part of the key. [Table 17.12 Example Keys](#) shows some examples of keys.

**Table 17.12 Example Keys**

Type	Key Fields
<pre>struct NoKey {     int32 member1;     int32 member2; }</pre>	
<pre>struct SimpleKey {     @key int32 member1;     int32 member2; }</pre>	member1
<pre>struct NestedNoKey {     SimpleKey member1;     int32 member2; }</pre>	
<pre>struct NestedKey {     @key SimpleKey member1;     int32 member2; }</pre>	member1.member1
<pre>struct NestedKey2 {     @key NoKey member1;     int32 member2; }</pre>	member1.member1 member1.member2
<pre>valuetype BaseValueKey {     @key public int32 member1; }</pre>	member1

Table 17.12 Example Keys

Type	Key Fields
<pre> valuetype DerivedValueKey :BaseValueKey {     @key public int32 member2; } </pre>	member1 member2
<pre> valuetype DerivedValue : BaseValueKey {     public int32 member2; } </pre>	member1
<pre> struct ArrayKey {     @key int32 member1[3]; } </pre>	member1[0] member1[1] member1[2]

### 17.3.9.2 The @nested Annotation

By default, *RTI Code Generator* generates user-level type-specific methods for all structures/unions found in an IDL file. These methods include the methods used by *DataWriters* and *DataReaders* to send and receive data of a given type. General methods for writing and reading that take a void pointer are not offered by *Connexr* because they are not type safe. Instead, type-specific methods must be created to support a particular data type.

We use the term ‘top-level type’ to refer to the data type for which you intend to create a *Topic* that can be published or subscribed to. For top-level types, *RTI Code Generator* must create all of the type-specific methods previously described in addition to the code to serialize/deserialize those types. However, some of structures/unions defined in the IDL file are only embedded within higher-level structures and are not meant to be published or subscribed to individually. For non-top-level types, the *DataWriters* and *DataReaders* methods to send or receive data of those types are superfluous and do not need to be created. Although the existence of these methods is not a problem in and of itself, code space can be saved if these methods are not generated in the first place.

You can mark non-top-level types in an IDL file with the annotation `@nested` to tell *RTI Code Generator* not to generate type-specific methods. Code will still be generated to serialize and deserialize those types, since they may be embedded in top-level types.

The top-level directive can also be used but with the opposite meaning. `@top_level` or `//@top-level` (true) indicates that the type is top level, therefore, `@top_level` (false) would be equivalent to `@nested`.

In this example, *RTI Code Generator* will generate *DataWriter/DataReader* code for `TopLevelStruct` only:

```

@nested
struct EmbeddedStruct {
    int16 member;
};

```

```
struct TopLevelStruct{
    EmbeddedStruct member;
};
```

### 17.3.9.3 The @value Annotation

The @value annotation can be used to set specific values to members of enumerations. For example:

```
enum MyEnum {
    @value (17) e17,
    @value (2) e2,
    @value (3) e3
}
```

It is equivalent to:

```
enum MyEnum {
    e17 =17,
    e2 = 2,
    e3 =3
}
```

### 17.3.9.4 The @external Annotation

A member declared as external using the @external annotation (or the \* modifier) within an aggregated type indicates that it is desirable for the implementation to store the member in storage external to the enclosing aggregated type object.

For example:

```
struct MyStruct {
    @external int32 member;
}
```

This is equivalent to the following structure, although the usage of the @external annotation is preferred because it is standard:

```
struct MyStruct {
    int32 *member;
};
```

The @external annotation only has effect in C, C++, Modern C++, and Ada applications where the members will be mapped to references (pointers). In other languages, the annotation is ignored because the members are always mapped as references.

In Modern C++ the annotation maps to the type `dds::core::external<T>`, a type similar to `shared_ptr`.

### 17.3.9.5 The @copy and Related Annotations

To copy a line of text verbatim into the generated code files, use the @copy annotation in the IDL file. The @copy annotation can only be applied using the comment syntax (`//@`). The @copy annotation is particularly useful when you want your generated code to contain text that is valid in the target pro-

gramming language but is not valid IDL. It is often used to add user comments or headers or pre-processor commands into the generated code.

```
//@copy (// Modification History)
//@copy (// -----
//@copy (// 17Jul05aaa, Created.)
//@copy
//@copy (// #include "MyTypes.h")
```

These variations allow you to use the same IDL file for multiple languages:

@copy-c	Copies code if the language is C or C++
@copy-java	Copies code if the language is Java.
@copy-ada	Copies code if the language is Ada.

For example, to add import statements to generated Java code:

```
//@copy-java (import java.util.*;)
```

The above line would be ignored if the same IDL file was used to generate non-Java code.

In C and C++ the lines are copied into all of the **foo\*.[h, c, cxx, cpp]** files generated from **foo.idl**. For Java, the lines are copied into all of the **\*.java** files that were generated from the original ".idl" file. The lines will not be copied into any additional files that are generated using the **-example** command line option.

**@copy-java-begin** copies a line of text at the beginning of all the Java files generated for a type. The annotation only applies to the first type that is immediately below in the IDL file. A similar annotation for Ada files is also available, **@copy-ada-begin**.

If you want *RTI Code Generator* to copy lines only into the files that declare the data types—**foo.h** for C and C++, **foo.java** for Java—use the **//@copy\*declaration** forms of this annotation.

Note that the first whitespace character to follow **//@copy** is considered a delimiter and will not be copied into generated files. All subsequent text found on the line, including any leading whitespaces will be copied.

<code>//@copy-declaration</code>	Copies the text into the file where the type is declared (<type>.h for C and C++, or <type>.java for Java)
<code>//@copy-c-declaration</code>	Same as <code>//@copy-declaration</code> , but for C and C++ code
<code>//@copy-java-declaration</code>	Same as <code>//@copy-declaration</code> , but for Java-only code
<code>//@copy-ada-declaration</code>	Same as <code>//@copy-declaration</code> , but for Ada-only code
<code>//@copy-java-declaration-begin</code>	Same as <code>//@copy-java-declaration</code> , but only copies the text into the file where the type is declared
<code>//@copy-ada-declaration-begin</code>	Same as <code>//@copy-java-declaration-begin</code> , but only for Ada-only code

### 17.3.9.6 The `@resolve_name` Annotation

By default, *RTI Code Generator* tries to resolve all the references to types and constants in an IDL file. For example:

```
module PackageName {
    struct Foo {
        Bar barField;
    };
};
```

The compilation of the previous IDL file will report an error like the following:

```
ERROR com.rti.ndds.nddsgen.Main Foo.idl line x:x member type 'Bar' not found
```

In most cases, this is the expected behavior. However, in some cases, you may want to skip the resolution step. For example, assume that the `Bar` type is defined in a separate IDL file and that you are running *RTI Code Generator* without an external preprocessor by using the command-line option `-ppDisable` (maybe because the preprocessor is not available in their host platform, see [17.3.8 Preprocessor Directives on page 196](#)):

#### Bar.idl

```
module PackageName {
    struct Bar {
        int32 field;
    };
};
```

#### Foo.idl

```
#include "Bar.idl"
module PackageName {
    struct Foo {
        Bar barField;
    };
};
```

In this case, compiling **Foo.idl** would generate the 'not found' error. However, `Bar` is defined in `Bar.idl`. To specify that *RTI Code Generator* should not resolve a type reference, use the `//@resolve_name` annotation and set the value to `false`. For example:

```
#include "Bar.idl"
module PackageName {
    struct Foo {
        @resolve_name(false) Bar barField;
    };
};
```

When this annotation is used, then for the field to which it applies, *RTI Code Generator* will assume that the type is an unkeyed 'structure' and it will use the type name unmodified in the generated code.

Java mapping:

```
package PackageName;
public class Foo {
    public Bar barField = Bar.create();
};
```

C++ mapping:

```
namespace PackageName {
class Foo {
    public:
        Bar barField;
};
};
```

It is up to you to include the correct header files (or if using Java, to import the correct packages) so that the compiler resolves the 'Bar' type correctly. If needed, this can be done using the copy directives (see [17.3.9.5 The @copy and Related Annotations on page 200](#)).

When applied to an aggregated type in IDL, the annotation applies to all types within the type, including the base type if defined. For example:

```
@resolve_name(false)
struct MyStructure: MyBaseStructure
{
    Foo member1;
    Bar member2;
};
```

### 17.3.9.7 The @use\_vector annotation

The @use\_vector annotation can be used in Modern C++ to indicate that a bounded sequence should be mapped to std::vector; otherwise it will be mapped to rti:core::bounded\_sequence.

For example :

```
struct MyStruct {
    @use_vector sequence<int32, 10> my_bounded_seq;
};
```

As an alternative, you can use *rtiddsgen's* **-alwaysUseStdVector** option to indicate that all bounded sequences should be mapped to std::vector. Unbounded sequences always map to std::vector.

### 17.3.9.8 The @transfer\_mode annotation

The @transfer\_mode annotation can be used to indicate how to send a sample of the annotated type. There are two possible values for this annotation: SHMEM\_REF and INBAND.

The annotation can be used only while generating code for C and C++ (Traditional and Modern) APIs. For other languages, the annotation is ignored.

@transfer\_mode(SHMEM\_REF) indicates that a sample can be sent as a shared memory reference instead of sending the serialized sample, when the *DataReader(s)* are on the same node as the *DataWriter* writing the sample. See [34.1.5 Zero Copy Transfer Over Shared Memory on page 516](#) for more information.

@transfer\_mode(INBAND) indicates that a sample is always serialized and sent inband using the underlying transports. This is the default mode when the annotation is not present.

The use of @transfer\_mode annotation without a parameter is not allowed and will generate an error during code generation.

It is sufficient to mark only the top-level types with the @transfer\_mode annotation. In this example, a sample of type **CameraImage** can be sent as a shared memory reference, even though the included type **Dimension** is not explicitly annotated:

```
struct Dimension {
    int32 height;
    int32 width;
};

@transfer_mode(SHMEM_REF)
struct CameraImage {
    int64 timestamp;
    Dimension dimension;
    octet data[8294400][4];
};
```

*RTI Code Generator* will return an error while parsing the IDL file if the following requirements are not met:

- All fixed and appendable types (described in [RTI Connex Core Libraries Extensible Types Guide](#)) annotated with @transfer\_mode(SHMEM\_REF) should be fixed-size types. A fixed-size type is a type whose wire representation always has the same size. This includes primitive members, arrays of fixed-size types, and structs containing only members of fixed-size types. In the above example, the types **CameraImage** and **Dimension** should not contain variable-length members such as strings, sequences, and optional and external members.
- Mutable types annotated with @transfer\_mode(SHMEM\_REF) can contain variable-length members when the type is also annotated with FLAT\_DATA language\_binding.

The `@transfer_mode` annotation can be applied to modules, structs, valuetypes, and unions. When applied to a module, all the types within the module inherit the language binding value specified in the module.

### 17.3.9.9 The `@language_binding` Annotation

The `@language_binding` annotation allows selecting the language binding for a type, either the plain language binding (default option when the annotation is not specified) or the RTI FlatData™ language binding.

PLAIN is the regular language binding that maps IDL types to their regular C or C++ representation as C structs or C++ classes.

FLAT\_DATA is a special language binding in which the in-memory representation is the same as the wire representation. See [34.1.4 FlatData Language Binding on page 503](#) for a detailed description.

For example:

```
@language_binding(PLAIN) // or no annotation
struct MyNormalType {
    ...
};

@language_binding(FLAT_DATA)
struct MyFlatType {
    ...
};
```

A few notes about the `@language_binding` annotation:

- The annotation can be applied to modules, structs, valuetypes, and unions. When applied to a module, all the types within the module inherit the language binding value specified in the module.
- Every member type needs to have the same language binding as the type that contains it. For example, see the IDL in [34.1.4.2.1 Selecting FlatData Language Binding on page 504](#): if **CameraImage** is marked with FLAT\_DATA language binding, **Resolution** must be marked, too.
- FLAT\_DATA is only supported in the Traditional C++ and Modern C++ language APIs. The annotation will be ignored for other languages. See [34.1.4.2.3 Languages Supported by FlatData Language Binding on page 515](#).

## 17.4 Creating User Data Types with Extensible Markup Language (XML)

You can describe user data types with Extensible Markup Language (XML) notation. *Connex* provides DTD and XSD files that describe the XML format; see `<NDDSHOME>/resource/app/app_`

`support/rtiddsgen/schema/rti_dds_topic_types.dtd` and `<NDDSHOME>/resource/app/app_support/rtiddsgen/schema/rti_dds_topic_types.xsd`, respectively. (`<NDDSHOME>` is described in [Paths Mentioned in Documentation on page 1.](#))

The XML validation performed by *RTI Code Generator* always uses the DTD definition. If the `<!DOCTYPE>` tag is not in the XML file, *RTI Code Generator* will look for the default DTD document in `<NDDSHOME>/resource/schema`. Otherwise, it will use the location specified in `<!DOCTYPE>`.

We recommend including a reference to the XSD/DTD files in the XML documents. This provides helpful features in code editors such as Visual Studio® and Eclipse™, including validation and auto-completion while you are editing the XML. We recommend including the reference to the XSD document in the XML files because it provides stricter validation and better auto-completion than the DTD document.

To include a reference to the XSD document in your XML file, use the attribute `xsi:noNamespaceSchemaLocation` in the `<types>` tag. For example:

```
<?xml version="1.0" encoding="UTF-8"?>
<types xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:noNamespaceSchemaLocation=
"<NDDSHOME>/resource/app/app_support/rtiddsgen/schema/rti_dds_topic_types.xsd">
  ...
</types>
```

To include a reference to the DTD document in your XML file, use the `<!DOCTYPE>` tag. For example:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE types SYSTEM
"<NDDSHOME>/resource/app/app_support/rtiddsgen/schema/rti_dds_topic_types.dtd">
  <types>
    ...
  </types>
```

## 17.4.1 Mapping Type System Constructs to XML

[Table 17.13 Mapping Type System Constructs to XML](#) shows how to map the type system constructs into XML. For information on the annotations in the table, see [17.3.9 Using Builtin Annotations on page 197.](#)

Table 17.13 Mapping Type System Constructs to XML

Type/Construct		Example	
IDL	XML	IDL	XML
char	char8	char char_member;	<member name="char_member" type="char8"/>
wchar	char16	wchar wchar_member;	<member name="wchar_member" type="char16"/>
octet	byte	octet octet_member;	<member name="octet_member" type="byte"/>
int8 <sup>1</sup>	int8	int8 int8_member;	<member name="int8_member" type="int8"/>
uint8 <sup>2</sup>	uint8	uint8 uint8_member;	<member name="uint8_member" type="uint8"/>
int16 or short	int16	int16 short_member;	<member name="short_member" type="int16"/>
uint16 or unsigned short	uint16	uint16 unsigned_short_member;	<member name="unsigned_short_member" type="uint16"/>
int32 or long	int32	int32 long_member;	<member name="long_member" type="int32"/>
uint32 or unsigned long	uint32	uint32 unsigned_long_member;	<member name="unsigned_long_member" type="uint32"/>
int64 or long long	int64	int64 long_long_member;	<member name="long_long_member" type="int64"/>
uint64 or unsigned long long	uint64	uint64 unsigned_long_long_ member;	<member name="unsigned_long_long_member" type="uint64"/>
float	float32	float float_member;	<member name="float_member" type="float32"/>
double	float64	double double_member;	<member name="double_member" type="float64"/>
long double	float128	long double long_double_member;	<member name="long_double_member" type="float128"/>
boolean	boolean	struct PrimitiveStruct { boolean boolean_member; };	<struct name="PrimitiveStruct"> <member name="boolean_member" type="boolean"/> </struct>

<sup>1</sup>This type is supported only at the API level. It is still considered an octet for type matching purposes.<sup>2</sup>This type is supported only at the API level. It is still considered an octet for type matching purposes.

Table 17.13 Mapping Type System Constructs to XML

Type/Construct		Example	
IDL	XML	IDL	XML
un-bounded string	string without stringMaxLength attribute or with stringMaxLength set to -1	<pre>struct PrimitiveStruct {     string string_member; };</pre>	<pre>&lt;struct name="PrimitiveStruct"&gt;   &lt;member name="string_member"     type="string"/&gt; &lt;/struct&gt;</pre> <p>or</p> <pre>&lt;struct name="PrimitiveStruct"&gt;   &lt;member name="string_member"     type="string"     stringMaxLength="-1"/&gt; &lt;/struct&gt;</pre>
bounded string	string with stringMaxLength attribute	<pre>struct PrimitiveStruct {   string&lt;20&gt; string_member; };</pre>	<pre>&lt;struct name="PrimitiveStruct"&gt;   &lt;member name="string_member"     type="string"     stringMaxLength="20"/&gt; &lt;/struct&gt;</pre>
un-bounded wstring	wstring without stringMaxLength attribute or with stringMaxLength set to -1	<pre>struct PrimitiveStruct {   wstring wstring_member; };</pre>	<pre>&lt;struct name="PrimitiveStruct"&gt;   &lt;member name="wstring_member"     type="wstring"/&gt; &lt;/struct&gt;</pre> <p>or</p> <pre>&lt;struct name="PrimitiveStruct"&gt;   &lt;member name="wstring_member"     type="wstring"     stringMaxLength="-1"/&gt; &lt;/struct&gt;</pre>
bounded wstring	wstring with stringMaxLength attribute	<pre>struct PrimitiveStruct {   wstring&lt;20&gt; wstring_   member; };</pre>	<pre>&lt;struct name="PrimitiveStruct"&gt;   &lt;member name="wstring_member"     type="wstring" stringMaxLength="20"/&gt; &lt;/struct&gt;</pre>
enum	enum tag	<pre>enum PrimitiveEnum {   ENUM1,   ENUM2,   ENUM3 };</pre>	<pre>&lt;enum name="PrimitiveEnum"&gt;   &lt;enumerator name="ENUM1"/&gt;   &lt;enumerator name="ENUM2"/&gt;   &lt;enumerator name="ENUM3"/&gt; &lt;/enum&gt;</pre>
		<pre>enum PrimitiveEnum {   ENUM1=10,   ENUM2=20,   ENUM3 } enum PrimitiveEnum {   @value (10) ENUM1,   @value (20) ENUM2,   @value (30) ENUM3 }</pre>	<pre>&lt;enum name="PrimitiveEnum"&gt;   &lt;enumerator name="ENUM1" value="10"/&gt;   &lt;enumerator name="ENUM2" value="20"/&gt;   &lt;enumerator name="ENUM3" value="30"/&gt; &lt;/enum&gt;</pre>
constant	const tag	<pre>const double PI = 3.1415;</pre>	<pre>&lt;const name="PI" type="double"   value="3.1415"/&gt;</pre>
struct	struct tag	<pre>struct PrimitiveStruct {   short short_member; };</pre>	<pre>&lt;struct name="PrimitiveStruct"&gt;   &lt;member name="short_member"     type="short"/&gt; &lt;/struct&gt;</pre>

Table 17.13 Mapping Type System Constructs to XML

Type/Construct		Example	
IDL	XML	IDL	XML
union	union tag	<pre> union PrimitiveUnion switch (long) { case 1:     short short_member; case 2: case 3:     float float_member; default:     long long_member; }; </pre>	<pre> &lt;union name="PrimitiveUnion"&gt; &lt;discriminator type="long"/&gt; &lt;case&gt;   &lt;caseDiscriminator value="1"/&gt;   &lt;member name="short_member"     type="short"/&gt; &lt;/case&gt; &lt;case&gt;   &lt;caseDiscriminator value="2"/&gt;   &lt;caseDiscriminator value="3"/&gt;   &lt;member name="float_member"     type="float"/&gt; &lt;/case&gt; &lt;case&gt;   &lt;caseDiscriminator value="default"/&gt;   &lt;member name="long_member"     type="long"/&gt; &lt;/case&gt; &lt;/union&gt; </pre>
valuetype	valuetype tag	<pre> valuetype BaseValueType {     public long long_ member; };  valuetype DerivedValueType: BaseValueType {     public long     long_member_2; }; </pre>	<pre> &lt;valuetype name="BaseValueType"&gt; &lt;member name="long_member"   type="long" visibility="public"/&gt; &lt;/valuetype&gt;  &lt;valuetype name="DerivedValueType"   baseClass="BaseValueType"&gt;   &lt;member name="long_member_2"     type="long" visibility="public"/&gt; &lt;/valuetype&gt; </pre>
typedef	typedef tag	<pre> typedef short ShortType; </pre>	<pre> &lt;typedef name="ShortType" type="short"/&gt; </pre>
		<pre> struct PrimitiveStruct {     short short_member; }; typedef PrimitiveStruct PrimitiveStructType; </pre>	<pre> &lt;struct name="PrimitiveStruct"&gt; &lt;member name="short_member"   type="short"/&gt; &lt;/struct&gt;  &lt;typedef name="PrimitiveStructType"   type="nonBasic" nonBasicTypeName="PrimitiveStruct"/&gt; </pre>
arrays	Attribute ar- rayDi- mensions	<pre> struct OneArrayStruct {     short short_array[2]; }; </pre>	<pre> &lt;struct name="OneArrayStruct"&gt;   &lt;member name="short_array"     type="short" arrayDimensions="2"/&gt; &lt;/struct&gt; </pre>
		<pre> struct TwoArrayStruct {     short short_array[1 [2]; }; </pre>	<pre> &lt;struct name="TwoArrayStruct"&gt;   &lt;member name="short_array"     type="short" arrayDimensions="1,2"/&gt; &lt;/struct&gt; </pre>
bounded sequence	Attribute se- quenceMaxLe- ngth > 0	<pre> struct SequenceStruct {     sequence&lt;short,4&gt;     short_sequence; }; </pre>	<pre> &lt;struct name="SequenceStruct"&gt;   &lt;member name="short_sequence"     type="short"     sequenceMaxLength="4"/&gt; &lt;/struct&gt; </pre>

Table 17.13 Mapping Type System Constructs to XML

Type/Construct		Example	
IDL	XML	IDL	XML
un-bounded sequence	Attribute sequenceMaxLength set to -1	<pre>struct SequenceStruct {     sequence&lt;short&gt;     short_sequence; };</pre>	<pre>&lt;struct name="SequenceStruct"&gt;   &lt;member name="short_sequence"     type="short"     sequenceMaxLength="-1"/&gt; &lt;/struct&gt;</pre>
array of sequences	Attributes sequenceMaxLength and arrayDimensions	<pre>struct ArrayOfSequencesStruct {     sequence&lt;short,4&gt;     short_sequence_array [2]; };</pre>	<pre>&lt;struct name="ArrayOfSequenceStruct"&gt;   &lt;member name= "short_sequence_array"   type="short" arrayDimensions="2"   sequenceMaxLength="4"/&gt; &lt;/struct&gt;</pre>
sequence of arrays	Must be implemented with a typedef tag	<pre>typedef short   ShortArray[2];  struct SequenceOfArraysStruct {     sequence&lt;ShortArray,2&gt;     short_array_sequence; };</pre>	<pre>&lt;typedef name="ShortArray"   type="short" dimensions="2"/&gt; &lt;struct name= "SequenceOfArrayStruct"&gt;   &lt;member name= "short_array_sequence"   type="nonBasic"   nonBasicTypeName="ShortSequence"   sequenceMaxLength="2"/&gt; &lt;/struct&gt;</pre>
sequence of sequences	Must be implemented with a typedef tag	<pre>typedef sequence&lt;short,4&gt;   ShortSequence;  struct SequenceOfSequencesStruct {     sequence&lt;ShortSequence,2&gt;     short_sequence_ sequence; };</pre>	<pre>&lt;typedef name="ShortSequence"   type="short"sequenceMaxLength="4"/&gt; &lt;struct name="SequenceofSequencesStruct"&gt; &lt;member name="short_sequence_sequence"   type="nonBasic"   nonBasicTypeName="ShortSequence"   sequenceMax-Length="2"/&gt; &lt;/struct&gt;</pre>
module	module tag	<pre>module PackageName {   struct PrimitiveStruct {     long long_member;   }; };</pre>	<pre>&lt;module name="PackageName"&gt;   &lt;struct name="PrimitiveStruct"&gt;     &lt;member name="long_member"     type="long"/&gt;   &lt;/struct&gt; &lt;/module&gt;</pre>
include	include tag (works only within the <types> tag to include types from different XML files)	<pre>#include   "PrimitiveTypes.idl"</pre>	<pre>&lt;include file="PrimitiveTypes.xml"/&gt;</pre>

Table 17.13 Mapping Type System Constructs to XML

Type/Construct		Example	
IDL	XML	IDL	XML
@key annotation <sup>1</sup>	key attribute with values true, false, 0, or 1 Default (if not present): 0	<pre>struct KeyedPrimitiveStruct {     @key short     short_member; };</pre>	<pre>&lt;struct name="KeyedPrimitiveStruct"&gt;   &lt;member name="short_member"     type="short" key="true"/&gt; &lt;/struct&gt;</pre>
@external or pointer	external attribute with values true, false, 0, or 1 Default (if not present): 0	<pre>struct PrimitiveStruct {     @external long     long_member; };</pre>	<pre>&lt;struct name="PointerStruct"&gt;   &lt;member name="long_member"     type="long"     external="true"/&gt; &lt;/struct&gt;</pre>
@optional annotation	optional attribute with values true, false, 0, or 1 Default (if not present): 0	<pre>struct Point {     long x;     long y;     @optional long z; };</pre>	<pre>&lt;struct name="Point"&gt;   &lt;member name="x" type="int32"/&gt;   &lt;member name="y" type="int32"/&gt;   &lt;member name="z" type="int32" optional="true"/&gt; &lt;/struct&gt;</pre>
@id annotation	id attribute Default (if not present): id calculated based on the @autoid value of the enclosing type and module(s)	<pre>@mutable struct Point {     @id(56) long x;     @id(57) long y;     long z; };</pre>	<pre>&lt;struct name="Point" extensibility="mutable"&gt;   &lt;member name="x" id="56" type="long"/&gt;   &lt;member name="y" id="57" type="long"/&gt;   &lt;!-- z id is 58 --&gt;   &lt;member name="y" type="long"/&gt; &lt;/struct&gt;</pre>
@hashid annotation	hashid attribute containing the string that must be hashed to compute the id Default (if not present): id calculated based on the @autoid value of the enclosing type and module(s)	<pre>@mutable struct Point {     @hashid long x;     @hashid("other_y")     long y; };</pre>	<pre>&lt;struct name="Point" extensibility="mutable"&gt;   &lt;member name="x" hashid="x" type="int32"/&gt;   &lt;member name="y" hashid="other_y" type="int32"/&gt; &lt;/struct&gt;</pre>

<sup>1</sup>For information on this and the other annotations, see [17.3.9 Using Builtin Annotations on page 197](#).

Table 17.13 Mapping Type System Constructs to XML

Type/Construct		Example	
IDL	XML	IDL	XML
@value annotation	value attribute Default (if not present): value of the previous enumerator plus 1	<pre>enum PrimitiveEnum {     @value (10) ENUM1,     @value (20) ENUM2,     ENUM3 }</pre>	<pre>&lt;enum name="PrimitiveEnum"&gt;   &lt;enumerator name="ENUM1" value="10"/&gt;   &lt;enumerator name="ENUM2" value="20"/&gt;   &lt;!-- ENUM3 id is 21 --&gt;   &lt;enumerator name="ENUM3"/&gt; &lt;/enum&gt;</pre>
@default_literal annotation	defaultLiteral attribute with values true, false, 0, or 1 Default (if not present): 0	<pre>enum MyEnum {     ENUM1,     @default_literal     ENUM2 };</pre>	<pre>&lt;enum name="MyEnum"&gt;   &lt;enumerator name="ENUM1"/&gt;   &lt;enumerator name="ENUM2" defaultLiteral="true"/&gt; &lt;/enum&gt;</pre>
@default annotation	default attribute Default (if not present in this member or its alias types): 0, the empty string, or whichever enumerator is the defaultLiteral	<pre>@default(24) typedef long MyLongTypedefWithDefault;  struct Point {     @default(42)     long x;      MyLongTypedefWithDefault     y; };</pre>	<pre>&lt;typedef name="MyLongTypedefWithDefault" type="long" default="24"/&gt; &lt;struct name="Point"&gt;   &lt;member name="x" type="long" default="42"/&gt;   &lt;member name="y" type="nonBasic" nonBasicTypeName="MyLongTypedefWithDefault"/&gt; &lt;!-- default is 24 --&gt; &lt;/struct&gt;</pre>
@min annotation	min attribute Default (if not present in this member or its alias types): the minimum possible value of the type	<pre>struct Point {     @min(-32)     long x;     long y; };</pre>	<pre>&lt;struct name="Point"&gt;   &lt;member name="x" type="long" min="-32"/&gt;   &lt;member name="y" type="long"/&gt; &lt;/struct&gt;</pre>
@max annotation	max attribute Default (if not present in this member or its alias types): the maximum possible value of the type	<pre>struct Point {     @max(31)     long x;     long y; };</pre>	<pre>&lt;struct name="Point"&gt;   &lt;member name="x" type="long" max="31"/&gt;   &lt;member name="y" type="long"/&gt; &lt;/struct&gt;</pre>
@range annotation	Not supported. Use min and max attributes instead.	<pre>struct Point {     @range(min = -32, max = 31)     long x;     long y; };</pre>	<pre>&lt;struct name="Point"&gt;   &lt;member name="x" type="long" min="32" max="31"/&gt;   &lt;member name="y" type="long"/&gt; &lt;/struct&gt;</pre>

Table 17.13 Mapping Type System Constructs to XML

Type/Construct		Example	
IDL	XML	IDL	XML
@autoid annotation	<p>autoid attribute with "hash" or "sequential" values</p> <p>Default (if not present): the @autoid value in ancestor module(s) or sequential if not specified</p>	<pre>@mutable @hashid(HASH) struct Point {     long x;     long y; };</pre>	<pre>&lt;struct name="Point" extensibility="mutable" autoid="hash"&gt;   &lt;member name="x" type="long"/&gt;   &lt;member name="y" type="long"/&gt; &lt;/struct&gt;</pre>
@nested or @top-level annotation	<p>nested attribute with values true, false, 0, or 1</p> <p>Default (if not present): 0</p>	<pre>@nested struct TopLevelPrimitiveStruct {     short short_member; }; or @top_level(false) struct TopLevelPrimitiveStruct {     short short_member; };</pre>	<pre>&lt;struct name=   "TopLevelPrimitiveStruct"   nested="true"&gt;   &lt;member name=     "short_member"     type="short"/&gt; &lt;/struct&gt;</pre>
@extensibility, @mutable, @appendable, or @final annotation	<p>extensibility attribute with values final, appendable, or mutable</p> <p>Default (if not present): appendable</p>	<pre>@mutable struct Point {     long x;     long y; };</pre>	<pre>&lt;struct name="Point" extensibility="mutable"&gt;   &lt;member name="x" type="long"/&gt;   &lt;member name="y" type="long"/&gt; &lt;/struct&gt;</pre>
@allowed_data_representation	<p>allowed_data_representation attribute with values xcdr, xcdr2, or xml</p> <p>Default (if not present): xcdr2 for FlatData language binding; the @allowed_data_representation value in ancestor module(s) or (xcdr xcdr2) for plain language binding</p>	<pre>@allowed_data_ representation(XCDR2) @mutable struct Point {     long x;     long y; };</pre>	<pre>&lt;struct name= "Point" extensibility= "mutable" allowed_data_ representation="xcdr2"&gt;   &lt;member name="x" type="int32"/&gt;   &lt;member name="y" type="int32"/&gt; &lt;/struct&gt;</pre>

Table 17.13 Mapping Type System Constructs to XML

Type/Construct		Example	
IDL	XML	IDL	XML
@use_vector	useVector attribute with values true, false, 0, or 1  Default (if not present): false unless code generated with -alwaysUseStdVector	<pre>struct Image {     @use_vector     sequence&lt;octet, 1048576&gt; pixels; };</pre>	<pre>&lt;struct name="Image"&gt;   &lt;member name="pixels" sequenceMaxLength="1048576" useVector="true" type="byte"/&gt; &lt;/struct&gt;</pre>
@language_binding annotation	languageBinding attribute with values plain or flat_data.  Default (if not present): the @language_binding value in ancestor module(s) or plain if not specified	<pre>@language_binding(FLAT_ DATA) @final struct Point {     long x;     long y; };</pre>	<pre>&lt;struct name="Point" extensibility="final" languageBinding="flat_ data"&gt;   &lt;member name="x" type="long"/&gt;   &lt;member name="y" type="long"/&gt; &lt;/struct&gt;</pre>
@transfer_mode annotation	transferMode attribute with values inband or shmem_ref.  Default (if not present): the @transfer_mode value in ancestor module(s) or inband if not specified	<pre>@transfer_mode(SHMEM_REF) struct Point {     long x;     long y; };</pre>	<pre>&lt;struct name="Point" transferMode="shmem_ref"&gt;   &lt;member name="x" type="long"/&gt;   &lt;member name="y" type="long"/&gt; &lt;/struct&gt;</pre>
@resolve_name annotation	resolveName attribute with values true, false, 0, or 1  Default (if not present): @resolve_name of the parent type or false if not specified on parent	<pre>struct UnresolvedPrimitiveStruct {     @resolve_name(false)     PrimitiveStruct primitive_member; };</pre>	<pre>&lt;struct name= "UnresolvedPrimitiveStruct"&gt;   &lt;member name="primitive_member" type="PrimitiveStruct" resolveName="false"/&gt; &lt;/struct&gt;</pre>
Other annotations	directive tag	//@copy (This text will be copied in the generated files)	<pre>&lt;directive kind="copy"&gt;   This text will be copied in the generated files &lt;/directive&gt;</pre>

## 17.5 Creating User Data Types with XML Schemas (XSD)

You can describe data types with XML schemas (XSD). The format is based on the standard IDL-to-WSDL mapping described in the OMG document "CORBA to WSDL/SOAP Interworking Specification."

Example Header for XSD:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns:dds="http://www.omg.org/dds"
  xmlns:tns="http://www.omg.org/IDL-Mapped/"
  targetNamespace="http://www.omg.org/IDL-Mapped/"
<xsd:import namespace="http://www.omg.org/dds"
  schemaLocation="rti_dds_topic_types_common.xsd"/>
...
</xsd:schema>
```

Table 17.14 Mapping Type System Constructs to XSD describes how to map IDL types to XSD. The *Connex* code generator, *rtiddsgen*, will only accept XSD files that follow this mapping.

**Table 17.14 Mapping Type System Constructs to XSD**

Type/Construct		Example	
IDL	XSD	IDL	XSD
char	dds:char <sup>1</sup>	<pre>struct PrimitiveStruct   char char_member; };</pre>	<pre>&lt;xsd:complexType name="PrimitiveStruct"&gt; &lt;xsd:sequence&gt;   &lt;xsd:element name="char_member"     minOccurs="1" maxOccurs="1"     type="dds:char"&gt;   &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>
wchar	dds:wchar <sup>2</sup>	<pre>struct PrimitiveStruct {   wchar wchar_member; };</pre>	<pre>&lt;xsd:complexType name="PrimitiveStruct"&gt; &lt;xsd:sequence&gt;   &lt;xsd:element name="wchar_member"     minOccurs="1" maxOccurs="1"     type="dds:wchar"&gt;   &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>

<sup>1</sup>All files that use the primitive types char, wchar, int8, uint8, long double, and wstring must reference `rti_dds_topic_types_common.xsd`. See [17.5.1 Primitive Types on page 233](#).

<sup>2</sup>All files that use the primitive types char, wchar, int8, uint8, long double, and wstring must reference `rti_dds_topic_types_common.xsd`. See [17.5.1 Primitive Types on page 233](#).

Table 17.14 Mapping Type System Constructs to XSD

Type/Construct		Example	
IDL	XSD	IDL	XSD
octet	xsd:unsignedByte	<pre>struct PrimitiveStruct {     octet octet_member; };</pre>	<pre>&lt;xsd:complexType name="PrimitiveStruct"&gt; &lt;xsd:sequence&gt;   &lt;xsd:element name="octet_member"     minOccurs="1" maxOccurs="1"     type="xsd:unsignedByte"&gt; &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>
int8 <sup>1</sup>	dds:int8 <sup>2</sup>	<pre>struct PrimitiveStruct {     int8 int8_member; };</pre>	<pre>&lt;xsd:complexType name="PrimitiveStruct"&gt; &lt;xsd:sequence&gt;   &lt;xsd:element name="int8_member"     minOccurs="1" maxOccurs="1"     type="dds:int8"/&gt; &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>
uint8 <sup>3</sup>	dds:uint8 <sup>4</sup>	<pre>struct PrimitiveStruct {     uint8 uint8_member; };</pre>	<pre>&lt;xsd:complexType name="PrimitiveStruct"&gt; &lt;xsd:sequence&gt;   &lt;xsd:element name="uint8_member"     minOccurs="1" maxOccurs="1"     type="dds:uint8"/&gt; &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>
int16 or short	xsd:short	<pre>struct PrimitiveStruct {     int16 short_member; };</pre>	<pre>&lt;xsd:complexType name="PrimitiveStruct"&gt; &lt;xsd:sequence&gt;   &lt;xsd:element name="short_member"     minOccurs="1" maxOccurs="1"     type="xsd:short"/&gt; &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>
uint16 or unsigned short	xsd:unsignedShort	<pre>struct PrimitiveStruct {     uint16 unsigned_short_member; };</pre>	<pre>&lt;xsd:complexType name="PrimitiveStruct"&gt; &lt;xsd:sequence&gt;   &lt;xsd:element name="     unsigned_short_member"     minOccurs="1" maxOccurs="1"     type="xsd:unsignedShort"/&gt; &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>

<sup>1</sup>This type is supported only at the API level. It is still considered an octet for type matching purposes.

<sup>2</sup>All files that use the primitive types char, wchar, int8, uint8, long double, and wstring must reference rti\_dds\_topic\_types\_common.xsd. See [17.5.1 Primitive Types on page 233](#).

<sup>3</sup>This type is supported only at the API level. It is still considered an octet for type matching purposes.

<sup>4</sup>All files that use the primitive types char, wchar, int8, uint8, long double, and wstring must reference rti\_dds\_topic\_types\_common.xsd. See [17.5.1 Primitive Types on page 233](#).

Table 17.14 Mapping Type System Constructs to XSD

Type/Construct		Example	
IDL	XSD	IDL	XSD
int32 or long	xsd:int	<pre>struct PrimitiveStruct {   int32 long_member; };</pre>	<pre>&lt;xsd:complexType name="PrimitiveStruct"&gt; &lt;xsd:sequence&gt;   &lt;xsd:element name="long_member"     minOccurs="1" maxOccurs="1"     type="xsd:int"/&gt; &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>
uint32 or unsigned long	xsd:unsignedInt	<pre>struct PrimitiveStruct {   uint32 unsigned_long_member; };</pre>	<pre>&lt;xsd:complexType name="PrimitiveStruct"&gt; &lt;xsd:sequence&gt;   &lt;xsd:element name=     "unsigned_long_member"     minOccurs="1" maxOccurs="1"     type="xsd:unsignedInt"/&gt; &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>
int64 or long long	xsd:long	<pre>struct PrimitiveStruct {   int64 long_long_member; };</pre>	<pre>&lt;xsd:complexType name="PrimitiveStruct"&gt; &lt;xsd:sequence&gt;   &lt;xsd:elementname=     "long_long_member"     minOccurs="1" maxOccurs="1"     type="xsd:long"/&gt; &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>
uint64 or unsigned long long	xsd:unsignedLong	<pre>struct PrimitiveStruct {   uint64 unsigned_long_long_   member; };</pre>	<pre>&lt;xsd:complexType name="PrimitiveStruct"&gt; &lt;xsd:sequence&gt;   &lt;xsd:element name=     "unsigned_long_long_member"     minOccurs="1" maxOccurs="1"     type="xsd:unsignedLong"/&gt; &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>
float	xsd:float	<pre>struct PrimitiveStruct {   float float_member; };</pre>	<pre>&lt;xsd:complexType name="PrimitiveStruct"&gt; &lt;xsd:sequence&gt;   &lt;xsd:element name="float_member"     minOccurs="1" maxOccurs="1"     type="xsd:float"/&gt; &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>
double	xsd:double	<pre>struct PrimitiveStruct {   double double_member; };</pre>	<pre>&lt;xsd:complexType name="PrimitiveStruct"&gt; &lt;xsd:sequence&gt;   &lt;xsd:element name="double_member"     minOccurs="1" maxOccurs="1"     type="xsd:double"/&gt; &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>
long double	dds:longDouble	<pre>struct PrimitiveStruct {   long double   long_double_member; };</pre>	<pre>&lt;xsd:complexType name="PrimitiveStruct"&gt; &lt;xsd:sequence&gt;   &lt;xsd:element name= "long_double_member"     minOccurs="1" maxOccurs="1"     type="dds:longDouble"/&gt; &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>

Table 17.14 Mapping Type System Constructs to XSD

Type/Construct		Example	
IDL	XSD	IDL	XSD
boolean	xsd:boolean	<pre>struct PrimitiveStruct {   boolean boolean_   member; };</pre>	<pre>&lt;xsd:complexType name="PrimitiveStruct"&gt; &lt;xsd:sequence&gt;   &lt;xsd:element name="boolean_member"     minOccurs="1" maxOccurs="1"     type="xsd:boolean"/&gt; &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>
un- bounded string	xsd:string	<pre>struct PrimitiveStruct {   string string_member; };</pre>	<pre>&lt;xsd:complexType name="PrimitiveStruct"&gt; &lt;xsd:sequence&gt;   &lt;xsd:element name="string_member"     minOccurs="1" maxOccurs="1"     type="xsd:string"/&gt; &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>
bounded string	xsd:string with restriction to specify max- imum length	<pre>struct PrimitiveStruct {   string&lt;20&gt;   string_member; };</pre>	<pre>&lt;xsd:complexType name=   "PrimitiveStruct_string_member_BoundedString"&gt; &lt;xsd:sequence&gt;   &lt;xsd:element name="item"     minOccurs="1" maxOccurs="1"&gt;     &lt;xsd:simpleType&gt;       &lt;xsd:restriction base="xsd:string"&gt;         &lt;xsd:maxLength           value="20" fixed="true"/&gt;       &lt;/xsd:restriction&gt;     &lt;/xsd:simpleType&gt;   &lt;/xsd:element&gt; &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre> <pre>&lt;xsd:complexType name= "PrimitiveStruct"&gt; &lt;xsd:sequence&gt;   &lt;xsd:element name="string_member"     minOccurs="1" maxOccurs="1" type=     "tns:PrimitiveStruct_string_member_BoundedString"/&gt; &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>
un- bounded wstring	dds:wstring <sup>1</sup>	<pre>struct PrimitiveStruct {   wstring   wstring_member; };</pre>	<pre>&lt;xsd:complexType name="PrimitiveStruct"&gt; &lt;xsd:sequence&gt;   &lt;xsd:element name="wstring_member"     minOccurs="1" maxOccurs="1"     type="dds:wstring"/&gt; &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>

<sup>1</sup>All files that use the primitive types char, wchar, int8, uint8, long double and wstring must reference rti\_dds\_topic\_types\_common.xsd. See [17.5.1 Primitive Types on page 233](#)

Table 17.14 Mapping Type System Constructs to XSD

Type/Construct		Example	
IDL	XSD	IDL	XSD
bounded wstring	xsd:wstring with restriction to specify maximum length	<pre>struct PrimitiveStruct {     wstring&lt;20&gt;     wstring_member; };</pre>	<pre>&lt;xsd:complexType name= "PrimitiveStruct_wstring_member_BoundedString" &lt;xsd:sequence&gt;   &lt;xsd:element name="item"     minOccurs="1" maxOccurs="1"&gt;     &lt;xsd:simpleType&gt;       &lt;xsd:restriction base="dds:wstring"&gt;         &lt;xsd:maxLength value="20"           fixed="true"/&gt;       &lt;/xsd:restriction&gt;     &lt;/xsd:simpleType&gt;   &lt;/xsd:element&gt; &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;  &lt;xsd:complexType name= "PrimitiveStruct"&gt; &lt;xsd:sequence&gt;   &lt;xsd:element name="wstring_member" minOccurs="1" maxOccurs="1" type= "tns:PrimitiveStruct_wstring_member_BoundedString"/&gt; &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>
enum	xsd:simpleType with enumeration	<pre>enum PrimitiveEnum {     ENUM1,     ENUM2,     ENUM3 };</pre>	<pre>&lt;xsd:simpleType name="PrimitiveEnum"&gt;   &lt;xsd:restriction base="xsd:string"&gt;     &lt;xsd:enumeration value="ENUM1"/&gt;     &lt;xsd:enumeration value="ENUM2"/&gt;     &lt;xsd:enumeration value="ENUM3"/&gt;   &lt;/xsd:restriction&gt; &lt;/xsd:simpleType&gt;  &lt;xsd:simpleType name="PrimitiveEnum"&gt;   &lt;xsd:restriction base="xsd:string"&gt;     &lt;xsd:enumeration value="ENUM1"&gt;       &lt;xsd:annotation&gt;         &lt;xsd:appinfo&gt;           &lt;ordinal&gt;10&lt;/ordinal&gt;         &lt;/xsd:appinfo&gt;       &lt;/xsd:annotation&gt;     &lt;/xsd:enumeration&gt;     &lt;xsd:enumeration value="ENUM2"&gt;       &lt;xsd:annotation&gt;         &lt;xsd:appinfo&gt;           &lt;ordinal&gt;20&lt;/ordinal&gt;         &lt;/xsd:appinfo&gt;       &lt;/xsd:annotation&gt;     &lt;/xsd:enumeration&gt;     &lt;xsd:enumeration value="ENUM3"&gt;       &lt;xsd:annotation&gt;         &lt;xsd:appinfo&gt;           &lt;ordinal&gt;30&lt;/ordinal&gt;         &lt;/xsd:appinfo&gt;       &lt;/xsd:annotation&gt;     &lt;/xsd:enumeration&gt;   &lt;/xsd:restriction&gt; &lt;/xsd:simpleType&gt;</pre>

Table 17.14 Mapping Type System Constructs to XSD

Type/Construct		Example	
IDL	XSD	IDL	XSD
		<pre>enum PrimitiveEnum {     ENUM1 = 10,     ENUM2 = 20,     ENUM3 = 30 };</pre>	<pre>&lt;xsd:simpleType name="PrimitiveEnum"&gt;   &lt;xsd:restriction base="xsd:string"&gt;     &lt;xsd:enumeration value="ENUM1"&gt;       &lt;xsd:annotation&gt;         &lt;xsd:appinfo&gt;           &lt;ordinal&gt;10&lt;/ordinal&gt;         &lt;/xsd:appinfo&gt;       &lt;/xsd:annotation&gt;     &lt;/xsd:enumeration&gt;     &lt;xsd:enumeration value="ENUM2"&gt;       &lt;xsd:annotation&gt;         &lt;xsd:appinfo&gt;           &lt;ordinal&gt;20&lt;/ordinal&gt;         &lt;/xsd:appinfo&gt;       &lt;/xsd:annotation&gt;     &lt;/xsd:enumeration&gt;     &lt;xsd:enumeration value="ENUM3"&gt;       &lt;xsd:annotation&gt;         &lt;xsd:appinfo&gt;           &lt;ordinal&gt;30&lt;/ordinal&gt;         &lt;/xsd:appinfo&gt;       &lt;/xsd:annotation&gt;     &lt;/xsd:enumeration&gt;   &lt;/xsd:restriction&gt; &lt;/xsd:simpleType&gt;</pre>
constant	IDL constants are mapped by substituting their value directly in the generated file		
struct	xsd-complexType with xsd:sequence	<pre>struct PrimitiveStruct {   short short_member; };</pre>	<pre>&lt;xsd:complexType name="PrimitiveStruct"&gt;   &lt;xsd:sequence&gt;     &lt;xsd:element name="short_member"       minOccurs="1" maxOccurs="1"       type="xsd:short"/&gt;   &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>

Table 17.14 Mapping Type System Constructs to XSD

Type/Construct		Example	
IDL	XSD	IDL	XSD
union	xsd:-complexType with xsd:choice	<pre> union PrimitiveUnion switch (long) {   case 1:     short short_member;   default:     long long_member; }; </pre>	<pre> &lt;xsd:complexType name="PrimitiveUnion"&gt;   &lt;xsd:sequence&gt;     &lt;xsd:element name="discriminator"       type="xsd:int"/&gt;     &lt;xsd:choice&gt;       &lt;!-- case 1 --&gt;<sup>1</sup>       &lt;xsd:element name="short_member"         minOccurs="0" maxOccurs="1"         type="xsd:short"&gt;         &lt;xsd:annotation&gt;           &lt;xsd:appinfo&gt;             &lt;case&gt;1&lt;/case&gt;           &lt;/xsd:appinfo&gt;         &lt;/xsd:annotation&gt;       &lt;/xsd:element&gt;       &lt;!-- case default --&gt;       &lt;xsd:element name="long_member"         minOccurs="0" maxOccurs="1"         type="xsd:int"&gt;         &lt;xsd:annotation&gt;           &lt;xsd:appinfo&gt;             &lt;case&gt;default&lt;/case&gt;           &lt;/xsd:appinfo&gt;         &lt;/xsd:annotation&gt;       &lt;/xsd:element&gt;     &lt;/xsd:choice&gt;   &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt; </pre>

<sup>1</sup>The discriminant values can be described using comments (as specified by the standard) or xsd:annotation tags. We recommend using annotations because comments may be removed by XSD/XML parsers.

Table 17.14 Mapping Type System Constructs to XSD

Type/Construct		Example	
IDL	XSD	IDL	XSD
value-type	xsd:complexType with @valuetype annotation	<pre> valuetype BaseValueType {     public long long_     member; };  valuetype DerivedValueType: BaseValueType {     public long long_     member2;     public long long_     member3; }; </pre>	<pre> &lt;xsd:complexType name="BaseValueType"&gt;   &lt;xsd:sequence&gt;     &lt;xsd:element name="long_member"       maxOccurs="1" minOccurs="1"       type="xs:int"/&gt;     &lt;!-- @visibility public --&gt;   &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;  &lt;!-- @valuetype true --&gt; &lt;xsd:complexType name="DerivedValueType"&gt;   &lt;xsd:complexContent&gt;     &lt;xsd:extension base="BaseValueType"&gt;       &lt;xsd:sequence&gt;         &lt;xsd:element name="long_member2"           maxOccurs="1" minOccurs="1"           type="xs:int"/&gt;         &lt;!-- @visibility public --&gt;         &lt;xsd:element name="long_member3"           maxOccurs="1" minOccurs="1"           type="xs:int"/&gt;         &lt;!-- @visibility public --&gt;       &lt;/xsd:sequence&gt;     &lt;/xsd:extension&gt;   &lt;/xsd:complexContent&gt; &lt;/xsd:complexType&gt; &lt;!-- @valuetype true --&gt; </pre>
typedef	Type definitions are mapped to XML schema type restrictions	<pre> typedef short ShortType; struct PrimitiveStruct {     short short_member; };  typedef PrimitiveType =     PrimitiveStructType; </pre>	<pre> &lt;xsd:simpleType name="ShortType"&gt;   &lt;xsd:restriction base="xsd:short"/&gt; &lt;/xsd:simpleType&gt;  &lt;!-- Struct definition --&gt; &lt;xsd:complexType name="PrimitiveStruct"&gt;   &lt;xsd:sequence&gt;     &lt;xsd:element name="short_member"       minOccurs="1" maxOccurs="1"       type="xsd:short"/&gt;   &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;  &lt;!-- Typedef definition --&gt; &lt;xsd:complexType   name="PrimitiveTypeStructType"&gt;   &lt;xsd:complexContent&gt;     &lt;xsd:restriction base="PrimitiveStruct"&gt;       &lt;xsd:sequence&gt;         &lt;xsd:element name="short_member"           minOccurs="1" maxOccurs="1"           type="xsd:short"/&gt;       &lt;/xsd:sequence&gt;     &lt;/xsd:restriction&gt;   &lt;/xsd:complexContent&gt; &lt;/xsd:complexType&gt; </pre>

Table 17.14 Mapping Type System Constructs to XSD

Type/Construct		Example	
IDL	XSD	IDL	XSD
arrays	<p>n xsd:-complexType with sequence containing one element with min &amp; max occurs</p> <p>There is one xsd:-complexType per array dimension</p>	<pre>struct OneArrayStruct {     short short_array[2]; };</pre>	<pre>&lt;!-- Array type --&gt; &lt;xsd:complexType name=     "OneArrayStruct_short_array_ArrayOfShort"&gt;   &lt;xsd:sequence&gt;     &lt;xsd:element name="item" minOccurs="2"       maxOccurs="2" type="xsd:short"&gt;     &lt;/xsd:element&gt;   &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;  &lt;!-- Struct w unidimensional array member --&gt; &lt;xsd:complexType name="OneArrayStruct"&gt;   &lt;xsd:sequence&gt;     &lt;xsd:element name="short_array"       minOccurs="1" maxOccurs="1"       type=         "OneArrayStruct_short_array_ArrayOfShort"/&gt;   &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>
arrays (cont'd)	<p>n xsd:-complexType with sequence containing one element with min &amp; max occurs</p> <p>There is one xsd:-complexType per array dimension</p>	<pre>struct TwoArrayStruct {     short short_array[2]     [1]; };</pre>	<pre>&lt;!--Second dimension array type --&gt; &lt;xsd:complexType name=     "TwoArrayStruct_short_array_ArrayOfShort"&gt;   &lt;xsd:sequence&gt;     &lt;xsd:element name="item"       minOccurs="2" maxOccurs="2"       type="xsd:short"&gt;     &lt;/xsd:element&gt;   &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;  &lt;!-- First dimension array type --&gt; &lt;xsd:complexType name=     "TwoArrayStruct_short_array_ArrayOfArrayOfShort"&gt;   &lt;xsd:sequence&gt;     &lt;xsd:element name="item"       minOccurs="1" maxOccurs="1"       type=         "TwoArrayStruct_short_array_ArrayOfShort"&gt;     &lt;/xsd:element&gt;   &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;  &lt;!--Struct containing a bidimensional array member --&gt; &lt;xsd:complexType name="TwoArrayStruct"&gt;   &lt;xsd:sequence&gt;     &lt;xsd:element name="short_array"       minOccurs="1" maxOccurs="1"       type=         "TwoArrayStruct_short_array_ArrayOfArrayOfShort"/&gt;   &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>

Table 17.14 Mapping Type System Constructs to XSD

Type/Construct		Example	
IDL	XSD	IDL	XSD
bounded sequence	xsd:-complexType with sequence containing one element with min & max occurs	<pre>struct SequenceStruct {   sequence&lt;short,4&gt;   short_sequence; };</pre>	<pre>&lt;!-- Sequence type --&gt; &lt;xsd:complexType name= "SequenceStruct_short_sequence_SequenceOfShort"&gt;   &lt;xsd:sequence&gt;     &lt;xsd:element name="item" minOccurs="0" maxOccurs="4" type="xsd:short"&gt;   &lt;/xsd:element&gt; &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;  &lt;!-- Struct containing a bounded sequence member --&gt; &lt;xsd:complexType name="SequenceStruct"&gt;   &lt;xsd:sequence&gt;     &lt;xsd:element name="short_sequence" minOccurs="1" maxOccurs="1" type= "SequenceStruct_short_sequence_SequenceOfShort"/&gt;   &lt;/xsd:sequence&gt; &lt;/xsd:complexType&gt;</pre>

other annotations	<pre>&lt;!-- &lt;@directive kind&gt; &lt;value&gt; --&gt;</pre>	<pre>//@copy This text will be   copied in the generated files</pre>	<pre>&lt;!--@copy This text will be copied in the generated files --&gt;</pre>

## 17.5.1 Primitive Types

The primitive types `char`, `wchar`, `long double`, and `wstring` are not supported natively in XSD. *Connex* provides definitions for these types in the file `<NDDSHOME>/resource/app/app_support/rtiddsgen/schema`. All files that use the primitive types `char`, `wchar`, `long double` and `wstring` must reference `rti_dds_topic_types_common.xsd`. For example:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns:dds="http://www.omg.org/dds">
<xsd:import namespace="http://www.omg.org/dds"
  schemaLocation="rti_dds_topic_types_common.xsd"/>
```

```

<xsd:complexType name="Foo">
  <xsd:sequence>
    <xsd:element name="myChar" minOccurs="1"
      maxOccurs="1" type="dds:char"/>
  </xsd:sequence>
</xsd:complexType>
</xsd:schema>

```

## 17.6 Using RTI Code Generator (rtiddsgen)

*RTI Code Generator* creates the code needed to define and register a user-data type with *Connex*. Using this tool is optional if:

- You are using dynamic types (see [17.8 Interacting Dynamically with User Data Types on page 236](#))
- You are using one of the built-in types (see [17.2 Built-in Data Types on page 121](#))

See the [RTI Code Generator User's Manual](#) for more information.

## 17.7 Using Generated Types without Connex (Standalone)

You can use the generated type-specific source and header files without linking the *Connex* libraries or even including the *Connex* header files. That is, the files generated by *RTI Code Generator* for your data types can be used standalone.

The directory `<NDDSHOME>/resource/app/app_support/rtiddsgen/standalone` contains the required helper files:

- include: header and templates files for C and C++.
- src: source files for C and C++.
- class: Java jar file.

### 17.7.1 Using Standalone Types in C

The generated files that can be used standalone are:

- `<idl file name>.c`: Types source file
- `<idl file name>.h`: Types header file

The type plug-in code (`<idl file>Plugin.[c,h]`) and type-support code (`<idl file>Support.[c,h]`) cannot be used standalone.

**To use the generated types in a standalone manner:**

1. Include the directory `<NDDSHOME>/resource/app/app_support/rtiddsgen/standalone/include` in the list of directories to be searched for header files.
2. Add the source files, `ndds_standalone_type.c` and `<idl file name>.c`, to your project.
3. Include the file `<idl file name>.h` in the source files that will use the generated types in a standalone manner.
4. Compile the project using the following two preprocessor definitions:
  - `NDDS_STANDALONE_TYPE`
  - The definition for your platform (`RTI_VXWORKS`, `RTI_QNX`, `RTI_WIN32`, `RTI_INTY`, `RTI_LYNX` or `RTI_UNIX`)

**17.7.2 Using Standalone Types in C++**

(This section applies to the Traditional C++ API only)

The generated files that can be used standalone are:

- `<idl file name>.cxx`: Types source file
- `<idl file name>.h`: Types header file

The type-plugin code (`<idl file>Plugin.[cxx,h]`) and type-support code (`<idl file>Support.[cxx,h]`) cannot be used standalone.

**To use the generated types in a standalone manner:**

1. Include the directory `<NDDSHOME>/resource/app/app_support/rtiddsgen/standalone/include` in the list of directories to be searched for header files.
2. Add the source files, `ndds_standalone_type.cxx` and `<idl file name>.cxx`, to your project.
3. Include the file `<idl file name>.h` in the source files that will use the *RTI Code Generator* types in a standalone manner.
4. Compile the project using the following two preprocessor definitions:
  - `NDDS_STANDALONE_TYPE`
  - The definition for your platform (such as `RTI_VXWORKS`, `RTI_QNX`, `RTI_WIN32`, `RTI_INTY`, `RTI_LYNX` or `RTI_UNIX`)

**17.7.3 Standalone Types in Java**

The generated files that can be used standalone are:

- `<idl type>.java`
- `<idl type>Seq.java`

The type code (`<idl file>TypeCode.java`), type-support code (`<idl type>TypeSupport.java`), *DataReader* code (`<idl file>DataReader.java`) and *DataWriter* code (`<idl file>DataWriter.java`) cannot be used standalone.

**To use the generated types in a standalone manner:**

1. Include the file `ndds_standalone_type.jar` in the classpath of your project.
2. Compile the project using the standalone types files (`<idl type>.java` and `<idl type>Seq.java`).

## 17.8 Interacting Dynamically with User Data Types

### 17.8.1 Type Schemas and TypeCode Objects

Type schemas—the names and definitions of a type and its fields—are represented by TypeCode objects, described in [17.1.3 Introduction to TypeCode on page 120](#).

### 17.8.2 Defining New Types

This section does not apply when using the separate add-on product, *Ada Language Support*, which does not support Dynamic Types.

Locally, your application can access the type code for a generated type "Foo" by calling the `FooTypeSupport::get_typecode()` (Traditional C++ Notation) operation in the code for the type generated by *RTI Code Generator*. But you can also create TypeCodes at run time without any code generation.

Creating a TypeCode is parallel to the way you would define the type statically: you define the type itself with some name, then you add members to it, each with its own name and type.

For example, consider the following statically defined type. It might be in C, C++, or IDL; the syntax is largely the same.

```

struct MyType {
    int32 my_integer;
    float my_float;
    bool my_bool;
    @key string<128> my_string;
};

```

**This is how you would define the same type at run time in the Traditional C++ API:**

```

DDS_ExceptionCode_t ex = DDS_NO_EXCEPTION_CODE;
DDS_StructMemberSeq structMembers; // ignore for now
DDS_TypeCodeFactory* factory =
    DDS_TypeCodeFactory::get_instance();
DDS_TypeCode* structTc = factory->create_struct_tc(
    "MyType", structMembers, ex);
// If structTc is NULL, check 'ex' for more information.
structTc->add_member(
    "my_integer", DDS_TYPECODE_MEMBER_ID_INVALID,
    factory->get_primitive_tc(DDS_TK_LONG),
    DDS_TYPECODE_NONKEY_REQUIRED_MEMBER, ex);
structTc->add_member(
    "my_float", DDS_TYPECODE_MEMBER_ID_INVALID,
    factory->get_primitive_tc(DDS_TK_FLOAT),
    DDS_TYPECODE_NONKEY_REQUIRED_MEMBER, ex);
structTc->add_member(
    "my_bool", DDS_TYPECODE_MEMBER_ID_INVALID,
    factory->get_primitive_tc(DDS_TK_BOOLEAN),
    DDS_TYPECODE_NONKEY_REQUIRED_MEMBER, ex);
structTc->add_member(
    "my_string", DDS_TYPECODE_MEMBER_ID_INVALID,
    factory->create_string_tc(128),
    DDS_TYPECODE_KEY_MEMBER, ex);

```

More detailed documentation for the methods and constants you see above, including example code, can be found in the [API Reference HTML documentation](#), which is available for all supported programming languages.

If, as in the example above, you know all of the fields that will exist in the type at the time of its construction, you can use the **StructMemberSeq** to simplify the code:

```

DDS_StructMemberSeq structMembers;
structMembers.ensure_length(4, 4);
DDS_TypeCodeFactory* factory = DDS_TypeCodeFactory::get_instance();
structMembers[0].name = DDS_String_dup("my_integer");
structMembers[0].type = factory->get_primitive_tc(DDS_TK_LONG);
structMembers[1].name = DDS_String_dup("my_float");
structMembers[1].type = factory->get_primitive_tc(DDS_TK_FLOAT);
structMembers[2].name = DDS_String_dup("my_bool");
structMembers[2].type = factory->get_primitive_tc(DDS_TK_BOOLEAN);
structMembers[3].name = DDS_String_dup("my_string");
structMembers[3].type = factory->create_string_tc(128);
structMembers[3].is_key = DDS_BOOLEAN_TRUE;
DDS_ExceptionCode_t ex = DDS_NO_EXCEPTION_CODE;
DDS_TypeCode* structTc =

```

```
factory->create_struct_tc(
    "MyType", structMembers, ex);
```

After you have defined the `TypeCode`, you will register it with a *DomainParticipant* using a logical name (note: this step is not required in the Modern C++ API). You will use this logical name later when you create a *Topic*.

```
DDSDynamicDataTypeSupport* type_support =
    new DDSDynamicDataTypeSupport(structTc,
        DDS_DYNAMIC_DATA_TYPE_PROPERTY_DEFAULT);
DDS_ReturnCode_t retcode =
    type_support->register_type(participant,
        "My Logical Type Name");
```

For code examples for the Modern C++ API, please refer to the API Reference HTML documentation: [Modules](#), [Programming How-To's](#), [DynamicType](#) and [DynamicData Use Cases](#).

Now that you have created a type, you will need to know how to interact with objects of that type. See [17.8.3 Sending Only a Few Fields below](#) for more information.

### 17.8.3 Sending Only a Few Fields

In some cases, your data model may contain a large number of potential fields, but it may not be desirable or appropriate to include a value for every one of them with every DDS data sample.

- **It may use too much bandwidth.** You may have a very large data structure, parts of which are updated very frequently. Rather than resending the entire data structure with every change, you may wish to send only those fields that have changed and rely on the recipients to reassemble the complete state themselves.
- **It may not make sense.** Some fields may only have meaning in the presence of other fields. For example, you may have an event stream in which certain fields are only relevant for certain kinds of events.

To support these and similar cases, *Connex* supports mutable types and optional members (see the [RTI Connex Core Libraries Extensible Types Guide](#)).

### 17.8.4 Sending Type Information on the Network

In addition to being used locally, the type information of a *Topic* is published automatically during discovery as part of the builtin topics for publications and subscriptions. See [17.1.3.1 Sending Type Information on the Network on page 121](#).

#### 17.8.4.1 Type Codes for Built-in Types

The type codes associated with the built-in types are generated from the following IDL type definitions:

```

module DDS {
  /* String */
  struct String {
    string<max_size> value;
  };
  /* KeyedString */
  struct KeyedString {
    string<max_size> key; //@key
    string<max_size> value;
  };
  /* Octets */
  struct Octets {
    sequence<octet, max_size> value;
  };
  /* KeyedOctets */
  struct KeyedOctets {
    string<max_size> key; //@key
    sequence<octet, max_size> value;
  };
};
};

```

The maximum size (**max\_size**) of the strings and sequences that will be included in the type code definitions can be configured on a per-*DomainParticipant*-basis by using the properties in [Table 17.15 Properties for Allocating Size of Built-in Types, per DomainParticipant](#).

**Table 17.15 Properties for Allocating Size of Built-in Types, per DomainParticipant**

Built-in Type	Property	Description
String	dds.builtin_type.string.max_size	Maximum size of the strings published by the <i>DataWriters</i> and received by the <i>DataReaders</i> belonging to a <i>DomainParticipant</i> (includes the NULL-terminated character). Default: 1024
KeyedString	dds.builtin_type.keyed_string.max_key_size	Maximum size of the keys used by the <i>DataWriters</i> and <i>DataReaders</i> belonging to a <i>DomainParticipant</i> (includes the NULL-terminated character). Default: 1024
	dds.builtin_type.keyed_string.max_size	Maximum size of the strings published by the <i>DataWriters</i> and received by the <i>DataReaders</i> belonging to a <i>DomainParticipant</i> using the built-in type (includes the NULL-terminated character). Default: 1024
Octets	dds.builtin_type.octets.max_size	Maximum size of the octet sequences published by the <i>DataWriters</i> and <i>DataReaders</i> belonging to a <i>DomainParticipant</i> . Default: 2048

**Table 17.15 Properties for Allocating Size of Built-in Types, per DomainParticipant**

Built-in Type	Property	Description
Keyed-Octets	dds.builtin_type.keyed_octets.max_key_size	Maximum size of the key published by the <i>DataWriter</i> and received by the <i>DataReaders</i> belonging to the <i>DomainParticipant</i> (includes the NULL-terminated character). Default: 1024.
	dds.builtin_type.keyed_octets.max_size	Maximum size of the octet sequences published by the <i>DataWriters</i> and <i>DataReaders</i> belonging to a <i>DomainParticipant</i> . Default: 2048

## 17.9 Working with DDS Data Samples

You should now understand how to define and work with data types, whether you're using the simple data types built into the middleware (see [17.2 Built-in Data Types on page 121](#)), dynamically defined types (see [17.2.7 Managing Memory for Built-in Types on page 147](#)), or code generated from IDL or XML files (see [17.3 Creating User Data Types with IDL on page 153](#) and [17.4 Creating User Data Types with Extensible Markup Language \(XML\) on page 205](#)).

Now that you have chosen one or more data types to work with, this section will help you understand how to create and manipulate objects of those types.

### 17.9.1 Objects of Concrete Types

If you use one of the built-in types or decide to generate custom types from an IDL or XML file, your *Connex* data type is like any other data type in your application: a class or structure with fields, methods, and other members that you interact with directly.

#### In C

You create and delete your own objects from factories, just as you create *Connex* objects from factories. In the case of user data types, the factory is a singleton object called the type support. Objects allocated from these factories are deeply allocated and fully initialized.

```
/* In the generated header file: */
struct MyData {
    char* myString;
};
/* In your code: */
MyData* sample = MyDataTypeSupport_create_data();
char* str = sample->myString; /*empty, non-NULL string*/
/* ... */
MyDataTypeSupport_delete_data(sample);
```

**In Traditional C++:**

Without the **-constructor** option, you create and delete objects using the TypeSupport factories.

```
MyData* sample = MyDataTypeSupport::create_data();
char* str = sample->myString; // empty, non-NULL string
// ...
MyDataTypeSupport::delete_data(sample);
```

With the **-constructor** option, generated types have a default constructor, a copy constructor, and a destructor. In this case the TypeSupport data creation methods are not available.

```
// In the header file
class MyType
{
    MyType();
    MyType(const MyType& that);
    ~MyType();
    MyType& operator=(const MyType& that);
};
```

**In Modern C++:**

Generated types have value-type semantics and provide a default constructor, a constructor with parameters to initialize all the members, a copy constructor and assignment operator, a move constructor and move-assignment operator, a destructor, equality operators, a swap function and an overloaded operator<<. Data members are accessed using getters and setters.

```
// In the generated header file
class MyData {
public:
    MyData();
    explicit MyData(const std::string& myString);

    // Note: the implicit destructor, copy and
    // move constructors, and assignment operators
    // are available
    std::string& myString() OMG_NOEXCEPT;
    const std::string& myString() const OMG_NOEXCEPT;
    void myString(const std::string& value);

    bool operator == (const MyData& other_) const;
    bool operator != (const MyData& other_) const;
private:
    // ...
};

void swap(MyData& a, MyData& b) OMG_NOEXCEPT
    std::ostream& operator <<
        (std::ostream& o, const MyData& sample);
```

```
// In your code:
MyData sample("Hello");
sample.myString("Bye");
```

**In C#:**

You can use a no-argument constructor to allocate objects. Those objects will be deallocated by the garbage collector as appropriate.

```
// In your code, if you are using C#:
MyData sample = new MyData();
string str = sample.myString; // empty, non-null string
```

**In Java:**

You can use a no-argument constructor to allocate objects. Those objects will be deallocated by the garbage collector as appropriate.

```
// In the generated code:
public class MyData {
    public String myString = "";
}
// In your code:
MyData sample = new MyData();
String str = sample->myString;
// empty, non-null string
```

## 17.9.2 Objects of Dynamically Defined Types

If you are working with a data type that was discovered or defined at run time, you will use the reflective API provided by the `DynamicData` class to get and set the fields of your object.

Consider the following type definition:

```
struct MyData {
    int32 myInteger;
};
```

As with a statically defined type, you will create objects from a `TypeSupport` factory. How to create or otherwise obtain a `TypeCode`, and how to subsequently create from it a `DynamicDataTypeSupport`, is described in [17.8.2 Defining New Types on page 236](#). In the Modern C++ API you will use the `DynamicData` constructor, which receives a `DynamicType`.

For more information about the `DynamicData` and `DynamicDataTypeSupport` classes, consult the API Reference HTML documentation, which is available for all supported programming languages (select **Modules, RTI Connex API Reference, Topic Module, Dynamic Data**).

**In C:**

```

DDS_DynamicDataTypeSupport* support = ...;
DDS_DynamicData* sample = DDS_DynamicDataTypeSupport_create_data(support);
DDS_Long theInteger = 0;
DDS_ReturnCode_t success = DDS_DynamicData_set_long(sample,
    "myInteger", DDS_DYNAMIC_DATA_MEMBER_ID_UNSPECIFIED, 5);
/* Error handling omitted. */
success = DDS_DynamicData_get_long(    sample, &theInteger,
    "myInteger", DDS_DYNAMIC_DATA_MEMBER_ID_UNSPECIFIED);
/* Error handling omitted. "theInteger" now contains the value 5
   if no error occurred.
   */
*/

```

**In Traditional C++:**

```

DDS_DynamicDataTypeSupport* support = ...;
DDS_DynamicData* sample = support->create_data();
DDS_ReturnCode_t success = sample->set_long("myInteger",
    DDS_DYNAMIC_DATA_MEMBER_ID_UNSPECIFIED, 5);
// Error handling omitted.
DDS_Long theInteger = 0;
success = sample->get_long(    &theInteger, "myInteger",
    DDS_DYNAMIC_DATA_MEMBER_ID_UNSPECIFIED);
// Error handling omitted.
// "theInteger" now contains the value 5 if no error occurred.

```

**In Modern C++:**

```

using namespace dds::core::xtypes;
StructType type(
    "MyData", {
        Member("myInteger", primitive_type<int32_t>())
    }
);
DynamicData sample(type);
sample.value("myInteger", 5);
int32_t the_int = sample.value<int32_t>("myInteger");
// "the_int" now contains the value 5 if no exception was thrown

```

**In C#:**

```

using Rti.Types.Dynamic;
...
var factory = DynamicTypeFactory.Instance;
var myType = factory.BuildStruct()
    .WithName("MyData")
    .AddMember(new StructMember("myInteger", factory.GetPrimitiveType<int>()))
    .Create();
var sample = new DynamicData(myType);
sample.SetValue("myInteger", 5);
var theInt = sample.GetValue<int>("myInteger");
// "theInt" now contains the value 5 if no exception was thrown

```

**In Java:**

```
import com.rti.dds.dynamicdata.*;
DynamicDataSupport support = ...;
DynamicData sample = (DynamicData) support.create_data();
sample.set_int("myInteger", DynamicData.MEMBER_ID_UNSPECIFIED, 5);
int theInteger = sample.get_int("myInteger",
    DynamicData.MEMBER_ID_UNSPECIFIED);
/* Exception handling omitted.
 * "theInteger" now contains the value 5 if no error occurred.
 */
```

The Modern C++ API provides convenience functions to convert among DynamicData samples and typed samples (such as MyData, from the previous example). For example:

```
#include "MyData.hpp"
// ...
MyData typed_sample(44);
DynamicData dynamic_sample = rti::core::xtypes::convert(typed_sample);
assert (dynamic_sample.value<int32_t>("myInteger") == 44);
dynamic_sample.value("myInteger", 33);
typed_sample = rti::core::xtypes::convert<MyData>(dynamic_sample);
assert (typed_sample.myInteger() == 33);
```

**17.9.3 Serializing and Deserializing Data Samples**

There are two TypePlugin operations to serialize a sample into a buffer and deserialize a sample from a buffer. The sample serialization/deserialization uses CDR representation.

The feature is supported in the following languages: C, Modern and Traditional C++, Java, and .NET.

**C:**

```
#include "FooSupport.h"
FooTypeSupport_serialize_data_to_cdr_buffer(...)
FooTypeSupport_deserialize_data_from_cdr_buffer(...)
```

**Traditional C++**

```
#include "FooSupport.h"
FooTypeSupport::serialize_data_to_cdr_buffer(...)
FooTypeSupport::deserialize_data_from_cdr_buffer(...)
```

**Modern C++**

```
#include "Foo.hpp"
dds::topic::topic_type_support<Foo>::to_cdr_buffer(...)
dds::topic::topic_type_support<Foo>::from_cdr_buffer(...)
```

**Java:**

```
FooTypeSupport.get_instance().serialize_to_cdr_buffer(...)
FooTypeSupport.get_instance().deserialize_from_cdr_buffer(...)
```

**C#:**

```
ISerializer<MyType> serializer = MyTypeSupport.Instance.CreateSerializer();
var sampleBuffer = serializer.Serialize(sample);
MyType deserializedSample = serializer.Deserialize(sampleBuffer);
```

## 17.9.4 Accessing the Discriminator Value in a Union

A union type can only hold a single member. The **member\_id** for this member is equal to the discriminator value. To get the value of the discriminator, use the operation **get\_member\_info\_by\_index()** on the `DynamicData` using an index value of 0. This operation fills in a `DynamicDataMemberInfo` structure, which includes a **member\_id** field that is the value of the discriminator.

Once you know the discriminator value, you can use the proper version of **get\_<type>()** (such as **get\_long()**) to access the member value.

For example:

```
DynamicDataMemberInfo memberInfo = new DynamicDataMemberInfo();
myDynamicData.get_member_info_by_index(memberInfo, 0);
int discriminatorValue = memberInfo.member_id;
int myMemberValue = myDynamicData.get_long(null, discriminatorValue);
```

The Modern C++ API provides the method **discriminator\_value()** to achieve the same result:

```
int32_t my_member_value = my_dynamic_data.value<int32_t>(
    my_dynamic_data.discriminator_value());
```

## 17.10 Data Sample Serialization Limits

*Connex* does not support data types with samples whose maximum serialized size is bigger than 2,147,482,623 bytes. If the maximum serialized size is bigger than this, the behavior is undefined.

For types containing unbounded sequences or strings where the code is generated using the **-unboundedSupport** command-line option in *RTI Code Generator*, the maximum serialized size is implicitly set to 2,147,482,623.

# Chapter 18 Working with Topics

For a *DataWriter* and *DataReader* to communicate, they need to use the same *Topic*. A *Topic* includes a name and an association with a user data type that has been registered with *Connex*. Topic names are how different parts of the communication system find each other. *Topics* are named streams of data of the same data type. *DataWriters* publish DDS samples into the stream; *DataReaders* subscribe to data from the stream. More than *one* *Topic* can use the same user data type, but each *Topic* needs a unique name.

*Topics*, *DataWriters*, and *DataReaders* relate to each other as follows:

- Multiple *Topics* (each with a unique name) can use the same user data type.
- Applications may have multiple *DataWriters* for each *Topic*.
- Applications may have multiple *DataReaders* for each *Topic*.
- *DataWriters* and *DataReaders* must be associated with the same *Topic* in order for them to be connected.
- *Topics* are created and deleted by a *DomainParticipant*, and as such, are owned by that *DomainParticipant*. When two applications (*DomainParticipants*) want to use the same *Topic*, they must both create the *Topic* (even if the applications are on the same node).

*Connex* uses ‘Builtin Topics’ to discover and keep track of remote entities, such as new participants in the DDS domain. Builtin Topics are discussed in [Accessing Discovery Information through Built-In Topics \(Chapter 28 on page 359\)](#).

## 18.1 Topics

Before you can create a *Topic*, you need a user data type (see [Data Types and DDS Data Samples \(Chapter 17 on page 110\)](#)) and a *DomainParticipant* ([DomainParticipants \(16.3 on page 81\)](#)). The user data type must be registered with the *DomainParticipant* (see [17.2.8 Type Codes for Built-in Types on page 152](#)).

Once you have created a *Topic*, what do you do with it? Topics are primarily used as parameters in other *Entities*' operations. For instance, a *Topic* is required when a *Publisher* or *Subscriber* creates a *DataWriter* or *DataReader*, respectively. *Topics* do have a few operations of their own, as listed in [Table 18.1 Topic Operations](#). For details on using these operations, see the reference section or the API Reference HTML documentation.

Figure 18.1: Topic Module

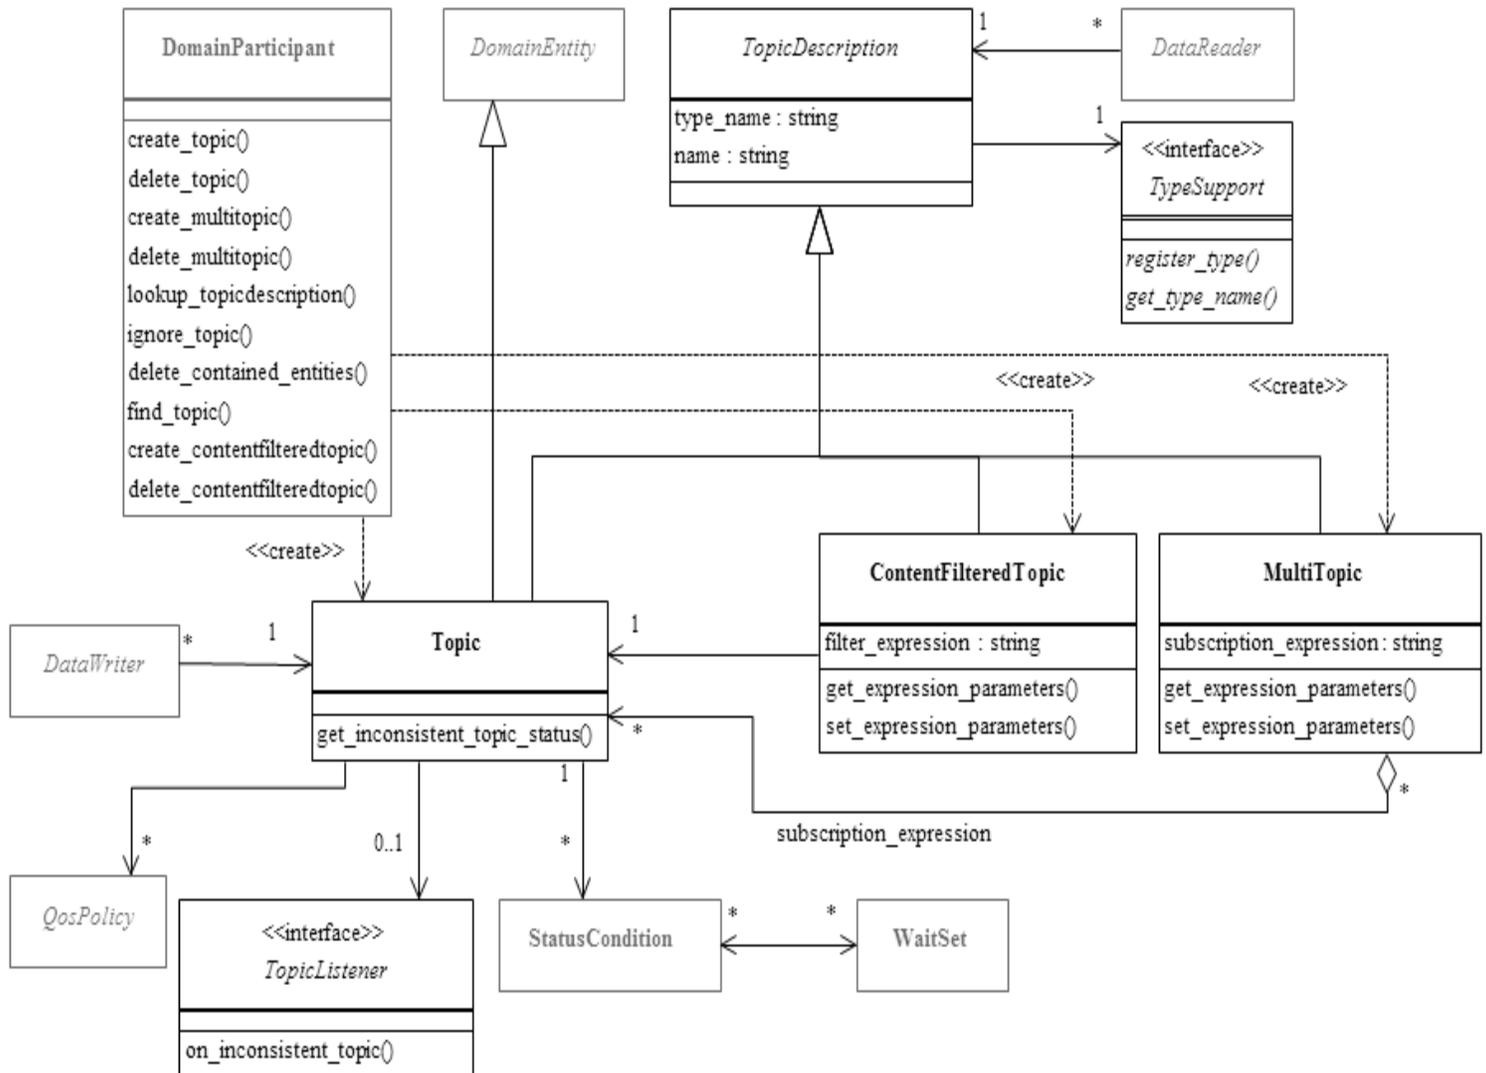

Table 18.1 Topic Operations

Purpose	Operation	Description	Reference
Configuring the Topic	enable	Enables the <i>Topic</i> .	<a href="#">15.2 Enabling DDS Entities on page 35</a>
	get_qos	Gets the <i>Topic</i> 's current QoSPolicy settings. This is most often used in preparation for calling <code>set_qos()</code> .	<a href="#">18.1.3 Setting Topic QoS Policies on page 250</a>
	set_qos	Sets the <i>Topic</i> 's QoS. You can use this operation to change the values for the <i>Topic</i> 's QoS Policies. Note, however, that not all QoS Policies can be changed after the <i>Topic</i> has been created.	
	equals	Compares two <i>Topic</i> 's QoS structures for equality.	<a href="#">18.1.3.2 Comparing QoS Values on page 253</a>
	set_qos_with_profile	Sets the <i>Topic</i> 's QoS based on a specified QoS profile.	
	get_listener	Gets the currently installed Listener.	<a href="#">18.1.5 Setting Up TopicListeners on page 255</a>
	set_listener	Sets the <i>Topic</i> 's Listener. If you create the <i>Topic</i> without a Listener, you can use this operation to add one later. Setting the listener to NULL will remove the listener from the <i>Topic</i> .	
	narrow	A type-safe way to cast a pointer. This takes a <code>DDSTopicDescription</code> pointer and 'narrows' it to a <code>DDSTopic</code> pointer.	<a href="#">31.7 Using a Type-Specific DataWriter (FooDataWriter) on page 409</a>
Checking Status	get_inconsistent_topic_status	Allows an application to retrieve a <i>Topic</i> 's <code>INCONSISTENT_TOPIC_STATUS</code> status.	<a href="#">18.2.1 INCONSISTENT_TOPIC Status on page 256</a>
	get_status_changes	Gets a list of statuses that have changed since the last time the application read the status or the listeners were called.	<a href="#">15.4 Getting Status and Status Changes on page 38</a>
Navigating Relationships	get_name	Gets the <code>topic_name</code> string used to create the <i>Topic</i> .	<a href="#">18.1.1 Creating Topics below</a>
	get_type_name	Gets the <code>type_name</code> used to create the <i>Topic</i> .	
	get_participant	Gets the <code>DomainParticipant</code> to which this <i>Topic</i> belongs.	<a href="#">18.1.6.1 Finding a Topic's DomainParticipant on page 255</a>

## 18.1.1 Creating Topics

*Topics* are created using the `DomainParticipant`'s `create_topic()` or `create_topic_with_profile()` operation.

A QoS profile is way to use QoS settings from an XML file or string. With this approach, you can change QoS settings without recompiling the application. For details, see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

```
DDSTopic * create_topic (
    const char *topic_name,
    const char *type_name,
    const DDS_TopicQos &qos,
```

```

    DDSListener *listener,
    DDS_StatusMask mask)
DDSListener * create_topic_with_profile (
    const char *topic_name,
    const char *type_name,
    const char *library_name,
    const char *profile_name,
    DDSListener *listener,
    DDS_StatusMask mask)

```

Where:

<b>topic_name</b>	Name for the new <i>Topic</i> , must not exceed 255 characters.
<b>type_name</b>	Name for the user data type, must not exceed 255 characters. It must be the same name that was used to register the DDS type, and the DDS type must be registered with the same <i>DomainParticipant</i> used to create this <i>Topic</i> . See <a href="#">17.6 Using RTI Code Generator (rtiddsgen) on page 234</a> .
<b>qos</b>	<p>If you want to use the default QoS settings (described in the API Reference HTML documentation), use <code>DDS_TOPIC_QOS_DEFAULT</code> for this parameter (see <a href="#">Figure 18.2: Creating a Topic with Default QoS Policies on the next page</a>). If you want to customize any of the QoS Policies, supply a QoS structure (see <a href="#">18.1.3 Setting Topic QoS Policies on the next page</a>).</p> <p>If you use <code>DDS_TOPIC_QOS_DEFAULT</code>, it is <i>not</i> safe to create the topic while another thread may be simultaneously calling the <i>DomainParticipant's</i> <code>set_default_topic_qos()</code> operation.</p>
<b>listener</b>	<i>Listeners</i> are callback routines. <i>Connex</i> uses them to notify your application of specific events (status changes) that may occur with respect to the <i>Topic</i> . The <i>listener</i> parameter may be set to NULL if you do not want to install a <i>Listener</i> . If you use NULL, the <i>Listener</i> of the <i>DomainParticipant</i> to which the <i>Topic</i> belongs will be used instead (if it is set). For more information on <i>TopicListeners</i> , see <a href="#">18.1.5 Setting Up TopicListeners on page 255</a> .
<b>mask</b>	This bit-mask indicates which status changes will cause the <i>Listener</i> to be invoked. The bits in the mask that are set must have corresponding callbacks implemented in the <i>Listener</i> . If you use NULL for the <i>Listener</i> , use <code>DDS_STATUS_MASK_NONE</code> for this parameter. If the <i>Listener</i> implements all callbacks, use <code>DDS_STATUS_MASK_ALL</code> . For information on statuses, see <a href="#">15.8 Listeners on page 46</a> .
<b>library_name</b>	A QoS Library is a named set of QoS profiles. See <a href="#">50.2 QoS Profiles on page 906</a> . If NULL is used for <b>library_name</b> , the <i>DomainParticipant's</i> default library is assumed.
<b>profile_name</b>	A QoS profile groups a set of related QoS, usually one per entity. See <a href="#">50.2 QoS Profiles on page 906</a> . If NULL is used for <b>profile_name</b> , the <i>DomainParticipant's</i> default profile is assumed and <b>library_name</b> is ignored.

It is not safe to create a topic while another thread is calling `lookup_topicdescription()` for that same topic (see [16.3.8 Looking up Topic Descriptions on page 102](#)).

Figure 18.2: Creating a Topic with Default QoS Policies

```

const char *type_name = NULL;
// register the DDS type
type_name = FooTypeSupport::get_type_name();
retcode = FooTypeSupport::register_type(
    participant, type_name);
if (retcode != DDS_RETCODE_OK) {
    // handle error
}
// create the topic
DDSTopic* topic = participant->create_topic(
    "Example Foo", type_name,
    DDS_TOPIC_QOS_DEFAULT,
    NULL, DDS_STATUS_MASK_NONE);
if (topic == NULL) {
    // process error here
};

```

For more examples, see [18.1.3.1 Configuring QoS Settings when the Topic is Created on page 252](#).

## 18.1.2 Deleting Topics

To delete a Topic, use the DomainParticipant's `delete_topic()` operation:

```
DDS_ReturnCode_t delete_topic (DDSTopic * topic)
```

Note, however, that you cannot delete a Topic if there are any existing *DataReaders* or *DataWriters* (belonging to the same *DomainParticipant*) that are still using it. All *DataReaders* and *DataWriters* associated with the *Topic* must be deleted first.

**Note:** In the Modern C++ API, *Entities* are automatically destroyed.

## 18.1.3 Setting Topic QoS Policies

A *Topic's* QoS Policies control its behavior, or more specifically, the behavior of the *DataWriters* and *DataReaders* of the *Topic*. You can think of the policies as the 'properties' for the *Topic*. The `DDS_TopicQos` structure has the following format:

```

DDS_TopicQos struct {
    DDS_TopicDataQosPolicy      topic_data;
    DDS_DurabilityQosPolicy     durability;
    DDS_DurabilityServiceQosPolicy  durability_service;
    DDS_DeadlineQosPolicy       deadline;
    DDS_LatencyBudgetQosPolicy   latency_budget;
    DDS_LivelinessQosPolicy     liveliness;
    DDS_ReliabilityQosPolicy     reliability;
    DDS_DestinationOrderQosPolicy destination_order;
    DDS_HistoryQosPolicy        history;
    DDS_ResourceLimitsQosPolicy  resource_limits;
    DDS_TransportPriorityQosPolicy transport_priority;
    DDS_LifespanQosPolicy       lifespan;
    DDS_OwnershipQosPolicy      ownership;
}

```

```
    DDS_DataRepresentationQoSPolicy    representation
} DDS_TopicQoS;
```

[Table 18.2 Topic QoS Policies](#) summarizes the meaning of each policy (arranged alphabetically). For information on *why* you would want to change a particular QoS Policy, see the section noted in the **Reference** column. For defaults and valid ranges, please refer to the API Reference HTML documentation for each policy.

Table 18.2 Topic QoS Policies

QoS Policy	Description
DataRepresentation	Specifies which versions of the Extended Common Data Representation (CDR) are offered and requested. See <a href="#">47.3 DATA_REPRESENTATION QoS Policy on page 780</a> . During <code>Publisher_copy_from_topic_qos</code> , only the first <code>DataRepresentationId_t</code> element is copied to the <code>DataWriterQos</code> . The whole sequence is copied to the <code>DataReaderQos</code> during <code>Subscriber_copy_from_topic_qos</code> .
Deadline	For a <i>DataReader</i> , specifies the maximum expected elapsed time between arriving DDS data samples. For a <i>DataWriter</i> , specifies a commitment to publish DDS samples with no greater elapsed time between them. See <a href="#">47.7 DEADLINE QoS Policy on page 804</a> .
DestinationOrder	Controls how <i>Connex</i> t will deal with data sent by multiple <i>DataWriters</i> for the same topic. Can be set to "by reception timestamp" or to "by source timestamp". See <a href="#">47.8 DESTINATION_ORDER QoS Policy on page 806</a> .
Durability	Specifies whether or not <i>Connex</i> t will store and deliver data that were previously published to new <i>DataReaders</i> . See <a href="#">47.9 DURABILITY QoS Policy on page 809</a> .
DurabilityService	Various settings to configure the external Persistence Service used by <i>Connex</i> t for <i>DataWriters</i> with a Durability QoS setting of Persistent Durability. See <a href="#">47.10 DURABILITY SERVICE QoS Policy on page 814</a> .
History	Specifies how much data must be stored by <i>Connex</i> t for the <i>DataWriter</i> or <i>DataReader</i> . This QoS Policy affects the <a href="#">47.21 RELIABILITY QoS Policy on page 845</a> as well as the <a href="#">47.9 DURABILITY QoS Policy on page 809</a> . See <a href="#">47.12 HISTORY QoS Policy on page 818</a> .
LatencyBudget	Suggestion to <i>Connex</i> t on how much time is allowed to deliver data. See <a href="#">47.13 LATENCYBUDGET QoS Policy on page 823</a> .
Lifespan	Specifies how long <i>Connex</i> t should consider data sent by an user application to be valid. See <a href="#">47.14 LIFESPAN QoS Policy on page 824</a> .
Liveliness	Specifies and configures the mechanism that allows <i>DataReaders</i> to detect when <i>DataWriters</i> become disconnected or "dead." See <a href="#">47.15 LIVELINESS QoS Policy on page 825</a> .
Ownership	Along with Ownership Strength, specifies if <i>DataReaders</i> for a topic can receive data from multiple <i>DataWriters</i> at the same time. See <a href="#">47.17 OWNERSHIP QoS Policy on page 833</a> .
Reliability	Specifies whether or not <i>Connex</i> t will deliver data reliably. See <a href="#">47.21 RELIABILITY QoS Policy on page 845</a> .
ResourceLimits	Controls the amount of physical memory allocated for entities, if dynamic allocations are allowed, and how they occur. Also controls memory usage among different instance values for keyed topics. See <a href="#">47.22 RESOURCE_LIMITS QoS Policy on page 850</a> .
TopicData	Along with Group Data QoS Policy and User Data QoS Policy, used to attach a buffer of bytes to <i>Connex</i> t's discovery meta-data. See <a href="#">45.1 TOPIC_DATA QoS Policy on page 737</a> .
TransportPriority	Set by a <i>DataWriter</i> to tell <i>Connex</i> t that the data being sent is a different "priority" than other data. See <a href="#">47.26 TRANSPORT_PRIORITY QoS Policy on page 856</a> .

### 18.1.3.1 Configuring QoS Settings when the Topic is Created

As described in [18.1.1 Creating Topics on page 248](#), there are different ways to create a Topic, depending on how you want to specify its QoS (with or without a QoS profile).

In [Figure 18.2: Creating a Topic with Default QoS Policies on page 250](#), we saw an example of how to create a Topic with default QoS Policies by using the special constant, `DDS_TOPIC_QOS_DEFAULT`, which indicates that the default QoS values for a *Topic* should be used. The default Topic QoS values are configured in the `DomainParticipant`; you can change them with the `DomainParticipant`'s `set_`

**default\_topic\_qos()** or **set\_default\_topic\_qos\_with\_profile()** operations (see [16.3.7.5 Getting and Setting Default QoS for Child Entities on page 101](#)).

To create a Topic with non-default QoS values, without using a QoS profile, use the *DomainParticipant's* **get\_default\_topic\_qos()** operation to initialize a `DDS_TopicQos` structure. Then change the policies from their default values before passing the QoS structure to **create\_topic()**.

You can also create a *Topic* and specify its QoS settings via a QoS profile. To do so, call **create\_topic\_with\_profile()**.

If you want to use a QoS profile, but then make some changes to the QoS before creating the Topic, call **get\_topic\_qos\_from\_profile()**, modify the QoS and use the modified QoS when calling **create\_topic()**.

### 18.1.3.2 Comparing QoS Values

The **equals()** operation compares two *Topic's* `DDS_TopicQos` structures for equality. It takes two parameters for the two *Topics'* QoS structures to be compared, then returns `TRUE` if they are equal (all values are the same) or `FALSE` if they are not equal.

### 18.1.3.3 Changing QoS Settings After the Topic Has Been Created

There are two ways to change an existing Topic's QoS after it has been created—again depending on whether or not you are using a QoS Profile.

To change QoS programmatically (that is, without using a QoS Profile), see the example code in [Figure 18.3: Changing the QoS of an Existing Topic \(without a QoS Profile\) below](#). It retrieves the current values by calling the Topic's **get\_qos()** operation. Then it modifies the value and calls **set\_qos()** to apply the new value. Note, however, that some QoS Policies cannot be changed after the Topic has been enabled—this restriction is noted in the descriptions of the individual QoS Policies.

You can also change a *Topic's* (and all other Entities') QoS by using a QoS Profile. For an example, see [Figure 18.4: Changing the QoS of an Existing Topic with a QoS Profile on the next page](#). For more information, see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

For the C API, use `DDS_TopicQos_INITIALIZER` or `DDS_TopicQos_initialize()`. See [42.2 Special QoS Policy Handling Considerations for C on page 688](#).

**Figure 18.3: Changing the QoS of an Existing Topic (without a QoS Profile)**

```
DDS_TopicQos topic_qos;
// Get current QoS. topic points to an existing DDS_Topic.
if (topic->get_qos(topic_qos) != DDS_RETCODE_OK) {
    // handle error
}
// Next, make changes.
// New ownership kind will be Exclusive
topic_qos.ownership.kind = DDS_EXCLUSIVE_OWNERSHIP_QOS;
```

```
// Set the new QoS
if (topic->set_qos(topic_qos) != DDS_RETCODE_OK ) {
    // handle error
}
```

Figure 18.4: Changing the QoS of an Existing Topic with a QoS Profile

```
retcode = topic->set_qos_with_profile(
    "FooProfileLibrary", "FooProfile");
if (retcode != DDS_RETCODE_OK) {
    // handle error
}
```

## 18.1.4 Copying QoS From a Topic to a DataWriter or DataReader

Only the `TOPIC_DATA` QoSPolicy strictly applies to *Topics*—it is described in this section, while the others are described in the sections noted [Table 18.2 Topic QoS Policies](#). The rest of the QoS Policies for a *Topic* can also be set on the corresponding *DataWriters* and/or *DataReaders*. Actually, the values that *Connex* uses for those policies are taken directly from those set on the *DataWriters* and *DataReaders*. The values for those policies are stored only for reference in the `DDS_TopicQos` structure.

Because many QoS Policies affect the behavior of matching *DataWriters* and *DataReaders*, the `DDS_TopicQos` structure is provided as a convenient way to set the values for those policies in a single place in the application. Otherwise, you would have to modify the individual QoS Policies within separate *DataWriter* and *DataReader* QoS structures. And because some QoS Policies are compared between *DataReaders* and *DataWriters*, you will need to make certain that the individual values that you set are compatible (see [42.1 QoS Requested vs. Offered Compatibility—the RxO Property on page 687](#)).

The use of the `DDS_TopicQos` structure to set the values of any QoS Policy except `TOPIC_DATA`—which only applies to *Topics*—is really a way to share a single set of values with the associated *DataWriters* and *DataReaders*, as well as to avoid creating those entities with inconsistent QoS Policies.

To cause a *DataWriter* to use its *Topic*'s QoS settings, either:

- Pass `DDS_DATAWRITER_QOS_USE_TOPIC_QOS` to `create_datawriter()`, or
- Call the *Publisher*'s `copy_from_topic_qos()` operation

To cause a *DataReader* to use its *Topic*'s QoS settings, either:

- Pass `DDS_DATAREADER_QOS_USE_TOPIC_QOS` to `create_datareader()`, or
- Call the *Subscriber*'s `copy_from_topic_qos()` operation

Please refer to the API Reference HTML documentation for the *Publisher*'s `create_datawriter()` and *Subscriber*'s `create_datareader()` methods for more information about using values from the *Topic* QoS Policies when creating *DataWriters* and *DataReaders*.

## 18.1.5 Setting Up TopicListeners

When you create a *Topic*, you have the option of giving it a *Listener*. A *TopicListener* includes just one callback routine, `on_inconsistent_topic()`. If you create a *TopicListener* (either as part of the *Topic* creation call, or later with the `set_listener()` operation), *Connex* will invoke the *TopicListener*'s `on_inconsistent_topic()` method whenever it detects that another application has created a *Topic* with same name but associated with a different user data type. For more information, see [18.2.1 INCONSISTENT\\_TOPIC Status on the next page](#).

**Note:** Some operations cannot be used within a listener callback, see [15.8.8.1 Restricted Operations in Listener Callbacks on page 57](#).

If a *Topic*'s Listener has not been set and *Connex* detects an inconsistent *Topic*, the *DomainParticipantListener* (if it exists) will be notified instead (see [16.3.6 Setting Up DomainParticipantListeners on page 94](#)). So you only need to set up a **TopicListener** if you need to perform specific actions when there is an error on that particular *Topic*. In most cases, you can set the *TopicListener* to NULL and process inconsistent-topic errors in the *DomainParticipantListener* instead.

## 18.1.6 Navigating Relationships Among Entities

### 18.1.6.1 Finding a Topic's DomainParticipant

To retrieve a handle to the *Topic*'s *DomainParticipant*, use the `get_participant()` operation:

```
DDSDomainParticipant* DDSTopicDescription::get_participant()
```

Notice that this method belongs to the **DDSTopicDescription** class, which is the base class for **DDSTopic**.

### 18.1.6.2 Retrieving a Topic's Name or DDS Type Name

If you want to retrieve the *topic\_name* or *type\_name* used in the `create_topic()` operation, use these methods:

```
const char* DDSTopicDescription::get_type_name();
const char* DDSTopicDescription::get_name();
```

Notice that these methods belong to the **DDSTopicDescription** class, which is the base class for **DDSTopic**.

## 18.2 Status Indicator for Topics

There is only one communication status defined for a *Topic*, `ON_INCONSISTENT_TOPIC`. You can use the `get_inconsistent_topic_status()` operation to access the current value of the status or use a *TopicListener* to catch the change in the status as it occurs. See [15.8 Listeners on page 46](#) for a general discussion on Listeners and Statuses.

## 18.2.1 INCONSISTENT\_TOPIC Status

In order for a *DataReader* and a *DataWriter* with the same *Topic* to communicate, their DDS types must be consistent according to the *DataReader's* type-consistency enforcement policy value, defined in its [48.6 TYPE\\_CONSISTENCY\\_ENFORCEMENT QosPolicy on page 894](#)). This status indicates that another *DomainParticipant* has created a *Topic* using the same name as the local *Topic*, but with an inconsistent DDS type.

The status is a structure of type **DDS\_InconsistentTopicStatus**, see [Table 18.3 DDS\\_InconsistentTopicStatus Structure](#). The **total\_count** keeps track of the total number of (*DataReader*, *DataWriter*) pairs with topic names that match the *Topic* to which this status is attached, but whose DDS types are inconsistent. The *TopicListener's* **on\_inconsistent\_topic()** operation is invoked when this status changes (an inconsistent topic is found). You can also retrieve the current value by calling the *Topic's* **get\_inconsistent\_topic\_status()** operation.

The value of **total\_count\_change** reflects the number of inconsistent topics that were found since the last time **get\_inconsistent\_topic\_status()** was called by user code or **on\_inconsistent\_topic()** was invoked by *Connex*.

**Table 18.3 DDS\_InconsistentTopicStatus Structure**

Type	Field Name	Description
DDS_Long	total_count	Total cumulative count of ( <i>DataReader</i> , <i>DataWriter</i> ) pairs whose topic names match the <i>Topic</i> to which this status is attached, but whose DDS types are inconsistent.
DDS_Long	total_count_change	The change in total_count since the last time this status was read.

## 18.3 ContentFilteredTopics

A *ContentFilteredTopic* is a *Topic* with filtering properties. It makes it possible to subscribe to topics and at the same time specify that you are only interested in a subset of the *Topic's* data.

For example, suppose you have a *Topic* that contains a temperature reading for a boiler, but you are only interested in temperatures outside the normal operating range. A *ContentFilteredTopic* can be used to limit the number of DDS data samples a *DataReader* has to process and may also reduce the amount of data sent over the network.

See [Chapter 35 Filtering Data on page 546](#) for complete information.

# Chapter 19 Working with Instances

Instances are a way for an application to represent unique objects within a *Topic*, by specifying one or more key fields that form a unique identifier for the instance. Examples include identifying unique commercial flights within a “Flight Status” *Topic* or a unique sensor measuring the temperature in a “Temperature” *Topic*.

Modeling data using instances can provide several benefits to a system, including:

- An application can represent dynamic behavior of objects that come and go in a system, such as aircraft that may fly within range of a radar system and then fly out of range. See [19.1 Instance States on the next page](#) for more details.
- Many QoS policies are applied per instance. For example, the [47.12 HISTORY QoS Policy on page 818](#) **depth** is applied per instance. This allows an application to specify: “Keep the last N samples for every instance this *DataReader* receives.” See [19.2.1 QoS Policies that are Applied per Instance on page 264](#) for more examples.
- An application can use *DataReader* methods such as **read\_instance()** and **take\_instance()** to process all the samples for an instance at once.
- *ContentFilteredTopics* are more efficient when filtering instances. Using *ContentFilteredTopics* in combination with instances is a great way to allow applications to take advantage of writer-side filtering to only subscribe to logical subsets of a *Topic* by specifying the instances that they are interested in.

Instances are defined by key fields that make up a unique identifier of the object being represented. Key fields are similar to primary keys in a database—each unique combination of key field values represents a unique instance. Key fields are specified using the `@key` directive, as shown in [Chapter 8 DDS Samples, Instances, and Keys on page 17](#).

Table 19.1 Example Keys and Instances

Instance (object represented in data)	Key (field/s uniquely identifying object)	Data type	Sample (update to object)
Commercial flight being tracked	Airline name and flight number, such as: Airline: "United Airlines" Flight number: 901	@key string airline @key int16 flight_num float lat float long	<b>UA, 901</b> , 37.7749, 122.4194 <b>UA, 901</b> , 37.7748, 122.4195
Sensor that is sending data, such as an individual temperature sensor	Unique identifier of that sensor, such as: "Floor-08-South"	@key string sensor_id int32 temperature	<b>Floor-08-South</b> , 78 <b>Floor-08-South</b> , 79
Car being monitored	Vehicle identification number (VIN) of the car	@key string VIN float lat float long	<b>JH4DA9370MS016526</b> , 37.7749, 122.4194 <b>JH4DA9370MS016526</b> , 37.7748, 122.4195

See the following sections:

- [19.1 Instance States below](#)
- [19.2 QoS Configuration and Instances on page 264](#)
- [19.3 Instance Metadata Memory Management on page 268](#)

See also more details on instances from the *DataWriter* and *DataReader* perspectives:

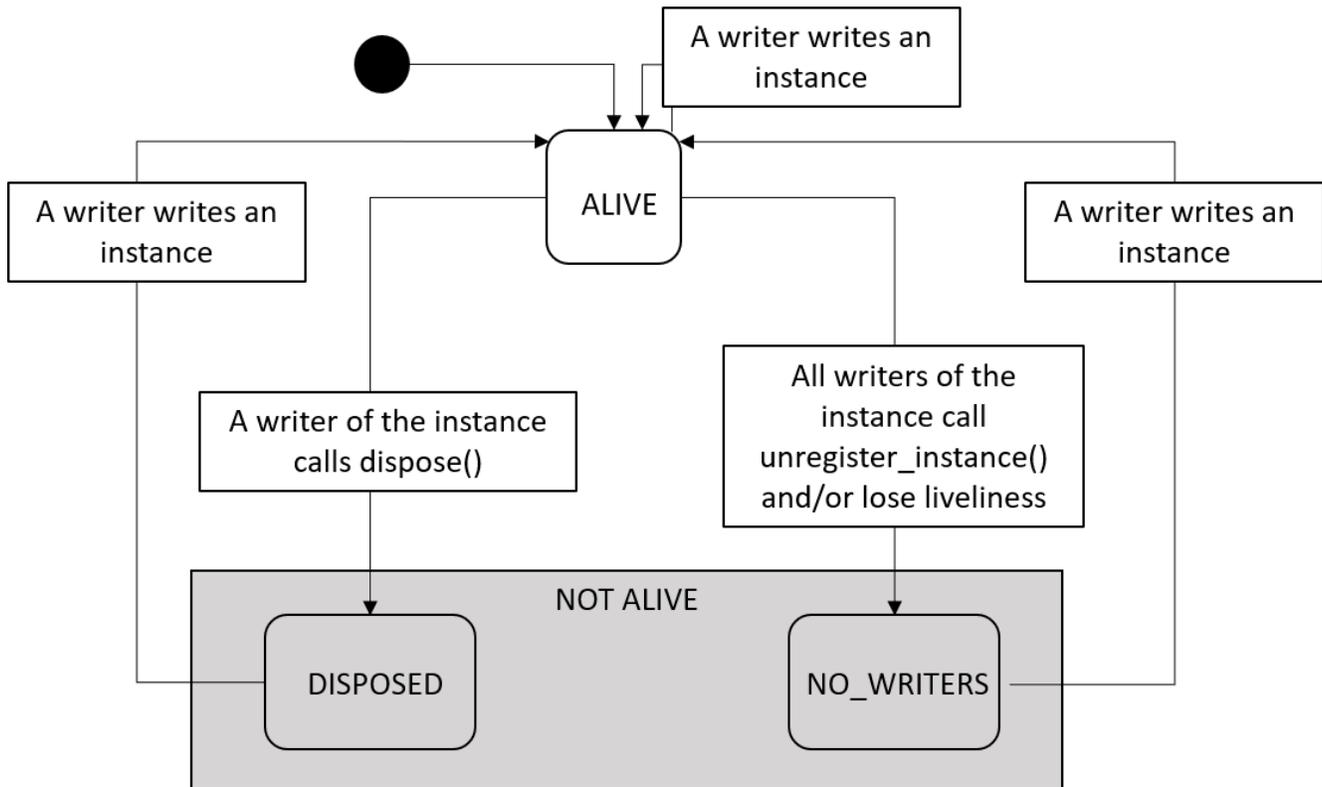

- For the *DataWriter*: [31.14 Managing Instances \(Working with Keyed Data Types\) on page 425](#)
- For the *DataReader*: [40.8 Accessing and Managing Instances \(Working with Keyed Data Types\) on page 643](#)

## 19.1 Instance States

Instances can be in one of three states:

- **ALIVE**: An existing *DataWriter* has written a sample of the instance.
- **NOT\_ALIVE\_DISPOSED**: A *DataWriter* that has written the instance has called **dispose()** on the instance. (See [31.14.3 Disposing Instances on page 428](#) for further clarification when using EXCLUSIVE Ownership.)
- **NOT\_ALIVE\_NO\_WRITERS**: All *DataWriters* that have written the instances have gone away (more on that later), or called **unregister\_instance()** to unregister themselves from the instance.

Figure 19.1: Overview of Instance States and Transitions

### 19.1.1 ALIVE Details

The **ALIVE** instance state indicates that there is a *DataWriter* actively updating that instance, and no *DataWriter* has declared the instance to be “disposed” (see below).

An instance becomes **ALIVE** when a *DataWriter* writes a sample of that instance. This is true regardless of the previous state of the instance. For example, if an instance is **NOT\_ALIVE\_DISPOSED**, it becomes alive again when a *DataWriter* writes the instance. The only way for the instance to transition to becoming **ALIVE** is for a *DataWriter* to write a sample of that instance.

**Instances and OWNERSHIP QoS:** If the *DataWriters*’ QoS is set to **OWNERSHIP = EXCLUSIVE**, the *DataWriter* with the highest **OWNERSHIP\_STRENGTH** that has written the instance is the owner of the instance, unless it unregisters the instance, loses liveliness, or is deleted. If the instance has been disposed, only the *DataWriter* that owns that instance can make it transition to the **ALIVE** state by writing that instance. See [47.17 OWNERSHIP QoS Policy on page 833](#).

### 19.1.2 NOT\_ALIVE\_DISPOSED Details

The **NOT\_ALIVE\_DISPOSED** instance state indicates that a *DataWriter* has explicitly changed the state of an instance to **NOT\_ALIVE\_DISPOSED** by calling the **dispose()** method on the instance. The meaning of an instance becoming **NOT\_ALIVE\_DISPOSED** is part of the design of a system.

When a *DataWriter* calls **dispose()** on an instance, a dispose message is propagated from the *DataWriter* to its matching *DataReaders* to tell those *DataReaders* that the instance's state is changed to **NOT\_ALIVE\_DISPOSED**.

Many systems use the **NOT\_ALIVE\_DISPOSED** instance state to indicate that the object that the instance represents has gone away. For example, in a “FlightData” topic, a system may use the **NOT\_ALIVE\_DISPOSED** instance state to indicate that the aircraft tracked by a radar system has flown out of range or has landed.

One common misconception is that the memory belonging to a disposed instance is immediately freed when the *DataWriter* calls **dispose()**. This is not true, because the dispose message needs to be propagated to *DataReaders*. This means that information about the instance—and the fact that it was disposed—is kept in the *DataWriter's* queue based on QoS policies such as [47.21 RELIABILITY QosPolicy on page 845](#), [47.9 DURABILITY QosPolicy on page 809](#), and [47.12 HISTORY QosPolicy on page 818](#). See [19.2.2 QoS Policies that Affect Instance Management on page 266](#) for more information on managing resources for instances.

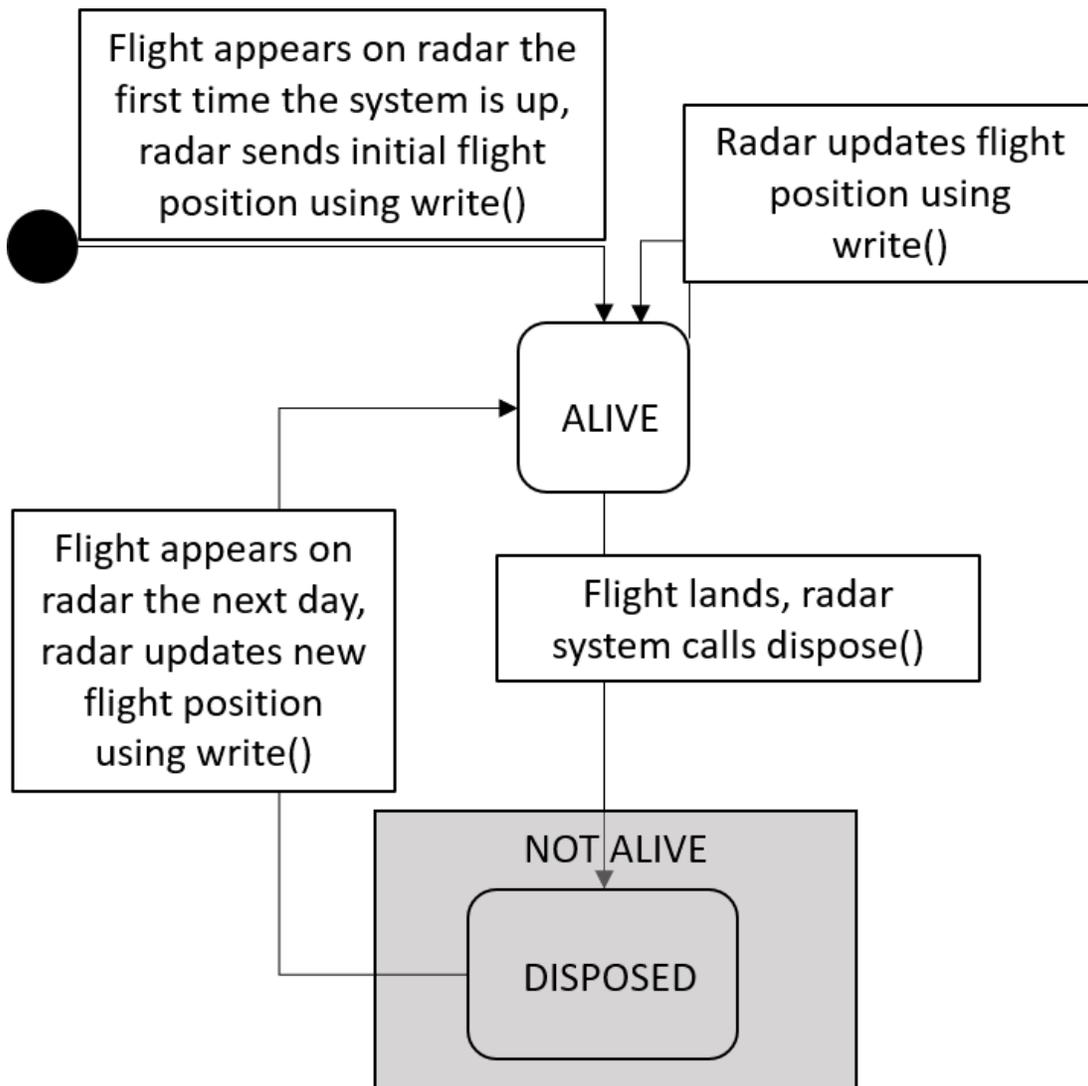

An instance can transition from **NOT\_ALIVE\_DISPOSED** to **ALIVE** if a *DataWriter* writes a new sample of that instance. An example of a system that transitions an instance to **NOT\_ALIVE\_DISPOSED** and then back to **ALIVE** is a radar system at an airport. It could be tracking a flight with the following key fields:

```
airline = UA
```

```
flight_num = 901
```

In this example, when the flight arrives on radar, the instance becomes **ALIVE**. When the flight lands, it becomes **NOT\_ALIVE\_DISPOSED**. The same flight flies every day, so it transitions from **NOT\_ALIVE\_DISPOSED** to **ALIVE** when the flight arrives again the next day. This maps to the state diagram shown in [Figure 19.2: Instance State Diagram: Example for Flight Data on the next page](#).

Figure 19.2: Instance State Diagram: Example for Flight Data

**Instances and OWNERSHIP QoS:** If the *DataWriters*' QoS policy is set to OWNERSHIP = EXCLUSIVE, the *DataWriter* with the highest OWNERSHIP\_STRENGTH that has written the instance is the owner of the instance. It is also the only *DataWriter* that can dispose the instance. It does not lose ownership by disposing. Other *DataWriters* can call **dispose()**, but their dispose will have no effect on the instance state. OWNERSHIP is generally used for redundancy purposes, so it makes sense for only one owning *DataWriter* at a time to affect the instance state. See [47.17 OWNERSHIP QoS Policy on page 833](#) for further details.

### 19.1.3 NOT\_ALIVE\_NO\_WRITERS Details

The NOT\_ALIVE\_NO\_WRITERS instance state indicates that there are no active *DataWriters* that are currently updating the instance.

An instance becomes **NOT\_ALIVE\_NO\_WRITERS** if all *DataWriters* that have written that instance have unregistered themselves from the instance or become not alive themselves (through losing liveliness, losing discovery liveliness, or being deleted). This means that if all *DataWriters* that have written samples for an instance are deleted, the instance changes state to **NOT\_ALIVE\_NO\_WRITERS**.

Currently the state transition from **NOT\_ALIVE\_NO\_WRITERS** to **ALIVE** happens only if new data is received, not if a previously-known writer is determined to be alive. Take for example a system where there is only a single *DataWriter* of an instance. If that *DataWriter* loses liveliness due to a temporary network disconnection, the *DataReaders* will detect that the instance is **NOT\_ALIVE\_NO\_WRITERS**. When the network disconnection is resolved, the *DataReaders* will detect that the *DataWriter* has regained liveliness, but will not change the instance state to **ALIVE** until the *DataWriter* sends a new sample of that instance.

### 19.1.4 Transitions between NOT\_ALIVE States

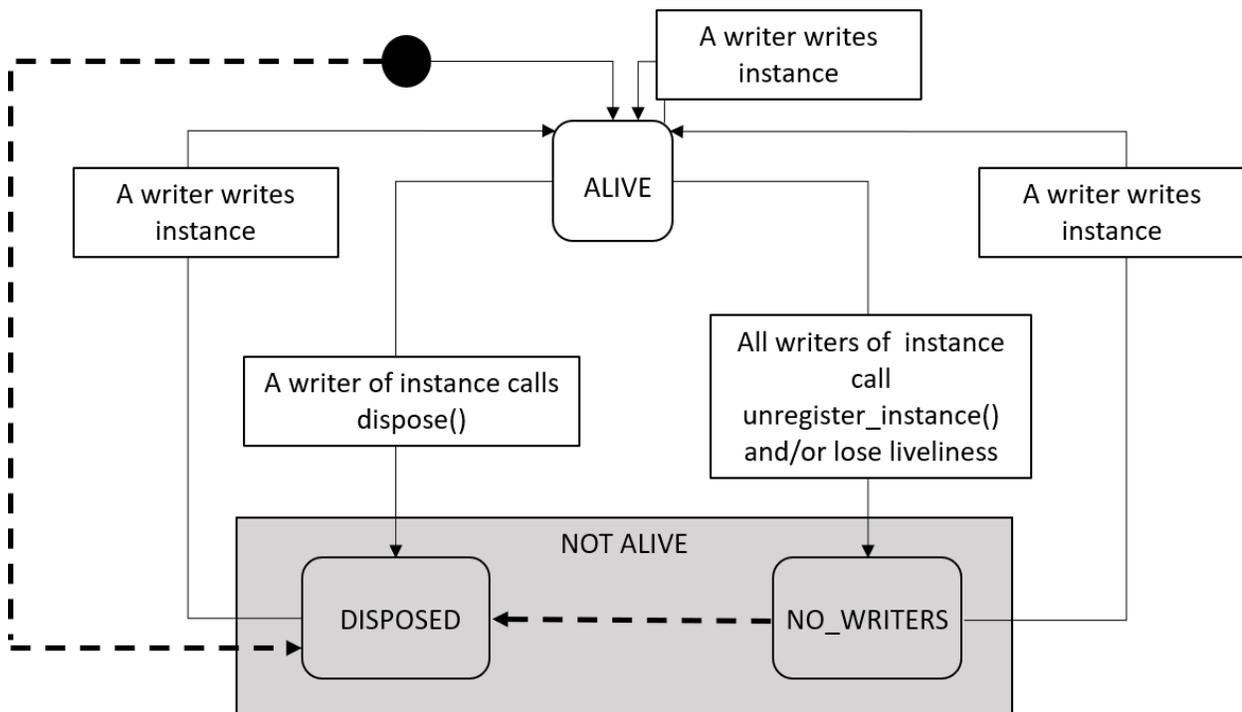

By default, there is no state transition between the **NOT\_ALIVE\_NO\_WRITERS** and **NOT\_ALIVE\_DISPOSED** states, but this can be overridden by using the QoS settings **propagate\_dispose\_of\_unregistered\_instances** and **propagate\_unregister\_of\_disposed\_instances** on a *DataReader* via the [48.1 DATA\\_READER\\_PROTOCOL QoS Policy \(DDS Extension\) on page 871](#).

Setting **propagate\_dispose\_of\_unregistered\_instances** to true means that if all *DataWriters* lose liveliness (so the instance becomes **NOT\_ALIVE\_NO\_WRITERS**), and then a *DataWriter* calls **dispose()** on the instance, the *DataReader* will recognize that instance as **NOT\_ALIVE\_DISPOSED** once the *DataWriter* regains liveliness.

Setting **propagate\_dispose\_of\_unregistered\_instances** to true could also mean that the first message a *DataReader* receives about an instance is **NOT\_ALIVE\_DISPOSED**. In [Figure 19.3: Instance State Transitions: propagate\\_dispose\\_of\\_unregistered\\_instances = true on the next page](#), there is a new initial state transition from a *DataReader* never having seen an instance to seeing it as **NOT\_ALIVE\_DISPOSED**. In this case, the *DataReader* recognizes that the instance went from never existing (as far as the *DataReader* is concerned) to **NOT\_ALIVE\_DISPOSED**.

It is recommended that if you set **propagate\_dispose\_of\_unregistered\_instances** to true, you also set **serialize\_key\_with\_dispose** to true (see [47.5 DATA\\_WRITER\\_PROTOCOL QoS Policy \(DDS Extension\) on page 788](#)). This QoS will allow the subscribing application to retrieve the key value of the instance through the **FooDataReader\_get\_key\_value** API, even though a valid sample for that instance has not been received.

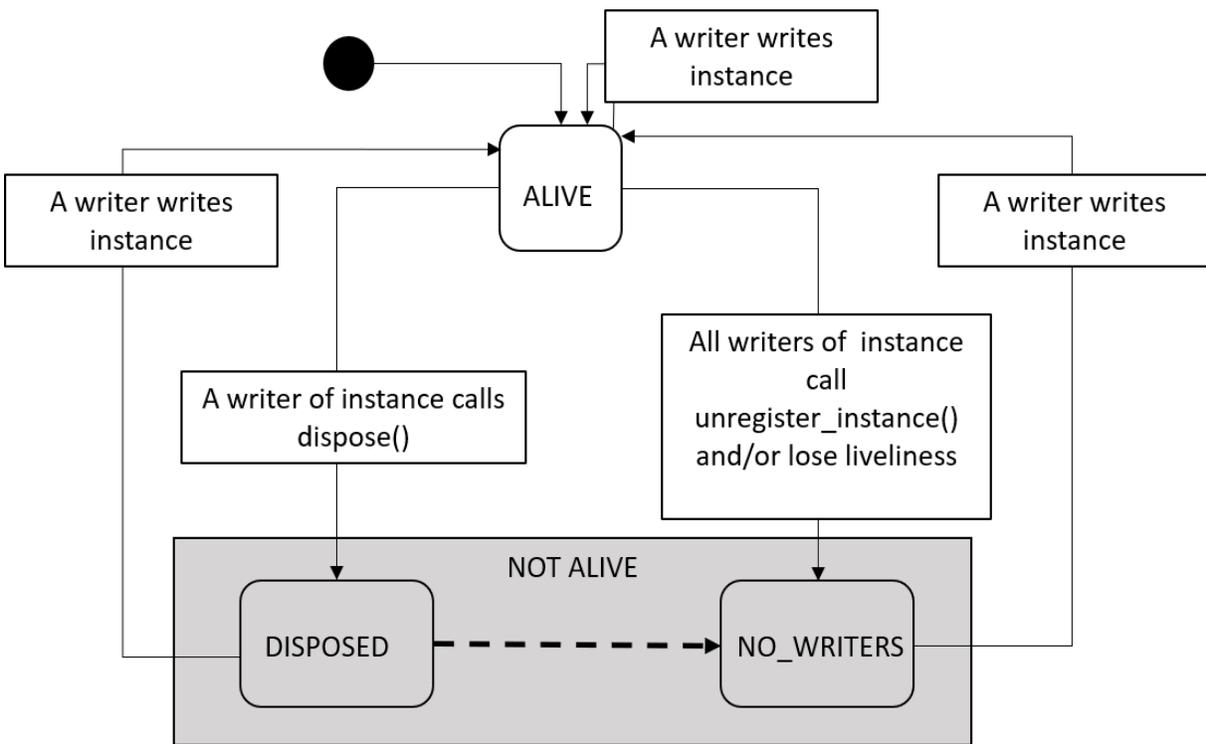

Figure 19.3: Instance State Transitions: `propagate_dispose_of_unregistered_instances = true`

Transitions shown with dashed lines are only available when `propagate_dispose_of_unregistered_instances = true`.

The `propagate_unregister_of_disposed_instances` QoS setting in the [48.1 DATA\\_READER\\_PROTOCOL QoS Policy \(DDS Extension\)](#) on page 871 allows instances to transition directly from the instance being disposed to **NOT\_ALIVE\_NO\_WRITERS**. See [Figure 19.4: Instance State Transitions: propagate\\_unregister\\_of\\_disposed\\_instances = true](#) on the next page. By default, only the resources for instances in the **NOT\_ALIVE\_NO\_WRITERS** instance state are reclaimable in the *DataReader* queue. In a system with finite instance resource limits, the `propagate_unregister_of_disposed_instances` setting allows an application to dispose instances to signal that the instance has gone away and then unregister those instances to make sure that the instances' resources are reclaimable for use by new instances. Depending on your system requirements, another approach to reclaiming instance resources in the *DataReader* queue is to set `autopurge_disposed_instances_delay` to zero. See [40.8.6 Instance Resource Limits and Memory Management](#) on page 649 for more details.

Figure 19.4: Instance State Transitions: `propagate_unregister_of_disposed_instances = true`

Transitions shown with dashed lines are only available when `propagate_unregister_of_disposed_instances = true`.

## 19.2 QoS Configuration and Instances

Some QoS policies are applied *per instance*, and other QoS policies configure instance management:

### 19.2.1 QoS Policies that are Applied per Instance

Several QoS policies (listed below) are applied per instance. This means that the QoS policy that's specified on the *DataWriter* or *DataReader* is applied separately for each instance created. QoS policies cannot be specified *uniquely* per instance, however. For example, if you are representing airline flights as different instances, you can't have a **DEADLINE period** of 1 second applied to one flight and a **DEADLINE period** of 2 seconds applied to another flight. The **DEADLINE period** (of, say, 1 second) is applied to *each flight*. In other words, you want to be notified if the flight position *DataReader* does not get an update about *each individual flight* within 1 second: the **DEADLINE period** is applied *per instance, for all instances*.

#### 19.2.1.1 DEADLINE QoS Policy

The [47.7 DEADLINE QoS Policy on page 804](#) is checked separately for every instance. When notified of a missed deadline, a *DataWriter* or *DataReader* can check the last instance that missed the deadline

using the instance handle in the status.

This allows a *DataWriter* to detect that it has not written a particular instance as frequently as it has offered in its deadline period, even if it has updated other instances.

This allows a *DataReader* to detect that it has not seen an update of an individual instance within the deadline period, even if it has seen updates from other instances during that time. This can be used to detect errors due to the *DataWriter* failing to write a particular instance. It can also detect network errors, where updates for a particular instance have been dropped or delayed.

### 19.2.1.2 DESTINATION\_ORDER QoSPolicy

The [47.8 DESTINATION\\_ORDER QoSPolicy on page 806](#) contains a configuration option that allows a *DataWriter* or *DataReader* to order data across the whole Topic for each instance.

### 19.2.1.3 HISTORY QoSPolicy

The [47.12 HISTORY QoSPolicy on page 818](#) **depth** is applied for each instance created. For example, if **depth** = 1, the *DataWriter* or *DataReader* will keep one sample for each instance.

This allows an application to specify how much history it wants to keep per instance for reliability purposes. For example, if data is modeled as state data—meaning that only the most recent sample of the data is important—the *DataWriter* and *DataReader* can set the history **depth** to 1. This allows them to send and receive only the most recent state for each instance.

### 19.2.1.4 DURABILITY QoSPolicy

The [47.9 DURABILITY QoSPolicy on page 809](#) **writer\_depth** is applied for each instance created. For example, if **writer\_depth** = 1, the *DataWriter* will keep one sample for each instance, for late-joining *DataReaders*.

This allows an application to specify how many samples it wants to keep per instance for later joiners. For example, if data is modeled as state data—meaning that only the most recent sample of the data is important—the *DataWriter* can set the **writer\_depth** to 1. This allows it to send only the most recent state for each instance to late-joining *DataReaders*.

### 19.2.1.5 PRESENTATION QoSPolicy

The [46.6 PRESENTATION QoSPolicy on page 760](#) contains a configuration option to determine the scope of coherency and ordering of data in the *DataReader*'s queue. If coherency is enabled, this allows a *Publisher* or *Subscriber* to specify whether each coherent set is per instance. If ordered access is enabled, this allows a *Publisher* or *Subscriber* to specify whether data should be ordered per Topic or per instance.

### 19.2.1.6 TIME\_BASED\_FILTER QosPolicy

The [48.4 TIME\\_BASED\\_FILTER QosPolicy on page 888](#) filters out samples of each instance that arrive within the specified **minimum\_separation**. For example, if the **minimum\_separation** is 1 second, the *DataReader* will receive samples of instance A at most once a second, and samples of instance B at most once a second. A sample of instance A may arrive immediately after a sample of instance B, and will not be filtered out.

## 19.2.2 QoS Policies that Affect Instance Management

There are additional QoS policies that affect instances, primarily by controlling the limits or memory growth of instances, or by controlling which instance information is sent over the network.

### 19.2.2.1 DataWriter and DataReader

The following policies affect both the *DataWriter* and *DataReader*.

#### 19.2.2.1.1 OWNERSHIP QosPolicy

If *DataWriters* have [47.17 OWNERSHIP QosPolicy on page 833](#) set to EXCLUSIVE, a *DataWriter* with higher OWNERSHIP\_STRENGTH is the owner of any instances it writes. If a *DataWriter* calls **unregister\_instance()**, it gives up ownership of the instance. If it calls **dispose()**, it does not give up ownership of the instance, so no other *DataWriter* can update that instance or its state.

#### 19.2.2.1.2 RESOURCE\_LIMITS QosPolicy

The [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#) contains a field named **max\_instances** that controls the maximum number of instances that may be stored for the *DataWriter* or *DataReader*.

### 19.2.2.2 DataWriter

The following policies apply to the *DataWriter*.

#### 19.2.2.2.1 OWNERSHIP\_STRENGTH QosPolicy

The *DataWriter* with highest [47.18 OWNERSHIP\\_STRENGTH QosPolicy on page 836](#) will own the instances that it writes. This means that if a lower-strength *DataWriter* attempts to update any of those instances by writing or calling dispose on the instance, it does not affect the instance or its state.

#### 19.2.2.2.2 DATA\_WRITER\_RESOURCE\_LIMITS QosPolicy

The **instance\_replacement** and **replace\_empty\_instances** fields in the [47.6 DATA\\_WRITER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 800](#) control how instances can be replaced and the memory reclaimed if **max\_instances** is reached. See [47.6.1 Configuring DataWriter Instance Replacement on page 802](#) for more information.

The **autoregister\_instances** field controls whether to automatically register instances when a non-NIL handle is passed to the **write()** call.

#### 19.2.2.2.3 WRITER\_DATA\_LIFECYCLE QoS Policy

The **autodispose\_unregistered\_instances** field in the [47.31 WRITER\\_DATA\\_LIFECYCLE QoS Policy on page 866](#) controls whether a *DataWriter* automatically disposes instances when they are unregistered. (By default, it doesn't.)

The **autopurge\_unregistered\_instances\_delay** and **autopurge\_disposed\_instances\_delay** fields control whether/when a *DataWriter* purges instances if they are NOT\_ALIVE\_NO\_WRITERS or NOT\_ALIVE\_DISPOSED. Once all samples for an instance have been fully acknowledged by existing *DataReaders*, both the instance and the samples for that instance will be purged (see [31.8.2 write\(\) behavior with KEEP\\_LAST and KEEP\\_ALL on page 413](#) for a definition of "fully ACK'ed").

See [31.14.7 Instance Memory Management on page 430](#) for more information on how this affects *DataWriter* memory usage.

#### 19.2.2.2.4 DATA\_WRITER\_PROTOCOL QoS Policy

The **disable\_inline\_keyhash** field in the [47.5 DATA\\_WRITER\\_PROTOCOL QoS Policy \(DDS Extension\) on page 788](#) controls whether or not a keyhash is propagated on the wire with each sample. This field allows the user to control whether bandwidth is used to send the keyhash with every sample, or CPU is used by the subscribing application to calculate the keyhash for every sample.

The **serialize\_key\_with\_dispose** field controls whether or not the serialized key is propagated on the wire with dispose samples. This field is useful when **propagate\_dispose\_of\_unregistered\_instances** in the [48.1 DATA\\_READER\\_PROTOCOL QoS Policy \(DDS Extension\) on page 871](#) is also true.

### 19.2.2.3 DataReader

The following policies apply to the *DataReader*.

#### 19.2.2.3.1 DATA\_READER\_PROTOCOL QoS Policy

The **propagate\_unregister\_of\_disposed\_instances** and **propagate\_dispose\_of\_unregistered\_instances** fields in the [48.1 DATA\\_READER\\_PROTOCOL QoS Policy \(DDS Extension\) on page 871](#) control whether a *DataReader* can see state transitions between NOT\_ALIVE instance states. See [19.1 Instance States on page 258](#) for more information.

#### 19.2.2.3.2 DATA\_READER\_RESOURCE\_LIMITS QoS Policy

The **initial\_remote\_writers\_per\_instance** and **max\_remote\_writers\_per\_instance** fields in the [48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QoS Policy \(DDS Extension\) on page 876](#) control the number of *DataWriters* from which a *DataReader* may receive samples for a single instance.

The **max\_total\_instances** field controls the maximum number of instances that a *DataReader* will maintain state for. See [40.8.6 Instance Resource Limits and Memory Management on page 649](#) for more information.

The **max\_remote\_virtual\_writers\_per\_instance** field controls the maximum number of virtual remote writers that can be associated with an instance.

The **instance\_replacement** field controls how instances can be replaced and the memory reclaimed if **max\_instances** is reached. See [48.2.3 Configuring DataReader Instance Replacement on page 882](#) for more information.

#### 19.2.2.3.3 READER\_DATA\_LIFECYCLE QoS Policy

The **autopurge\_nowriter\_samples\_delay** and **autopurge\_disposed\_samples\_delay** fields in the [48.3 READER\\_DATA\\_LIFECYCLE QoS Policy on page 885](#) control whether/when to purge samples that are associated with instances in the **NOT\_ALIVE\_NO\_WRITERS** or **NOT\_ALIVE\_DISPOSED** states, freeing up queue space and allowing instance information to be purged.

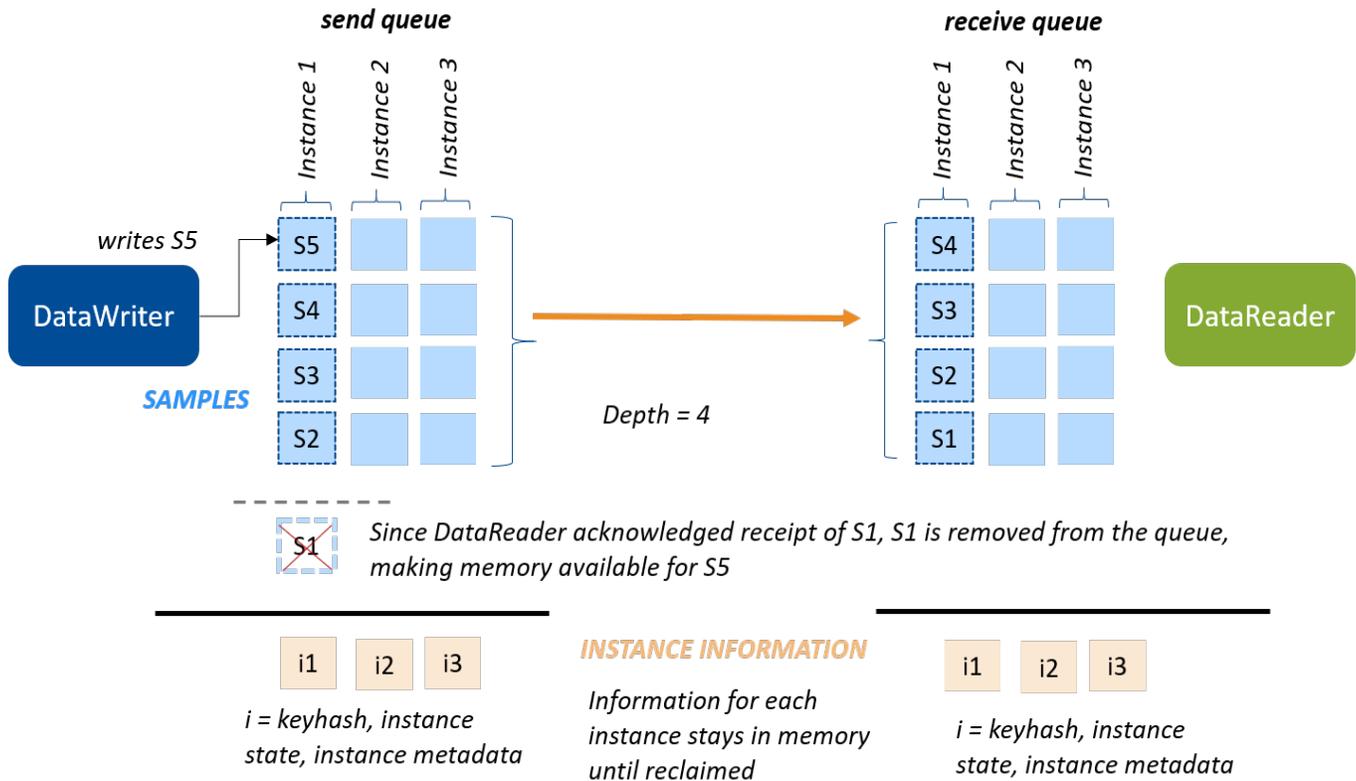

The **autopurge\_disposed\_instances\_delay** field controls whether to purge instance memory when an instance becomes **NOT\_ALIVE\_DISPOSED**. The **autopurge\_nowriter\_instances\_delay** field controls whether to purge instance memory when an instance becomes **NOT\_ALIVE\_NOWRITERS**.

## 19.3 Instance Metadata Memory Management

When an application creates keyed *DataWriters* and *DataReaders* (these are *DataWriters* and *DataReaders* whose *Topics* are keyed), *Connex* needs to allocate memory for instance metadata. (Such metadata is not required for non-keyed data.) This includes memory for instance-specific metadata such as maintaining the current state of each instance and memory for instance keyhashes. Keyhashes are 16-byte representations of unique instances that are sent along with a sample. They allow *DataWriters* and *DataReaders* to quickly identify each unique instance without comparing all individual key fields.

The memory used for instance metadata is separate from sample memory and serialized keys (see [Chapter 20 Sample and Instance Memory Management on page 271](#)). A *DataWriter* or *DataReader* may have metadata stored for an instance even if there are currently no samples in the *DataWriter's* or *DataReader's* queue. Furthermore, memory related to instance metadata is not deleted, but reclaimed. How memory is reclaimed for instances depends on how your QoS is set, and those QoS settings differ between *DataWriters* and *DataReaders*. For example, disposing an instance does not necessarily free up memory, depending on how your QoS is configured. (By default, the QoS settings do not free instance memory when instances are disposed.)

Figure 19.5: Comparing Sample Memory and Instance Memory

Consider a reliable, volatile *DataWriter* that writes a sample of an instance for the first time. The *DataWriter* stores the sample in its queue. At the same time, the *DataWriter* stores the keyhash for that instance, the state of the instance (**ALIVE**), and additional metadata about the instance. All matching *DataReaders* acknowledge the sample, so the *DataWriter* removes the sample from its queue, allowing that memory to be reused by another sample; however, the instance metadata is still valid, and continues to be stored.

Similarly, when each *DataReader* receives the first update about an instance, it stores the sample in its queue; it also stores the instance's keyhash and state (**ALIVE**), and additional metadata about the instance. When the *DataReader* takes the sample from the queue, the sample is removed from the queue, allowing that memory to be reused by another sample; however, the instance metadata is still valid and continues to be stored.

Details on how *DataWriters* and *DataReaders* allocate and reclaim memory for instances can be found in the following sections:

- Details on the QoS policies that configure memory management on *DataWriters* are covered in [31.14.7 Instance Memory Management on page 430](#).

- Details on the QoS that configure memory management on *DataReaders* are covered in [40.8.6 Instance Resource Limits and Memory Management](#) on page 649.

# Chapter 20 Sample and Instance Memory Management

This chapter describes how *Connex* manages the memory for the DDS data samples that are sent by *DataWriters* and received by *DataReaders*.

## 20.1 Sample Memory Management for DataWriters

To configure DDS sample memory management on the writer side, use the [47.19 PROPERTY QosPolicy \(DDS Extension\) on page 837](#). [Table 20.1 DDS Sample Memory Management Properties for DataWriters](#) lists the supported memory-management properties for *DataWriters*. This section applies to *DataWriters* that use IDL-generated type-plugins as well as *DynamicDataWriters*.

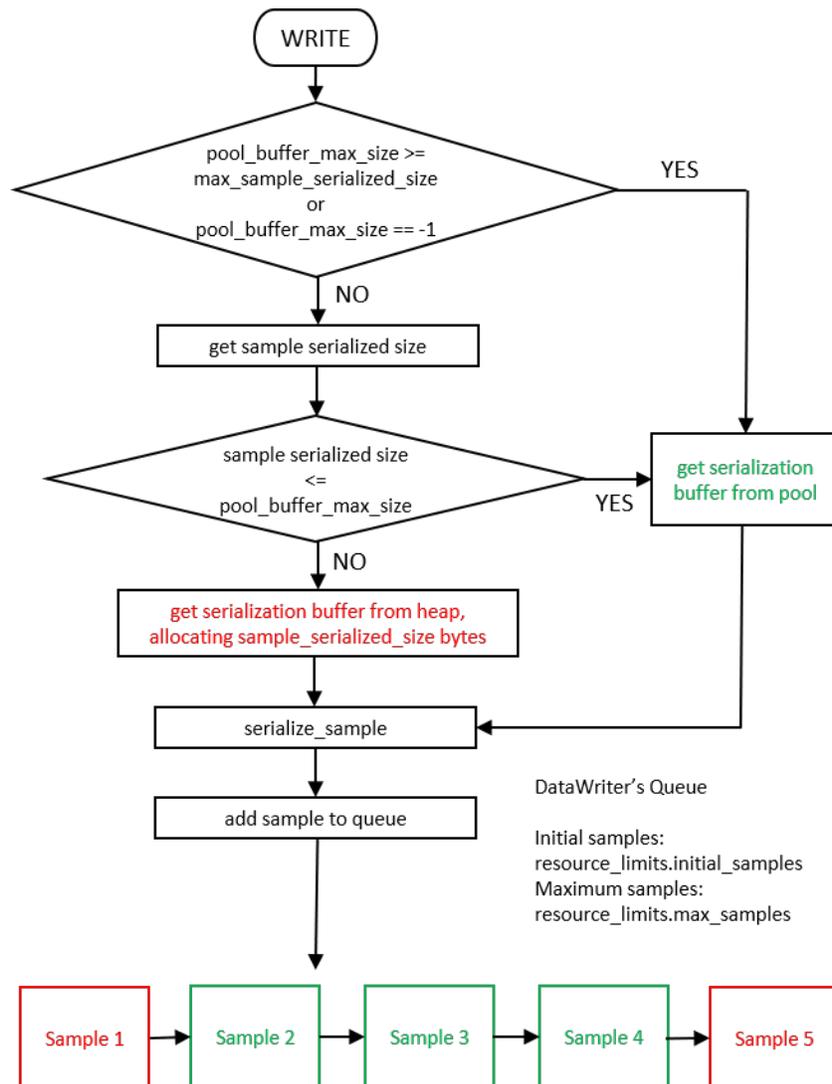

Table 20.1 DDS Sample Memory Management Properties for DataWriters

Property	Description
dds.data_writer. history.memory_ manager. fast_pool.pool_buf- fer_max_size	<p>If the serialized size of the DDS sample is <math>\leq</math> <b>pool_buffer_max_size</b>:            The buffer is obtained from a pre-allocated pool and released when the <i>DataWriter</i> is deleted. The pre-allocated pool is sized based on <b>initial_samples/max_samples</b> (see <a href="#">47.22 RESOURCE_LIMITS QoSPolicy on page 850</a>). The pool allocates <b>initial_samples</b> buffers at first and can grow up to <b>max_samples</b> buffers.</p> <p>If the serialized size of the DDS sample is <math>&gt;</math> <b>pool_buffer_max_size</b>:            The buffer is dynamically allocated from the heap and returned to the heap when the DDS sample is removed from the <i>DataWriter</i>'s queue. The size of the buffer allocated from the heap is the sample serialized size.</p> <p>Default: -1 (UNLIMITED). All DDS sample buffers are obtained from the pre-allocated pool; the buffer size is the maximum serialized size of the DDS samples, as returned by the type plugin <b>get_serialized_sample_max_size()</b> operation.</p> <p>Notes:</p> <ul style="list-style-type: none"> <li>• If you use unbounded sequences or strings, then you should set <b>pool_buffer_max_size</b> to a finite value. See <a href="#">17.1.1 Sequences on page 113</a>.</li> <li>• The <b>pool_buffer_max_size</b> also controls the memory allocation for the serialized key buffer that is stored with every instance. See <a href="#">20.3 Instance Memory Management for DataWriters on page 285</a>.</li> </ul> <p>See <a href="#">20.1.1 Memory Management without Batching</a> below.</p>
dds.data_writer. history.memory_ manager. java_stream.min_ size	<p>Only supported when using the Java API.</p> <p>Defines the minimum size of the buffer that will be used to serialize DDS samples.</p> <p>When a <i>DataWriter</i> is created, the Java layer will allocate a buffer of this size and associate it with the <i>DataWriter</i>.</p> <p>Default: -1 (UNLIMITED). This is a sentinel that refers to the maximum serialized size of a DDS sample, as returned by the type plugin <b>get_serialized_sample_max_size()</b> operation</p> <p>See <a href="#">20.1.3 Writer-Side Memory Management when Using Java on page 276</a>.</p>
dds.data_writer. history.memory_ manager. java_stream.trim_ to_size	<p>Only supported when using the Java API.</p> <p>A boolean value that controls the growth of the serialization buffer.</p> <p>If set to 0 (default): The buffer will not be reallocated unless the serialized size of a new DDS sample is greater than the current buffer size.</p> <p>If set to 1: The buffer will be reallocated with each new DDS sample to a smaller size in order to just fit the DDS sample serialized size. The new size cannot be smaller than <b>min_size</b>.</p> <p>See <a href="#">20.1.3 Writer-Side Memory Management when Using Java on page 276</a>.</p>

## 20.1.1 Memory Management without Batching

When the **write()** operation is called on a *DataWriter* that does not have batching enabled, the *DataWriter* serializes (marshals) the input DDS sample and stores it in the *DataWriter*'s queue (see [Figure 20.1: DataWriter Actions when Batching is Disabled on the next page](#)). The size of this queue is limited by **initial\_samples/max\_samples** in the [47.22 RESOURCE\\_LIMITS QoSPolicy on page 850](#).

Figure 20.1: DataWriter Actions when Batching is Disabled

Each DDS sample in the queue has an associated serialization buffer in which the *DataWriter* will serialize the DDS sample. This buffer is either obtained from a pre-allocated pool (if the serialized size of the DDS sample is  $\leq$  `dds.data_writer.history.memory_manager.fast_pool.pool_buffer_max_size`) or the buffer is dynamically allocated from the heap (if the serialized size of the DDS sample is  $>$  `dds.data_writer.history.memory_manager.fast_pool.pool_buffer_max_size`). The size of the buffer allocated on the heap is the sample serialized size. See [Table 20.1 DDS Sample Memory Management Properties for DataWriters](#).

The default value of `pool_buffer_max_size` is -1 (UNLIMITED). In this case, all the DDS samples come from the pre-allocated pool and the size of the buffers is the maximum serialized size of the DDS samples as returned by the type plugin `get_serialized_sample_max_size()` operation. The default value is optimum for real-time applications where determinism and predictability is a must. The trade-off is higher memory usage, especially in cases where the maximum serialized size of a DDS sample is large.

If the maximum serialized size of a DDS sample is large, but bounded, the value can be set to a finite value to save memory. If the maximum serialized size is unbounded, then the value must be set to a finite value in order to avoid running out of system memory while allocating the sample pools.

The pre-allocated pool of buffers is sized based on **initial\_samples**/**max\_samples** (see [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#)). The pool allocates **initial\_samples** buffers at first and can grow up to **max\_samples** buffers.

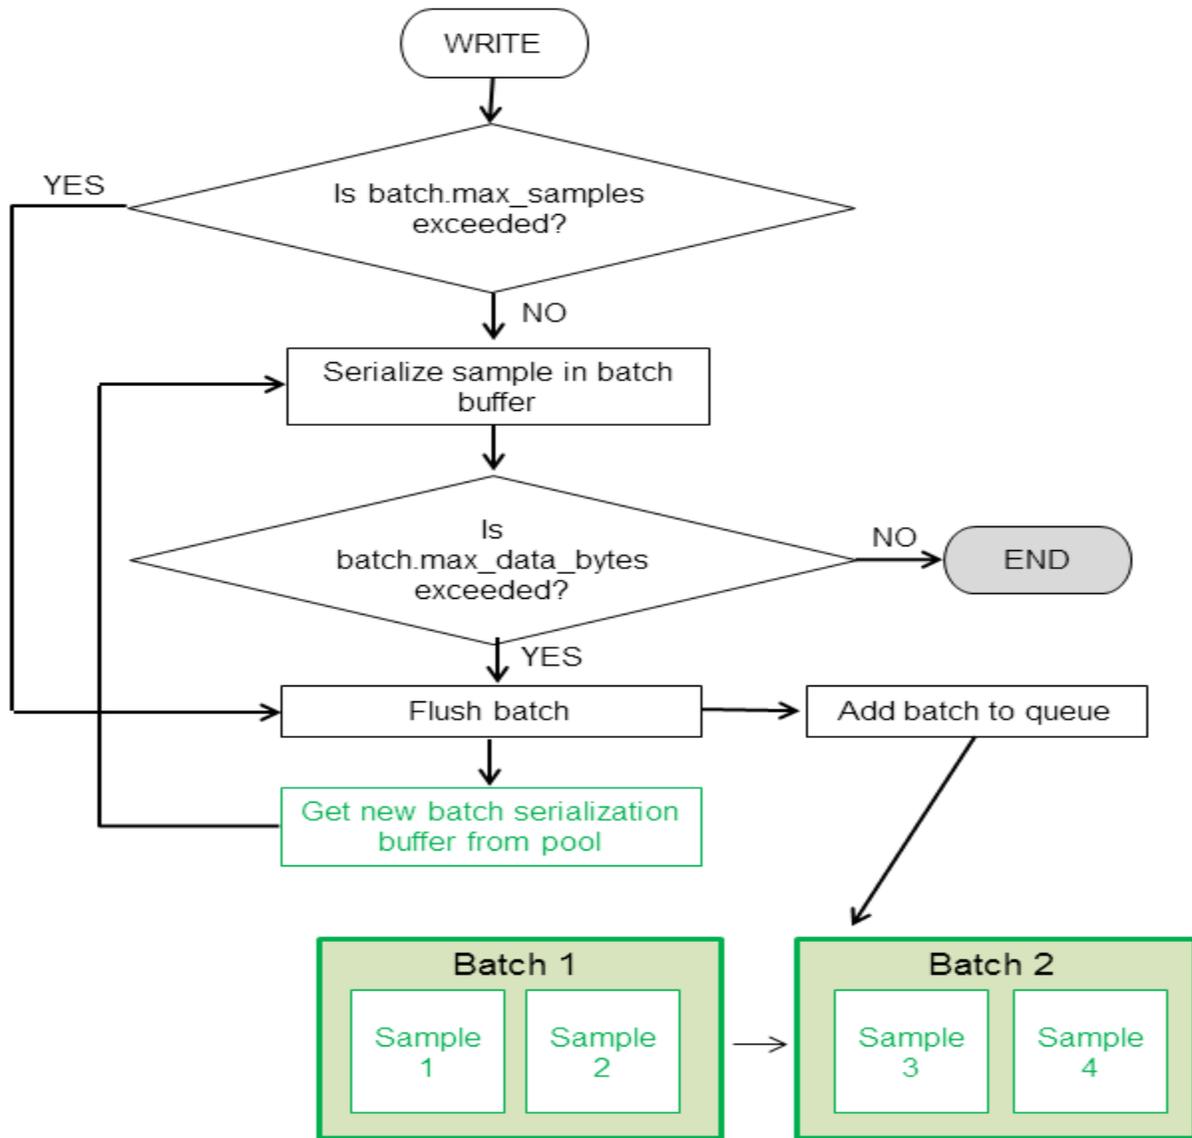

*Connex* cannot send arbitrarily large samples. For details on serialization limits see [17.10 Data Sample Serialization Limits on page 245](#).

## 20.1.2 Memory Management with Batching

When the **write()** operation is called on a *DataWriter* for which batching is enabled (see [47.2 BATCH QosPolicy \(DDS Extension\) on page 773](#)), the *DataWriter* serializes (marshals) the input DDS sample into the current batch buffer (see [Figure 20.2: DataWriter Actions when Batching is Enabled on the next page](#)). When the batch is flushed, it is stored in the *DataWriter*'s queue along with its DDS samples. The *DataWriter* queue can be sized based on:

- The number of DDS samples, using **initial\_samples**/**max\_samples** (both set in the [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#))
- The number of batches, using **initial\_batches**/**max\_batches** (both set in the [47.6 DATA\\_WRITER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 800](#))
- Or a combination of **max\_samples** and **max\_batches**

Figure 20.2: DataWriter Actions when Batching is Enabled

DataWriter's Queue

Initial samples:

`resource_limits.initial_samples`

Maximum samples:

`resource_limits.max_samples`

Initial batches:

`writer_resource_limits.initial_batches`

Maximum batches:

`writer_resource_limits.max_batches`

When batching is enabled, the memory associated with the batch buffers always comes from a pre-allocated pool. The size of the buffers is determined by the QoS values **max\_samples** and **max\_data\_bytes** (both set in the [47.2 BATCH QoS Policy \(DDS Extension\) on page 773](#)) as follows:

- If **max\_data\_bytes** is a finite value, the size of the buffer is the maximum of this value and the maximum serialized size of a DDS sample (**max\_sample\_serialized\_size**) as returned by the type-plugin **get\_serialized\_sample\_max\_size()**, since that batch must contain at least one DDS sample.
- Otherwise, the size of the buffer is calculated by **(batch.max\_samples \* max\_sample\_serialized\_size)**.

Notice that for variable-size DDS samples (for example, DDS samples containing sequences) it is good practice to size the buffer based on **max\_data\_bytes**, since this leads to more efficient memory usage.

**Note:** The value of the property **dds.data\_writer.history.memory\_manager.fast\_pool.pool\_buffer\_max\_size** is ignored by *DataWriters* with batching enabled.

### 20.1.3 Writer-Side Memory Management when Using Java

When the Java API is used, *Connex* allocates a Java buffer per *DataWriter*; this buffer is used to serialize the Java DDS samples published by the *DataWriters*. After a DDS sample is serialized into a Java buffer, the result is copied into the underlying native buffer described in [20.1.1 Memory Management without Batching on page 272](#) and [20.1.2 Memory Management with Batching on page 274](#).

You can use the following two *DataWriter* properties to control memory allocation for the Java buffers that are used for serialization (see [Table 20.1 DDS Sample Memory Management Properties for DataWriters](#)):

- **dds.data\_writer.history.memory\_manager.java\_stream.min\_size**
- **dds.data\_writer.history.memory\_manager.java\_stream.trim\_to\_size**

### 20.1.4 Writer-Side Memory Management when Working with Large Data

*Large DDS samples* are DDS samples with a large *maximum* size relative to the memory available to the application. Notice the use of the word *maximum*, as opposed to *actual* size.

As described in [20.1.1 Memory Management without Batching on page 272](#), by default, the middleware preallocates the DDS samples in the *DataWriter* queue to their maximum serialized size. This may lead to high memory-usage in *DataWriters* where the maximum serialized size of a DDS sample is large.

For example, let's consider a video conferencing application:

```
struct VideoFrame {
    boolean keyFrame;
```

```
sequence<octet,1024000> data;
};
```

The above IDL definition can be used to work with video streams.

Each frame is transmitted as a sequence of octets with a maximum size of 1 MB. In this example, the video stream has two types of frames: I-Frames (also called key frames) and P-Frames (also called delta frames). I-Frames represent full images and do not require information about the preceding frames in order to be decoded. P-frames require information about the preceding frames in order to be decoded.

A video stream consists of a sequence of frames in which I-Frames are followed by multiple P-frames. The number of P-frames between I-Frames affects the video quality since, in a non-reliable configuration, losing a P-frame will degrade the image quality until the next I-frame is received.

For our use case, let's assume that I-frames may require 1 MB, while P-Frames require less than 32 KB. Also, there are 20 times more P-Frames than I-Frames.

Although the actual size of the frames sent by the *Connex* application is usually significantly smaller than 1 MB since they are P-Frames, the default memory management will use 1 MB per frame in the *DataWriter* queue. If **resource\_limits.max\_samples** is 256, the *DataWriter* may end up allocating 256 MB.

Using some domain-specific knowledge, such as the fact that most of the P-Frames have a size smaller than 32 KB, we can optimize memory usage in the *DataWriter's* queue while still maintaining determinism and predictability for the majority of the frames sent on the wire.

The following XML file shows how to optimize the memory usage for the previous example (rather than focusing on efficient usage of the available network bandwidth).

```
<?xml version="1.0"?>
<!-- XML QoS Profile for large data -->
<dds xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <!-- QoS Library containing the QoS profile used for large data -->
  <qos_library name="ReliableLargeDataLibrary">
    <!-- QoS profile to optimize memory usage in DataWriters sending
    large images
    -->
    <qos_profile name="ReliableLargeDataProfile"
      is_default_qos="true">
      <!-- QoS used to configure the DataWriter -->
      <datawriter_qos>
        <resource_limits>
          <max_samples>32</max_samples>
          <!-- No need to pre-allocate 32 images unless needed -->
          <initial_samples>1</initial_samples>
        </resource_limits>

        <property>
          <value>
            <!-- For frames with size smaller or
```

```

        equal to 33 KB the serialization
        buffer is obtained from a
        pre-allocated pool. For sizes
        greater than 33 KB, the DataWriter
        will use dynamic memory allocation.
    -->
    <element>
      <name>
dds.data_writer.history.memory_manager.fast_pool.pool_buffer_max_size
      </name>
      <value>33792</value>
    </element>
    <!-- Java will use a 33 KB buffer to
        serialize all frames with a size
        smaller than or equal to 33 KB.
        When an I-frame is published,
        Java will reallocate the
        serialization buffer to match
        the serialized size of the new frame.
    -->
    <element>
      <name>
dds.data_writer.history.memory_manager.java_stream.min_size
      </name>
      <value>33792</value>
    </element>
    <element>
      <name>
dds.data_writer.history.memory_manager.java_stream.trim_to_size
      </name>
      <value>1</value>
    </element>
  </value>
</property>
</datawriter_qos>
</qos_profile>
</qos_library>
</dds>

```

Working with large data DDS samples will likely require throttling the network traffic generated by single DDS samples. For additional information on shaping network traffic, see [34.4 FlowControllers \(DDS Extension\) on page 532](#).

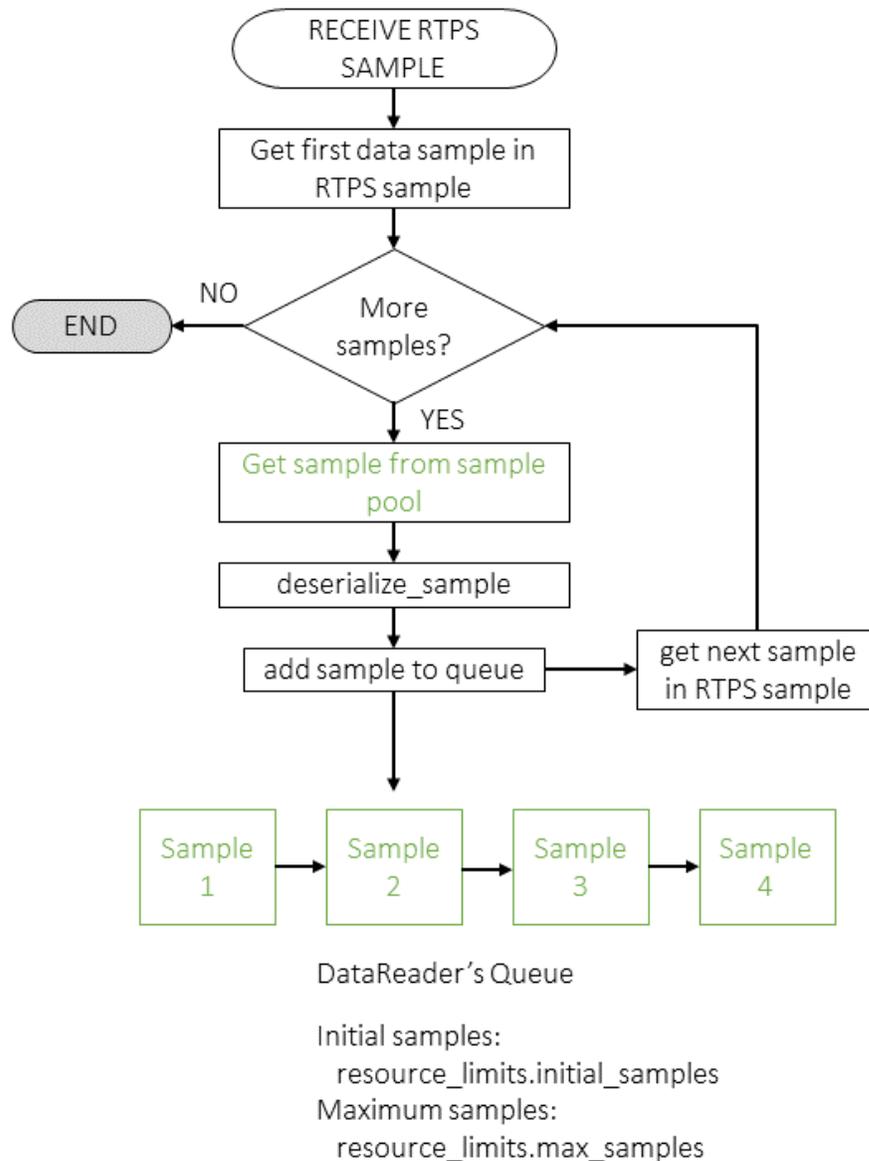

## 20.2 Sample Memory Management for DataReaders

The DDS data samples received by a *DataReader* are deserialized (demarshaled) and stored in the *DataReader*'s queue (see [Figure 20.3: Adding DDS Samples to DataReader's Queue on the next page](#)). The size of this queue is limited by **initial\_samples/max\_samples** in the [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#).

## 20.2.1 Memory Management for DataReaders Using Generated Type-Plugins

Figure 20.3: Adding DDS Samples to DataReader's Queue below shows how DDS samples are processed and added to the *DataReader's* queue.

Figure 20.3: Adding DDS Samples to DataReader's Queue

The RTPS DATA DDS samples received by a *DataReader* can be either batch DDS samples or individual DDS samples. The *DataReader* queue does not store batches. Therefore, each one of the DDS samples within a batch will be deserialized and processed individually.

When the *DataReader* processes a new sample, it will deserialize it into a sample obtained from a pre-allocated pool. By default, to provide predictability and determinism, the sample obtained from the pool

is allocated to its maximum size. For example, with the following IDL type, each sample in the *DataReader* queue will consume 1 MB, even if the actual size is smaller.

```
struct VideoFrame {
    boolean keyFrame;
    sequence<octet,1024000> data;
};
```

In the above example, it is possible to reduce the memory consumption by declaring the data sequence as unbounded and by generating code for the type with the command-line option **-unboundedSupport**. In this case, the middleware will not preallocate 1 MB for the data member. Instead, the generated code will deserialize incoming samples by dynamically allocating and deallocating memory to accommodate the actual size of the data sequence.

## 20.2.2 Reader-Side Memory Management when Using Java

When the Java API is used with *DataReaders* using generated type-plugins, *Connex* allocates a Java buffer per *DataReader*; this buffer is used to copy the native serialized data, so that the received DDS samples can be deserialized into the Java objects obtained from the DDS sample pool in [Figure 20.3: Adding DDS Samples to DataReader's Queue on the previous page](#).

You can use the *DataReader* properties in [Table 20.2 DDS Sample Memory Management Properties for DataReaders when Using Java API](#) to control memory allocation for the Java buffer used for deserialization:

**Table 20.2 DDS Sample Memory Management Properties for DataReaders when Using Java API**

Property	Description
dds.data_reader.history.memory_manager.java_stream.min_size	<p><b>Only supported when using the Java API.</b></p> <p>Defines the minimum size of the buffer used for the serialized data.</p> <p>When a <i>DataReader</i> is created, the Java layer will allocate a buffer of this size and associate it with the <i>DataReader</i>.</p> <p>Default: -1 (UNLIMITED) This is a sentinel to refer to the maximum serialized size of a DDS sample, as returned by the type plugin method <b>get_serialized_sample_max_size()</b>.</p>
dds.data_reader.history.memory_manager.java_stream.trim_to_size	<p><b>Only supported when using the Java API.</b></p> <p>A Boolean value that controls the growth of the deserialization buffer.</p> <p>If set to 0 (the default), the buffer will not be re-allocated unless the serialized size of a new DDS sample is greater than the current buffer size.</p> <p>If set to 1, the buffer will be re-allocated with each new DDS sample in order to just fit the DDS sample serialized size. The new size cannot be smaller than <b>min_size</b>.</p>

## 20.2.3 Memory Management for DynamicData DataReaders

Unlike *DataReaders* that use generated type-plugin code, *DynamicData DataReaders* provide configuration mechanisms to control the memory usage for use cases involving large data DDS samples. It is not required to set any of the following properties in order to support unbounded types in your

application. The default behavior for a DynamicData *DataReader* is that samples are allocated to the minimum deserialized size and can grow to any size required to store incoming samples.

A DDS DynamicData sample stored in the *DataReader*'s queue has an associated underlying buffer that contains the DynamicData-specific representation of the DDS sample. The buffer is allocated according to the configuration provided in the **data** and **serialization** members of the **DynamicDataTypeProperty\_t** used to create the **DynamicDataTypeSupport** (see [17.8 Interacting Dynamically with User Data Types on page 236](#)).

```
struct DDS_DynamicDataTypeProperty_t {
    DDS_DynamicDataProperty_t data;
    DDS_DynamicDataTypeSerializationProperty_t serialization;
};

struct DDS_DynamicDataTypeSerializationProperty_t {
    DDS_Boolean trim_to_size;
}

struct DDS_DynamicDataProperty_t {
    DDS_Long buffer_initial_size;
    DDS_Long buffer_max_size;
};
```

[Table 20.3 struct DDS\\_DynamicDataTypeSerializationProperty\\_t below](#) describes the member of DDS\_DynamicDataTypeSerializationProperty\_t.

**Table 20.3 struct DDS\_DynamicDataTypeSerializationProperty\_t**

Name	Description
trim_to_size	<p>Controls the growth of the serialization buffer in a DynamicData object.</p> <p>This property only applies to DynamicData samples that are obtained from the sample pool that is created by each DynamicData <i>DataReader</i>.</p> <p>If set to 0 (default): The buffer will not be reallocated unless the deserialized size of the incoming DDS sample is greater than the current buffer size.</p> <p>If set to 1: The buffer of a DynamicData object obtained from the DDS sample pool will be re-allocated for each sample to just fit the size of the deserialized data of the incoming sample. The newly allocated size will not be smaller than <b>max(min_deserialized_size, buffer_initial_size)</b>.</p>

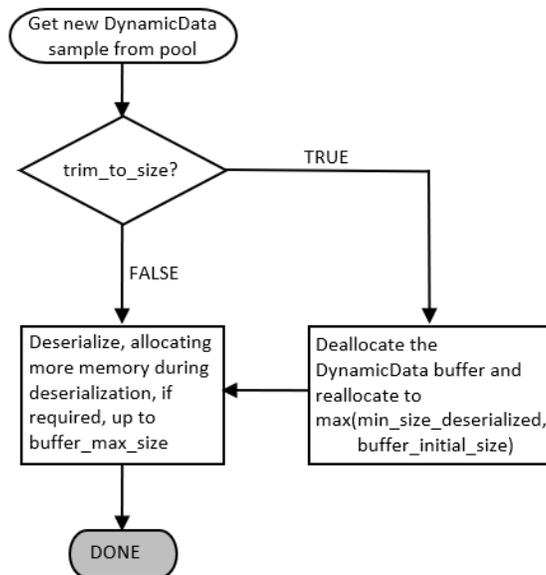

The following table describes the members of DDS\_DynamicDataProperty\_t.

Table 20.4 struct DDS\_DynamicDataProperty\_t

Name	Description
buffer_initial_size	<p>The initial amount of memory used by the underlying DynamicData buffer, in bytes.</p> <p>This property is used to configure the DynamicData objects that are created stand-alone as well as the DynamicData samples that are obtained from the sample pool that is created by each DynamicData <i>DataReader</i>.</p> <p>If set to 0 (default): The initial buffer size will be set to the minimum amount of space required to hold the overhead required by the DynamicData internal representation (about 100 bytes) in addition to the minimum deserialized size of a sample. The minimum deserialized size of a sample assumes that all strings are allocated to their default values, sequences are left to length 0, and all optional members are unset.</p> <p>If set to any value other than 0: The underlying buffer will be allocated to the provided size plus the overhead required by the DynamicData internal representation (about 100 bytes). If the provided size plus the overhead is less than the size used when <b>buffer_initial_size</b> is left to 0, then the default value is used.</p>
buffer_max_size	<p>The maximum amount of memory that the underlying DynamicData buffer may use, in bytes.</p> <p>This property is used to configure the DynamicData objects that are created stand-alone as well as the DynamicData samples that are obtained from the sample pool that is created by each DynamicData <i>DataReader</i>. A DynamicData object will grow to this size from the initial size as needed. The <b>buffer_max_size</b> includes all overhead that is required for the internal DynamicData representation and therefore represents a hard upper limit on the size of the underlying DynamicData buffer.</p> <p>If set to -1 (default): The buffer will grow unbounded to the size required to fit all members.</p> <p>If set to any value other than -1: The buffer will not grow beyond this size. If setting a member's values requires the buffer to grow beyond the maximum, the member will fail to be set. If the buffer is required to grow beyond this maximum during deserialization, the sample will fail to be deserialized. The <b>buffer_max_size</b> cannot be smaller than the <b>buffer_initial_size</b>.</p>

Figure 20.4: Allocation of DDS Samples in DataReader Queue for DynamicData DataReaders below shows how DDS samples are allocated in the *DataReader* queue for DynamicData *DataReaders*.

Figure 20.4: Allocation of DDS Samples in DataReader Queue for DynamicData DataReaders

## 20.2.4 Memory Management for Fragmented DDS Samples

When a *DataWriter* writes DDS samples with a serialized size greater than the minimum of the largest transport message sizes across all transports installed with the *DataWriter*, the DDS samples are fragmented into multiple RTPS fragment messages.

The different fragments associated with a DDS sample are assembled in the *DataReader* side into a single buffer that will contain the DDS sample serialized data after the last fragment is received.

By default, the *DataReader* keeps a pool of pre-allocated serialization buffers that will be used to reconstruct the serialized data of a DDS sample from the different fragments. Each buffer hold one individual DDS sample and it has a size equal to the maximum serialized size of a DDS sample. The pool size can be configured using the QoS values **initial\_fragmented\_samples** and **max\_fragmented\_samples** in [48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QoSPolicy \(DDS Extension\) on page 876](#).

The main disadvantage in pre-allocating the serialization buffers is an increase in memory usage, especially when the maximum serialized of a DDS sample is quite large. *Connex* offers a setting that allows memory for a DDS sample to be allocated from the heap the first time a fragment is received. The amount of memory allocated equals the amount of memory needed to store all fragments in the DDS sample.

## 20.2.5 Reader-Side Memory Management when Working with Large Data

This section describes how to configure the *DataReader* side of the videoconferencing application introduced in [20.1.4 Writer-Side Memory Management when Working with Large Data on page 276](#) to optimize memory usage.

The following XML file can be used to optimize the memory usage in the previous example:

```
<?xml version="1.0"?>
<!-- XML QoS Profile for large data -->
<dds xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <!-- QoS Library containing the QoS profile used for large data -->
  <qos_library name="ReliableLargeDataLibrary">
    <!-- QoS profile used to optimize the memory usage in a
      DataWriter sending large data images
    -->
    <qos_profile name="ReliableLargeDataProfile"
      is_default_qos="true">
      <!-- QoS used to configure the DataWriter -->
      <datareader_qos>
        <history>
          <kind>KEEP_ALL_HISTORY_QOS</kind>
        </history>
        <resource_limits>
          <max_samples>32</max_samples>
          <!-- No need to pre-allocate 32 frames unless
            needed -->
          <initial_samples>1</initial_samples>
        </resource_limits>
      </qos_profile>
    </qos_library>
  </dds>
```

```

    <!-- Since the video frame samples have a
         large maximum serialized size we can configure
         the fragmented samples pool to use dynamic
         memory allocation. As an alternative,
         reduce max_fragmented_samples. However, that
         may cause fragment retransmission.
    -->
    <dynamically_allocate_fragmented_samples>
    1
    </dynamically_allocate_fragmented_samples>
  </reader_resource_limits>
  <property>
  <value>
    <!-- Java will use a buffer of 33KB to
         deserialize all frames with a
         serialized size smaller or equal than
         33KB. When an I-frame is received,
         Java will re-allocate the
         deserialization buffer to match the
         serialized size of the new frame.
    -->
    <element>
      <name>
dds.data_reader.history.memory_manager.java_stream.min_size
      </name>
      <value>33792</value>
    </element>
    <element>
      <name>
dds.data_reader.history.memory_manager.java_stream.trim_to_size
      </name>
      <value>1</value>
    </element>
  </value>
  </property>
</qos_profile>
</qos_library>
</dds>

```

To avoid preallocation of the samples in the *DataReader's* queue to their maximum size for Type-Plugin generated code in C, C++, Java, and .NET, replace the bounded sequence in *VideoFrame* with an unbounded sequence and generate code using the **-unboundedSupport** command-line option:

```

struct VideoFrame {
    boolean keyFrame;
    sequence<octet> data;
};

```

See [20.2.1 Memory Management for DataReaders Using Generated Type-Plugins on page 279](#) for more details.

To avoid preallocation of the samples in the *DataReader's* queue to their maximum size for *DynamicData*, set the **min\_size\_serialized** property to avoid the allocation of 1MB buffers for the *DataReader* queue samples (See [20.2.3 Memory Management for DynamicData DataReaders on page 280](#)).

## 20.3 Instance Memory Management for DataWriters

When an instance is registered with a *DataWriter*, the *DataWriter* serializes the key value and stores it with the instance.

Each instance maintained by the *DataWriter* has an associated buffer in which the *DataWriter* serializes the key. This buffer is either:

- Obtained from a pre-allocated pool (if the key's serialized size is  $\leq$  `dds.data_writer.history.memory_manager.fast_pool.pool_buffer_max_size`).
- Dynamically allocated from the heap (if the key's serialized size is  $>$  `dds.data_writer.history.memory_manager.fast_pool.pool_buffer_max_size`).

See [Table 20.5 Instance Memory Management Properties for DataWriters](#).

**Table 20.5 Instance Memory Management Properties for DataWriters**

Property	Description
<code>dds.data_writer.history.memory_manager.fast_pool.pool_buffer_max_size</code>	<p>Controls the memory allocation for the serialized key buffer that is stored with every instance.</p> <p>Default: -1 (UNLIMITED). All DDS sample buffers are obtained from the pre-allocated pool. The buffer size is the maximum serialized size of the DDS samples, as returned by the type plugin <code>get_serialized_sample_max_size()</code> operation.</p> <p>Notes:</p> <ul style="list-style-type: none"> <li>• If you use unbounded sequences or strings as part of your key, then you should set <code>pool_buffer_max_size</code> to a finite value. See <a href="#">17.1.1 Sequences on page 113</a>.</li> <li>• The <code>pool_buffer_max_size</code> also controls DDS sample memory management. See <a href="#">20.1 Sample Memory Management for DataWriters on page 271</a>.</li> </ul>

## 20.4 Instance Memory Management for DataReaders

There are a number of features that require *DataReaders* to allocate a buffer to store an intermediate, serialized representation of a sample. The size of these buffers is controlled with the property `dds.data_reader.history.memory_manager.fast_pool.pool_buffer_max_size`.

When a buffer is needed:

- If the required size is  $\leq$  `dds.data_reader.history.memory_manager.fast_pool.pool_buffer_max_size`, a preallocated buffer will be used. This buffer will not be freed until the *DataReader* is deleted and is therefore reused whenever a buffer is needed for a sample that matches this condition.
- If the required size is  $>$  `dds.data_reader.history.memory_manager.fast_pool.pool_buffer_max_size`, the buffer will be dynamically allocated from the heap and then freed once it is no longer needed.

This property must be set if you are using any of the following features:

- Keyed data types
- Query conditions (only required if also using `DynamicData`, or the Java, .NET, or Modern C++ language APIs)
- Data encryption using *RTI Security Plugins*
- User-data payload compression (see [47.3.2 Data Compression on page 782](#))

In the case of keyed data types, a buffer is used per-instance to store the serialized representation of the key value for that instance.

In the case of query conditions, when a query condition is created, all samples that are in the *DataReader's* queue need to be temporarily re-serialized in order to be evaluated against the query condition. A buffer that is allocated based on the value of this property is used for that serialization.

In the case of data encryption and compression, a buffer is needed when a sample is first received in order to decode or uncompress the sample into. If data encryption and compression are both being used, then two buffers will be allocated (because the sample must first be decoded into one buffer and then uncompressed into another buffer).

### Setting this property to a finite value

The key buffers, used to store the serialized key per-instance, come from a pre-allocated pool with **ResourceLimits::initial\_instances** initial buffers. Setting this property to a finite value will cause the buffers in the key buffer pool to be allocated to that size. If a larger buffer is needed when a new instance is received by the *DataReader*, a buffer of the correct size will be allocated at that time. If you use unbounded sequences or strings as part of your key, then you should set this property to a finite value. See [17.1.1 Sequences on page 113](#).

The buffers that are needed for samples are shared and are allocated once they are needed for the first time. When a buffer is needed, the required size will be checked against the value of this property. If the required size is less than or equal to this property's value and a buffer has not been allocated before, a buffer will be allocated with the property's size. This buffer will not be deallocated until the *DataReader* is deleted and will be reused every time a buffer with this size or smaller is needed. If a buffer is needed that is larger than the value configured by this property, it will be dynamically allocated to the correct size and then freed as soon as it is not needed anymore (once the sample has been deserialized). There will be at most two buffers allocated to the configured size. This will only happen if both data encryption and user-data payload compression are being used at the same time.

### Setting this property to unlimited (DEFAULT)

If this property is set to -1 (UNLIMITED), the size of the key buffers is the maximum serialized size of the key as returned by the type plugin `get_serialized_key_max_size()` operation. These buffers still come from a pre-allocated pool. The size of the buffers used for samples will be allocated, when

needed, to the maximum serialized size of a sample as returned by the type plugin **get\_serialized\_sample\_max\_size()** operation. They are not deallocated until the *DataReader* is deleted so that they can be reused whenever needed.

# Chapter 21 Mechanisms for Achieving Information Durability and Persistence

## 21.1 Overview

Durable Writer History and Durable Reader State are temporarily disabled. A future feature release will resume support for them. Use [Part 12: RTI Persistence Service on page 1205](#) to persist your data instead. For further clarification, see the [RTI Connex Core Libraries What's New in 7.0.0](#) or contact RTI Support at [support@rti.com](mailto:support@rti.com).

*Connex* offers the following mechanisms for achieving durability and persistence:

- **Durable Writer History** This feature allows a *DataWriter* to persist its historical cache, perhaps locally, so that it can survive shutdowns, crashes and restarts. When an application restarts, each *DataWriter* that has been configured to have durable writer history automatically loads all of the data in this cache from disk and can carry on sending data as if it had never stopped executing. To the rest of the system, it will appear as if the *DataWriter* had been temporarily disconnected from the network and then reappeared.
- **Durable Reader State** This feature allows a *DataReader* to persist its state and remember which data it has already received. When an application restarts, each *DataReader* that has been configured to have durable reader state automatically loads its state from disk and can carry on receiving data as if it had never stopped executing. Data that had already been received by the *DataReader* before the restart will be suppressed so that it is not even sent over the network.
- **Data Durability** This feature is a full implementation of the OMG DDS Persistence Profile. The [47.9 DURABILITY QosPolicy on page 809](#) allows an application to configure a *DataWriter* so that the information written by the *DataWriter* survives beyond the lifetime of the *DataWriter*. In this manner, a late-joining *DataReader* can subscribe to and

receive the information even after the *DataWriter* application is no longer executing. To use this feature, you need *Persistence Service*, a separate application described in [Introduction to RTI Persistence Service \(Chapter 73 on page 1206\)](#).

These features can be configured separately or in combination. To use Durable Writer State and Durable Reader State, you need a relational database, which is not included with *Connex*. *Persistence Service* does not require a database when used in TRANSIENT mode (see [21.5.1 RTI Persistence Service on page 305](#)) or in PERSISTENT mode with file-system storage (see [21.5.1 RTI Persistence Service on page 305](#) and [74.5 Configuring Remote Administration on page 1215](#)).

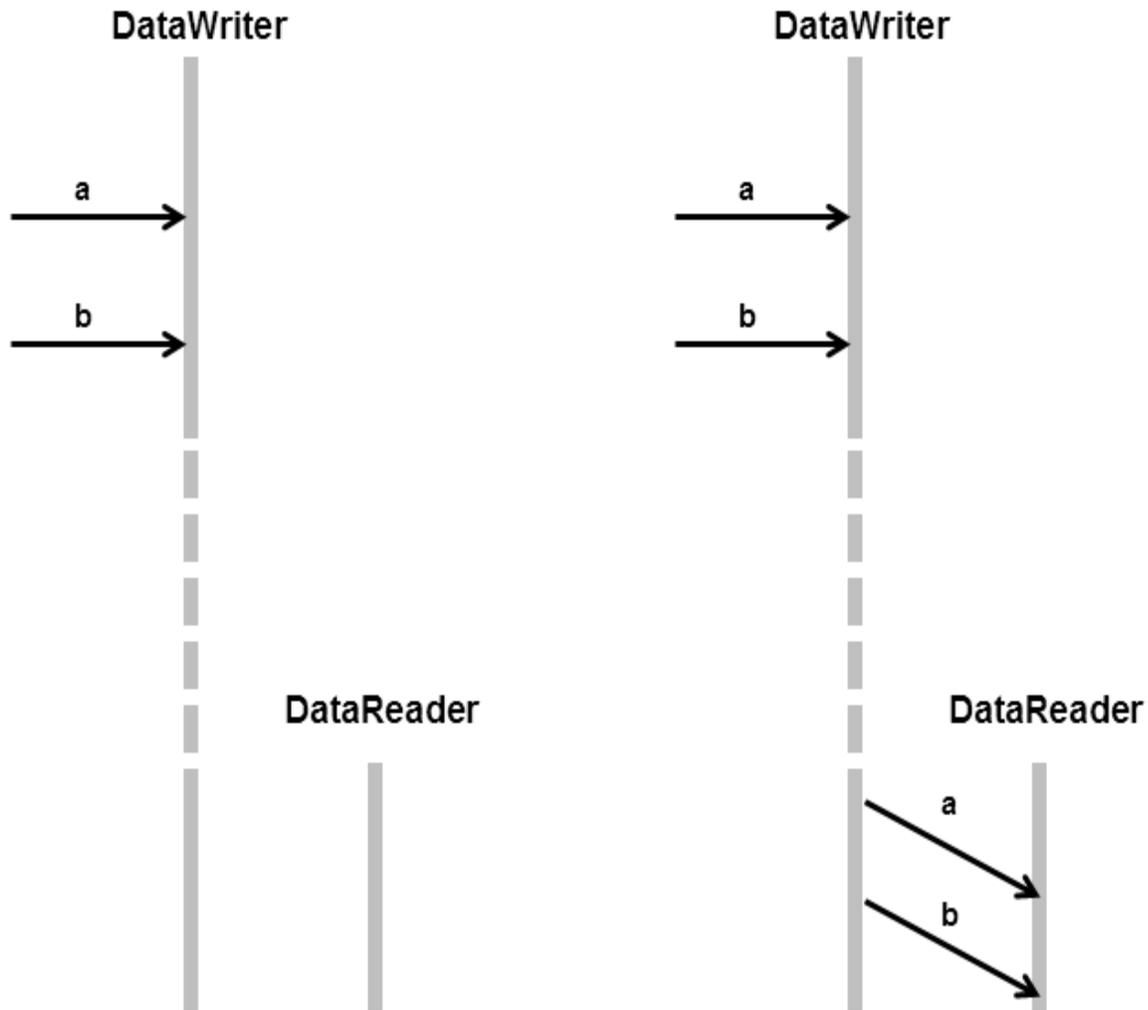

To understand how these features interact we will examine the behavior of the system using the following scenarios:

- [21.1.1 Scenario 1. DataReader Joins after DataWriter Restarts \(Durable Writer History\) below](#)
- [21.1.2 Scenario 2: DataReader Restarts While DataWriter Stays Up \(Durable Reader State\) on page 291](#)
- [21.1.3 Scenario 3. DataReader Joins after DataWriter Leaves Domain \(Durable Data\) on page 292](#)

#### **21.1.1 Scenario 1. DataReader Joins after DataWriter Restarts (Durable Writer History)**

In this scenario, a *DomainParticipant* joins the domain, creates a *DataWriter* and writes some data, then the *DataWriter* shuts down (gracefully or due to a fault). The *DataWriter* restarts and a *DataReader* joins the domain. Depending on whether the *DataWriter* is configured with durable history, the late-joining *DataReader* may or may not receive the data published already by the *DataWriter* before it restarted. This is illustrated in [Figure 21.1: Durable Writer History on the next page](#). For more information, see [21.3 Durable Writer History on page 295](#).

Figure 21.1: Durable Writer History

*Without Durable Writer History:*  
the late-joining DataReader will not receive data (a and b) that was published before the DataWriter's restart.

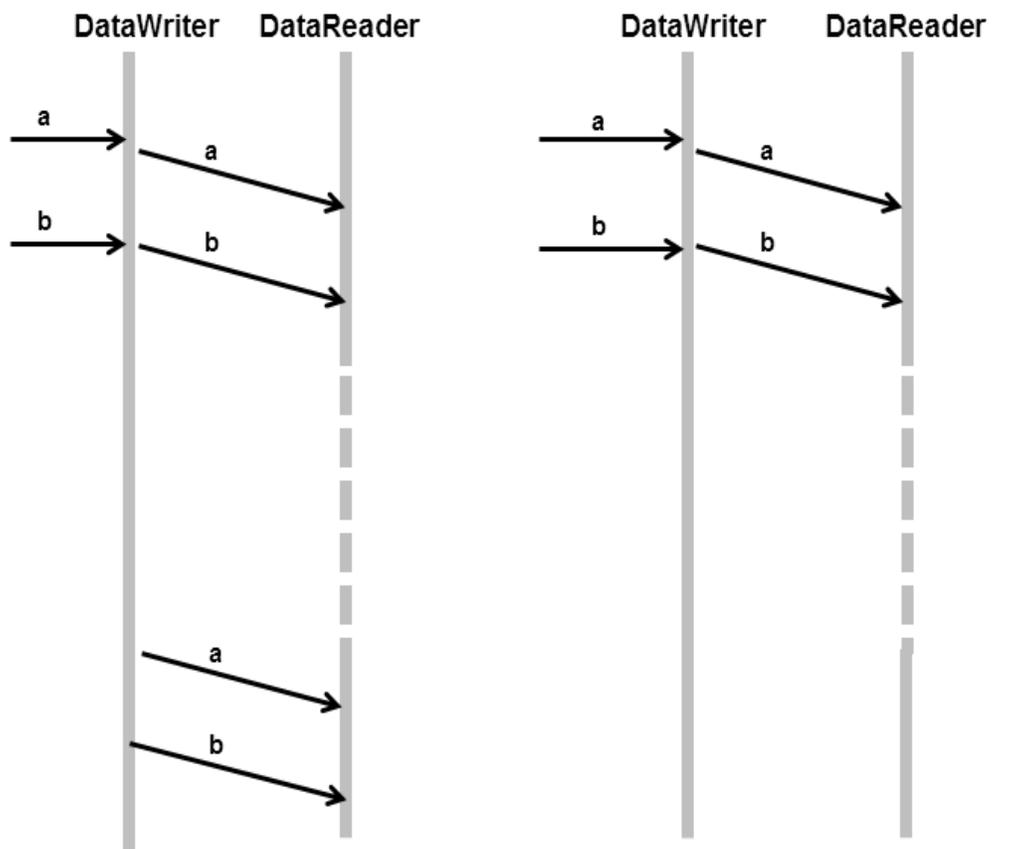

*With Durable Writer History:*  
the restarted DataWriter will recover its history and deliver its data to the late-joining DataReader

## 21.1.2 Scenario 2: DataReader Restarts While DataWriter Stays Up (Durable Reader State)

In this scenario, two *DomainParticipants* join a domain; one creates a *DataWriter* and the other a *DataReader* on the same Topic. The *DataWriter* publishes some data ("a" and "b") that is received by the *DataReader*. After this, the *DataReader* shuts down (gracefully or due to a fault) and then restarts—all while the *DataWriter* remains present in the domain.

Depending on whether the *DataReader* is configured with Durable Reader State, the *DataReader* may or may not receive a duplicate copy of the data it received before it restarted. This is illustrated in [Figure 21.2: Durable Reader State](#) below. For more information, see [21.4 Durable Reader State](#) on page 299.

Figure 21.2: Durable Reader State

*Without Durable Reader State:*  
the DataReader will receive the data that was already received before the restart.

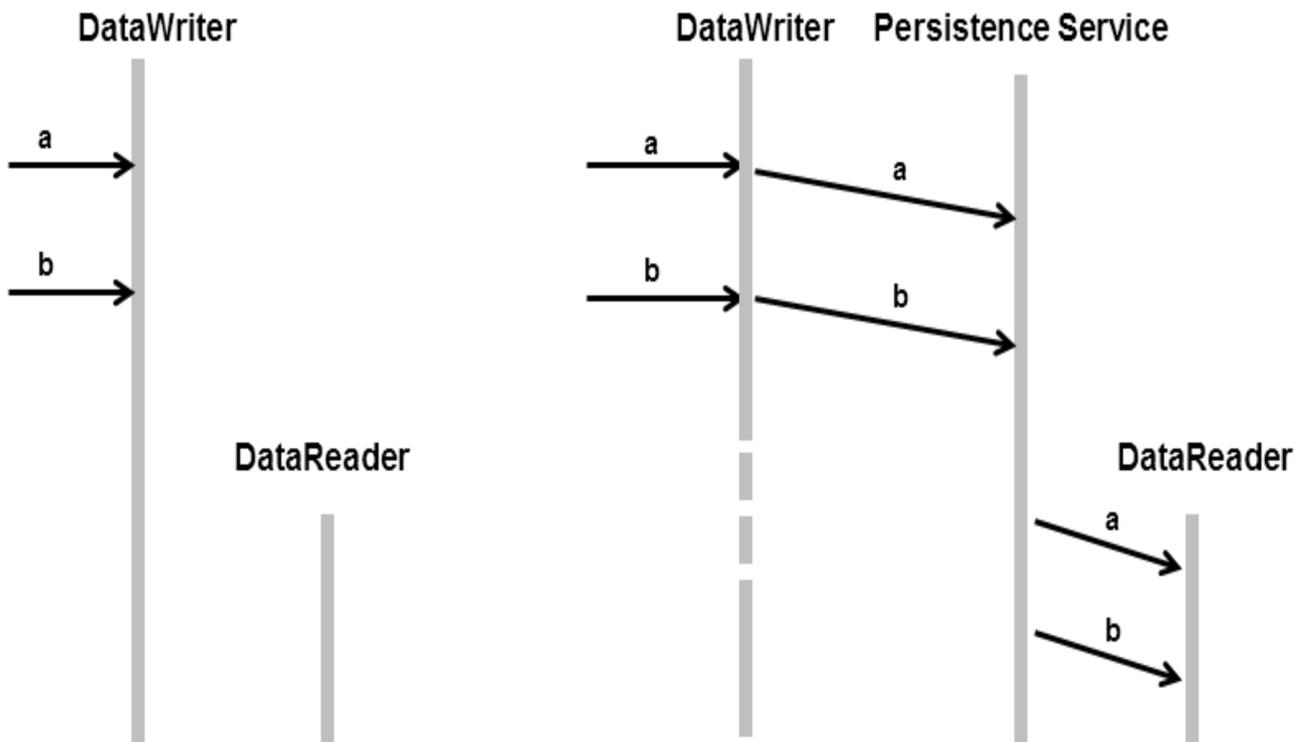

*With Durable Reader State:*  
the DataReader remembers that it already received the data and does not request it again.

### 21.1.3 Scenario 3. DataReader Joins after DataWriter Leaves Domain (Durable Data)

In this scenario, a *DomainParticipant* joins a domain, creates a *DataWriter*, publishes some data on a Topic and then shuts down (gracefully or due to a fault). Later, a *DataReader* joins the domain and subscribes to the data. *Persistence Service* is running.

Depending on whether Durable Data is enabled for the Topic, the *DataReader* may or may not receive the data previous published by the *DataWriter*. This is illustrated in [Figure 21.3: Durable Data on the next page](#). For more information, see [21.5 Data Durability on page 304](#)

Figure 21.3: Durable Data

Without Durable Data:  
the late-joining DataReader  
will not receive data (a and b)  
that was published before the  
DataWriter quit.

With Durable Data:  
Persistence Service  
remembers what data was  
published and delivers it to  
the late-joining DataReader.

This third scenario is similar to [21.1.1 Scenario 1. DataReader Joins after DataWriter Restarts \(Durable Writer History\)](#) on [page 289](#) except that in this case the *DataWriter* does not need to restart for the *DataReader* to get the data previously written by the *DataWriter*. This is because *Persistence Service* acts as an intermediary that stores the data so it can be given to late-joining *DataReaders*.

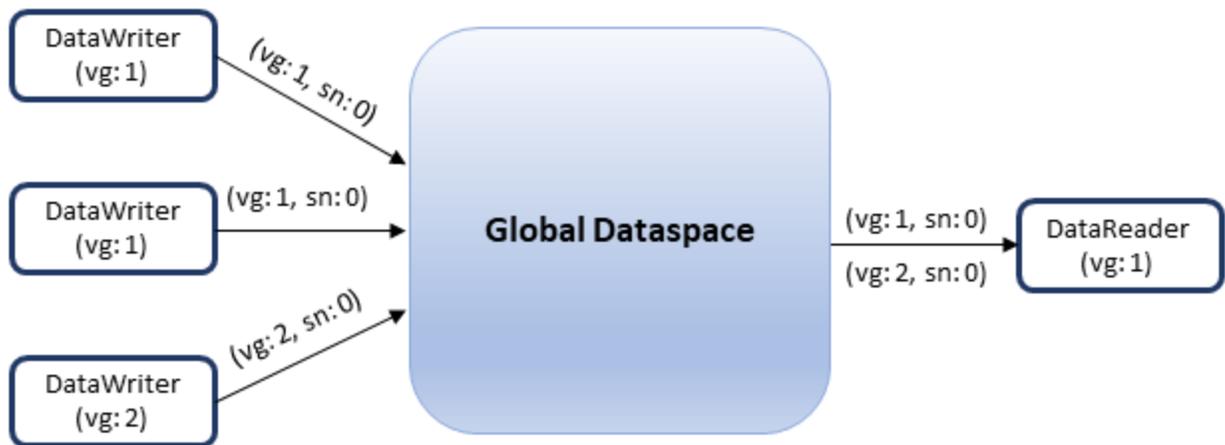

## 21.2 Durability and Persistence Based on Virtual GUIDs

Every modification to the global dataspace made by a *DataWriter* is identified by a pair (virtual GUID, sequence number).

- The virtual GUID (Global Unique Identifier) is a 16-byte character identifier associated with a *DataWriter* or *DataReader*; it is used to uniquely identify this entity in the global data space.
- The sequence number is a 64-bit identifier that identifies changes published by a specific *DataWriter*.

Several *DataWriters* can be configured with the same virtual GUID. If each of these *DataWriters* publishes a sample with sequence number '0', the sample will only be received once by the *DataReaders* subscribing to the content published by the *DataWriters* (see [Figure 21.4: Global Dataspace Changes below](#)).

Figure 21.4: Global Dataspace Changes

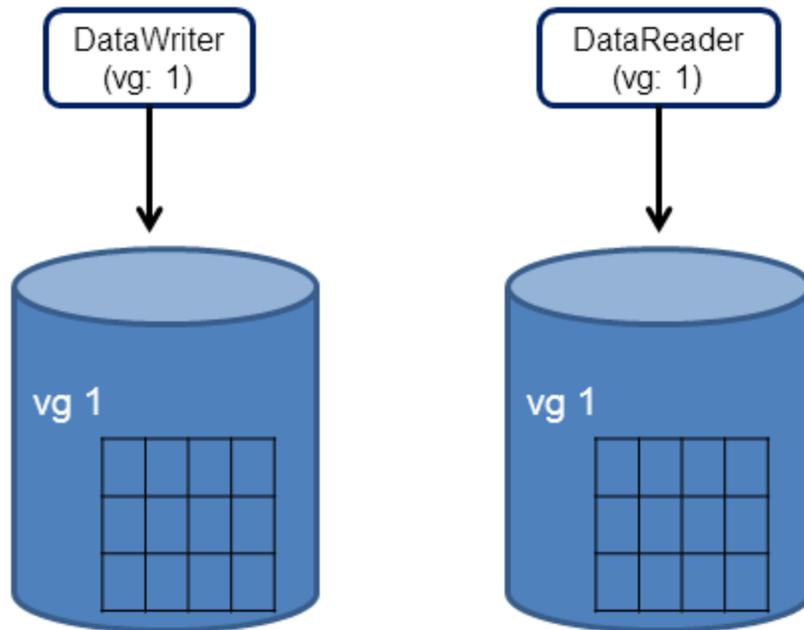

Additionally, *Connex* uses the virtual GUID to associate a persisted state (state in permanent storage) to the corresponding *Entity*.

For example, the history of a *DataWriter* will be persisted in a database table with a name generated from the virtual GUID of the *DataWriter*. If the *DataWriter* is restarted, it must have associated the same virtual GUID to restore its previous history.

Likewise, the state of a *DataReader* will be persisted in a database table whose name is generated from the *DataReader* virtual GUID (see [Figure 21.5: History/State Persistence Based on Virtual GUID on the next page](#)).

Figure 21.5: History/State Persistence Based on Virtual GUID

- A *DataWriter*'s virtual GUID can be configured using the member **virtual\_guid** in the [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\)](#) on page 788.
- A *DataReader*'s virtual GUID can be configured using the member **virtual\_guid** in the [48.1 DATA\\_READER\\_PROTOCOL QosPolicy \(DDS Extension\)](#) on page 871.

The `DDS_PublicationBuiltinTopicData` and `DDS_SubscriptionBuiltinTopicData` structures include the virtual GUID associated with the discovered publication or subscription (see [28.2 Built-in DataReaders](#) on page 360).

## 21.3 Durable Writer History

The [47.9 DURABILITY QosPolicy](#) on page 809 controls whether or not, and how, published samples are stored by the *DataWriter* application for *DataReaders* that are found after the samples were initially written. The samples stored by the *DataWriter* constitute the *DataWriter*'s history.

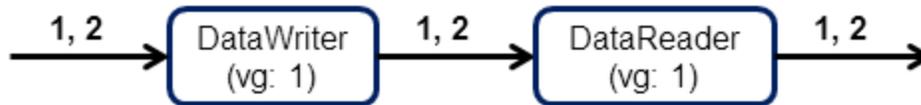

*Connex* provides the capability to make the *DataWriter* history durable, by persisting its content in a relational database. This makes it possible for the history to be restored when the *DataWriter* restarts.

The association between the history stored in the database and the *DataWriter* is done using the virtual GUID.

## 21.3.1 Durable Writer History Use Case

The following use case describes the durable writer history functionality:

1. A *DataReader* receives two samples with sequence number 1 and 2 published by a *DataWriter* with virtual GUID 1.

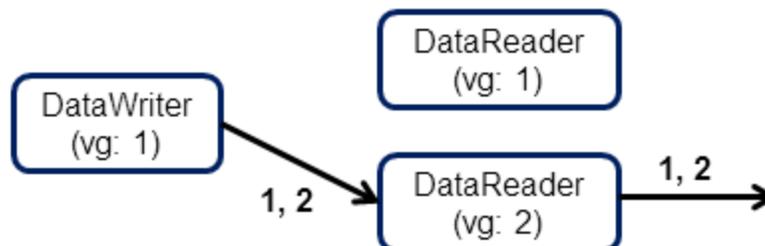

2. The process running the *DataWriter* is stopped and a new late-joining *DataReader* is created.

The new *DataReader* with virtual GUID 2 does not receive samples 1 and 2 because the original *DataWriter* has been destroyed. If the samples must be available to late-joining *DataReaders* after the *DataWriter* deletion, you can use *Persistence Service*, described in [Introduction to RTI Persistence Service \(Chapter 73 on page 1206\)](#).

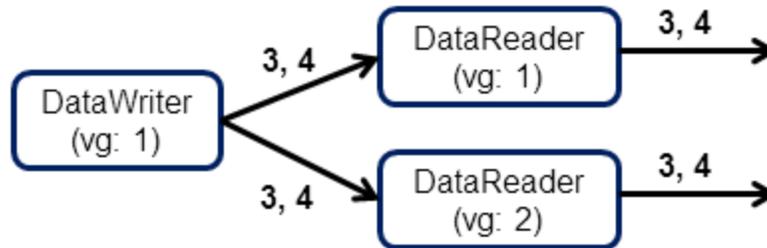

3. The *DataWriter* is restarted using the same virtual GUID.

After being restarted, the *DataWriter* restores its history. The late-joining *DataReader* will receive samples 1 and 2 because they were not received previously. The *DataReader* with virtual GUID 1 will not receive samples 1 and 2 because it already received them

4. The *DataWriter* publishes two new samples.

The two new samples with sequence numbers 3 and 4 will be received by both *DataReaders*.

## 21.3.2 How To Configure Durable Writer History

*Connex* allows a *DataWriter*'s history to be stored in a relational database that provides an ODBC driver.

For each *DataWriter* history that is configured to be durable, *Connex* will create a maximum of two tables:

- The first table is used to store the samples associated with the writer history. The name of that table is WS<32 uuencoding of the writer virtual GUID>.
- The second table is only created for keyed-topic and it is used to store the instances associated with the writer history. The name of the second table is WI<32 uuencoding of the writer virtual GUID>.

To configure durable writer history, use the [47.19 PROPERTY QosPolicy \(DDS Extension\) on page 837](#) associated with *DataWriters* and *DomainParticipants*.

A 'durable writer history' property defined in the *DomainParticipant* will be applicable to all the *DataWriters* belonging to the *DomainParticipant* unless it is overwritten by the *DataWriter*. [Table 21.1 Durable Writer History Properties](#) lists the supported 'durable writer history' properties.

**Table 21.1 Durable Writer History Properties**

Property	Description
dds.data_writer.history.plugin_name	<b>Required.</b> Must be set to "dds.data_writer.history.odbc_plugin.builtin" to enable durable writer history in the <i>DataWriter</i> .
dds.data_writer.history.odbc_plugin.dsn	<b>Required.</b> The ODBC DSN (Data Source Name) associated with the database where the writer history must be persisted.

Table 21.1 Durable Writer History Properties

Property	Description
dds.data_writer.history.odbc_plugin.driver	Tells <i>Connex</i> which ODBC driver to load. If the property is not specified, <i>Connex</i> will try to use the standard ODBC driver manager library (UnixOdbc on Linux systems, the Windows ODBC driver manager on Windows systems).
dds.data_writer.history.odbc_plugin.username	Configures the username/password used to connect to the database.
dds.data_writer.history.odbc_plugin.password	Default: No password or username
dds.data_writer.history.odbc_plugin.shared	When set to 1, <i>Connex</i> will create a single connection per DSN that will be shared across <i>DataWriters</i> within the same <i>Publisher</i> . A <i>DataWriter</i> can be configured to create its own database connection by setting this property to 0 (the default).
dds.data_writer.history.odbc_plugin.instance_cache_max_size	These properties configure the resource limits associated with the ODBC writer history caches. To minimize the number of accesses to the database, <i>Connex</i> uses two caches, one for samples and one for instances. The initial size and the maximum size of these caches are configured using these properties.
dds.data_writer.history.odbc_plugin.instance_cache_init_size	The resource limits, <b>initial_instances</b> , <b>max_instances</b> , <b>initial_samples</b> , <b>max_samples</b> , and <b>max_samples_per_instance</b> defined in <a href="#">47.22 RESOURCE_LIMITS QosPolicy on page 850</a> are used to configure the maximum number of samples and instances that can be stored in the relational database. Defaults:
dds.data_writer.history.odbc_plugin.sample_cache_max_size	<b>instance_cache_max_size</b> : <b>max_instances</b> in <a href="#">47.22 RESOURCE_LIMITS QosPolicy on page 850</a>
dds.data_writer.history.odbc_plugin.sample_cache_init_size	<b>instance_cache_init_size</b> : <b>initial_instances</b> in <a href="#">47.22 RESOURCE_LIMITS QosPolicy on page 850</a> <b>sample_cache_max_size</b> : 32 <b>sample_cache_init_size</b> : 32
dds.data_writer.history.odbc_plugin.sample_cache_init_size	If <b>in_memory_state</b> (see below in this table) is 1, <b>instance_cache_max_size</b> is always equal to <b>max_instances</b> in <a href="#">47.22 RESOURCE_LIMITS QosPolicy on page 850</a> —it cannot be changed.
dds.data_writer.history.odbc_plugin.restore	This property indicates whether or not the persisted writer history must be restored once the <i>DataWriter</i> is restarted. If this property is 0, the content of the database associated with the <i>DataWriter</i> being restarted will be deleted. If it is 1, the <i>DataWriter</i> will restore its previous state from the database content. Default: 1
dds.data_writer.history.odbc_plugin.in_memory_state	This property determines how much state will be kept in memory by the ODBC writer history in order to avoid accessing the database. If this property is 1, then the property <b>instance_cache_max_size</b> (see above in this table) is always equal to <b>max_instances</b> in <a href="#">47.22 RESOURCE_LIMITS QosPolicy on page 850</a> —it cannot be changed. In addition, the ODBC writer history will keep in memory a fixed state overhead of 24 bytes per sample. This mode provides the best ODBC writer history performance. However, the restore operation will be slower and the maximum number of samples that the writer history can manage is limited by the available physical memory. If it is 0, all the state will be kept in the underlying database. In this mode, the maximum number of samples in the writer history is not limited by the physical memory available. Default: 1

Durable Writer History is not supported for Multi-channel *DataWriters* (see [Multi-Channel DataWriters for High-Performance Filtering \(Chapter 36 on page 576\)](#)) or when Batching is enabled (see [47.2 BATCH QoS Policy \(DDS Extension\) on page 773](#)); an error is reported if this type of *DataWriter* tries to configure Durable Writer History.

See also: [21.4 Durable Reader State below](#).

### Example C++ Code

```

/* Get default QoS */
...
retcode = DDSPropertyQoSPolicyHelper::add_property (writerQos.property,
    "dds.data_writer.history.plugin_name",
    "dds.data_writer.history.odbc_plugin.builtin",
    DDS_BOOLEAN_FALSE);
if (retcode != DDS_RETCODE_OK) {
    /* Report error */
}
retcode = DDSPropertyQoSPolicyHelper::add_property (writerQos.property,
    "dds.data_writer.history.odbc_plugin.dsn",
    "<user DSN>",
    DDS_BOOLEAN_FALSE);
if (retcode != DDS_RETCODE_OK) {
    /* Report error */
}
retcode = DDSPropertyQoSPolicyHelper::add_property (writerQos.property,
    "dds.data_writer.history.odbc_plugin.driver",
    "<ODBC library>",
    DDS_BOOLEAN_FALSE);
if (retcode != DDS_RETCODE_OK) {
    /* Report error */
}
retcode = DDSPropertyQoSPolicyHelper::add_property (writerQos.property,
    "dds.data_writer.history.odbc_plugin.shared",
    "<0|1>",
    DDS_BOOLEAN_FALSE);
if (retcode != DDS_RETCODE_OK) {
    /* Report error */
}
/* Create Data Writer */
...

```

## 21.4 Durable Reader State

*Durable reader state* allows a *DataReader* to locally store its state in disk and remember the data that has already been processed by the application<sup>1</sup>. When an application restarts, each *DataReader* configured to have durable reader state automatically reads its state from disk. Data that has already been processed by the application before the restart will not be provided to the application again.

<sup>1</sup>The circumstances under which a data sample is considered “processed by the application” are described in the sections that follow.

**Important:** The *DataReader* does not persist the full contents of the data in its historical cache; it only persists an identification (e.g. sequence numbers) of the data the application has processed. This distinction is not meaningful if your application always uses the ‘take’ methods to access your data, since these methods remove the data from the cache at the same time they deliver it to your application. (See [41.3.1 Read vs. Take on page 666](#)) However, if your application uses the ‘read’ methods, leaving the data in the *DataReader's* cache after you've accessed it for the first time, those previously viewed samples will not be restored to the *DataReader's* cache in the event of a restart.

*Connex* requires a relational database to persist the state of a *DataReader*. This database is accessed using ODBC.

## 21.4.1 Durable Reader State With Protocol Acknowledgment

For each *DataReader* configured to have durable state, *Connex* will create one database table with the following naming convention: **RS<32 uuencoding of the reader virtual GUID>**. This table will store the last sequence number processed from each virtual *GUID*. For *DataReaders* on keyed topics requesting instance-ordering (see [46.6 PRESENTATION QosPolicy on page 760](#)), this state will be stored per instance per virtual *GUID*.

### Criteria to consider a sample “processed by the application”

- For the read/take methods that require calling **return\_loan()**, a sample 's1' with sequence number 's1\_seq\_num' and virtual GUID 'vg1' is considered processed by the application when the *DataReader's* **return\_loan()** operation is called for sample 's1' or any other sample with the same virtual GUID and a sequence number greater than 's1\_seq\_num'. For example:

```
retcode = Foo_reader->take(data_seq, info_seq,
    DDS_LENGTH_UNLIMITED, DDS_ANY_SAMPLE_STATE,
    DDS_ANY_VIEW_STATE, DDS_ANY_INSTANCE_STATE);
if (retcode == DDS_RETCODE_NO_DATA) {
    return;
} else if (retcode != DDS_RETCODE_OK) {
    /* report error */
    return;
}
for (i = 0; i < data_seq.length(); ++i) {
    /* Operate with the data */
}
/* Return the loan */
retcode = Foo_reader->return_loan(data_seq, info_seq);
if (retcode != DDS_RETCODE_OK) {
    /* Report and error */
}
/* At this point the samples contained in data_seq
will be considered as received. If the DataReader
restarts, the samples will not be received again */
```

- For the read/take methods that do not require calling `return_loan()`, a sample 's1' with sequence number 's1\_seq\_num' and virtual GUID 'vg1' will be considered processed after the application reads or takes the sample 's1' or any other sample with the same virtual GUID *and* with a sequence number greater than 's1\_seq\_num'. For example:

```
retcode = Foo_reader->take_next_sample(data,info);
/* At this point the sample contained in data will be
   considered as received. All the samples with a sequence
   number smaller than the sequence number associated with
   data will also be considered as received.
   If the DataReader restarts, these sample will not
   be received again */
```

If you access the samples in the *DataReader* cache out of order—for example via *QueryCondition*, specifying an instance state, or reading by instance when the PRESENTATION QoS is not set to INSTANCE\_PRESENTATION\_QOS—then the samples that have not yet been taken or read by the application may still be considered as "processed by the application".

### 21.4.1.1 Bandwidth Utilization

To optimize network usage, if a *DataReader* configured with durable reader state is restarted and it discovers a *DataWriter* with a virtual GUID 'vg', the *DataReader* will ACK all the samples with a sequence number smaller than 'sn', where 'sn' is the first sequence number that has not been being processed by the application for 'vg'.

Notice that the previous algorithm can significantly reduce the number of duplicates on the wire. However, it does not suppress them completely in the case of keyed *DataReaders* where the durable state is kept per (instance, virtual GUID). In this case, and assuming that the application has read samples out of order (e.g., by reading different instances), the ACK is sent for the lowest sequence number processed across all instances and may cause samples already processed to flow on the network again. These redundant samples waste bandwidth, but they will be dropped by the *DataReader* and not be delivered to the application.

## 21.4.2 Durable Reader State with Application Acknowledgment

This section assumes you are familiar with the concept of *Application Acknowledgment* as described in [31.12 Application Acknowledgment on page 418](#).

For each *DataReader* configured to be durable and that uses application acknowledgement (see [31.12 Application Acknowledgment on page 418](#)), *Connex* will create one database table with the following naming convention: **RS<32 uuencoding of the reader virtual GUID>**. This table will store the list of sequence number *intervals* that have been acknowledged for each virtual GUID. The size of the column that stores the sequence number intervals is limited to 32767 bytes. If this size is exceeded for a given virtual GUID, the operation that persists the *DataReader* state into the database will fail.

### 21.4.2.1 Bandwidth Utilization

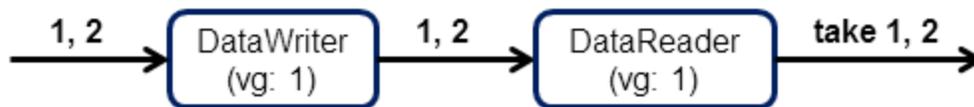

To optimize network usage, if a *DataReader* configured with durable reader state is restarted and it discovers a *DataWriter* with a virtual GUID 'vg', the *DataReader* will send an APP\_ACK message with all the samples that were auto-acknowledged or explicitly acknowledged in previous executions.

Notice that this algorithm can significantly reduce the number of duplicates on the wire. However, it does not suppress them completely since the *DataReader* may send a NACK and receive some samples from the *DataWriter* before the *DataWriter* receives the APP\_ACK message.

### 21.4.3 Durable Reader State Use Case

The following use case describes the durable reader state functionality:

1. A *DataReader* receives two samples with sequence number 1 and 2 published by a *DataWriter* with virtual GUID 1. The application takes those samples.

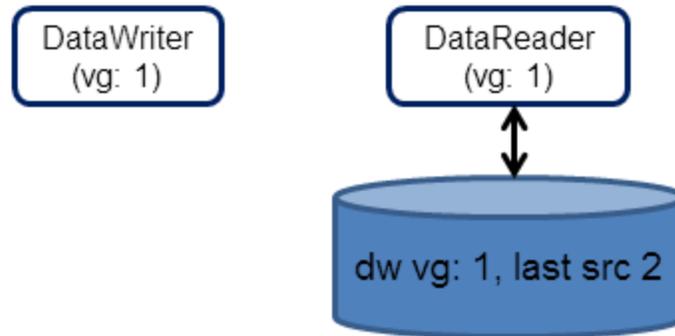

2. After the application returns the loan on samples 1 and 2, the *DataReader* considers them as processed and it persists the state change.

3. The process running the *DataReader* is stopped.

4. The *DataReader* is restarted.

Because all the samples with sequence number smaller or equal than 2 were considered received, the reader will not ask for these samples from the *DataWriter*.

## 21.4.4 How To Configure a DataReader for Durable Reader State

To configure a *DataReader* with durable reader state, use the [47.19 PROPERTY QosPolicy \(DDS Extension\)](#) on page 837 associated with *DataReaders* and *DomainParticipants*.

A property defined in the *DomainParticipant* will be applicable to all the *DataReaders* contained in the participant unless it is overwritten by the *DataReaders*. [Table 21.2 Durable Reader State Properties](#) lists the supported properties.

**Table 21.2 Durable Reader State Properties**

Property	Description
dds.data_reader.state.odbc.dsn	<b>Required.</b> The ODBC DSN (Data Source Name) associated with the database where the <i>DataReader</i> state must be persisted.
dds.data_reader.state.filter_redundant_samples	To enable durable reader state, this property must be set to 1. When set to 0, the reader state is not maintained and <i>Connex</i> does not filter duplicate samples that may be coming from the same virtual writer. Default: 1
dds.data_reader.state.odbc.driver	This property indicates which ODBC driver to load. If the property is not specified, <i>Connex</i> will try to use the standard ODBC driver manager library (UnixOdbc on Linux systems, the Windows ODBC driver manager on Windows systems).
dds.data_reader.state.odbc.username	These two properties configure the username and password used to connect to the database. Default: No password or username
dds.data_reader.state.odbc.password	

Table 21.2 Durable Reader State Properties

Property	Description
dds.data_reader.state.restore	This property indicates if the persisted <i>DataReader</i> state must be restored or not once the <i>DataReader</i> is restarted. If this property is 0, the previous state will be deleted from the database. If it is 1, the <i>DataReader</i> will restore its previous state from the database content. Default: 1
dds.data_reader.state.checkpoint_frequency	This property controls how often the reader state is stored into the database. A value of <i>N</i> means store the state once every <i>N</i> samples. A high frequency will provide better performance. However, if the reader is restarted it may receive some duplicate samples. These samples will be filtered by <i>Connex</i> and they will not be propagated to the application. Default: 1
dds.data_reader.state.persistence_service.request_depth	This property indicates how many of the most recent historical samples the persisted <i>DataReader</i> wants to receive upon start-up. Default: 0

**Example (C++ code):**

```

/* Get default QoS */
...
retcode = DDSPropertyQosPolicyHelper::add_property(
    readerQos.property,
    "dds.data_reader.state.odbc.dsn",
    "<user DSN>", DDS_BOOLEAN_FALSE);

if (retcode != DDS_RETCODE_OK) {
    /* Report error */
}

retcode = DDSPropertyQosPolicyHelper::add_property(readerQos.property,
    "dds.data_reader.state.odbc.driver",
    "<ODBC library>", DDS_BOOLEAN_FALSE);
if (retcode != DDS_RETCODE_OK) {
    /* Report error */
}

retcode = DDSPropertyQosPolicyHelper::add_property(readerQos.property,
    "dds.data_reader.state.restore", "<0|1>",
    DDS_BOOLEAN_FALSE);
if (retcode != DDS_RETCODE_OK) {
    /* Report error */
}
/* Create Data Reader */
...

```

## 21.5 Data Durability

The data durability feature is an implementation of the OMG DDS Persistence Profile. The [47.9 DURABILITY QosPolicy on page 809](#) allows an application to configure a *DataWriter* so that the information written by the *DataWriter* survives beyond the lifetime of the *DataWriter*.

*Connex* implements TRANSIENT and PERSISTENT durability using an external service called *RTI Persistence Service*, available for purchase as a separate RTI product.

*Persistence Service* receives information from *DataWriters* configured with TRANSIENT or PERSISTENT durability and makes that information available to late-joining *DataReaders*—even if the original *DataWriter* is not running.

The samples published by a *DataWriter* can be made durable by setting the **kind** field of the [47.9 DURABILITY QosPolicy on page 809](#) to one of the following values:

- **DDS\_TRANSIENT\_DURABILITY\_QOS**: *Connex* will store previously published samples in memory using *Persistence Service*, which will send the stored data to newly discovered *DataReaders*.
- **DDS\_PERSISTENT\_DURABILITY\_QOS**: *Connex* will store previously published samples in permanent storage, like a disk, using *Persistence Service*, which will send the stored data to newly discovered *DataReaders*.

A *DataReader* can request TRANSIENT or PERSISTENT data by setting the **kind** field of the corresponding [47.9 DURABILITY QosPolicy on page 809](#). A *DataReader* requesting PERSISTENT data will not receive data from *DataWriters* or *Persistence Service* applications that are configured with TRANSIENT durability.

## 21.5.1 RTI Persistence Service

*Persistence Service* is a *Connex* application that is configured to persist topic data. For each one of the topics that must be persisted for a specific domain, the service will create a *DataWriter* (known as PRSTDataWriter) and a *DataReader* (known as PRSTDataReader). The samples received by the PRSTDataReaders will be published by the corresponding PRSTDataWriters to be available for late-joining *DataReaders*.

For more information on *Persistence Service*, please see:

- [Introduction to RTI Persistence Service \(Chapter 73 on page 1206\)](#)
- [Configuring Persistence Service \(Chapter 74 on page 1207\)](#)
- [Running RTI Persistence Service \(Chapter 75 on page 1233\)](#)

*Persistence Service* can be configured to operate in PERSISTENT or TRANSIENT mode:

- **TRANSIENT mode** The PRSTDataReaders and PRSTDataWriters will be created with TRANSIENT durability and *Persistence Service* will keep the received samples in memory. Samples published by a TRANSIENT *DataWriter* will survive the *DataWriter* lifecycle but will

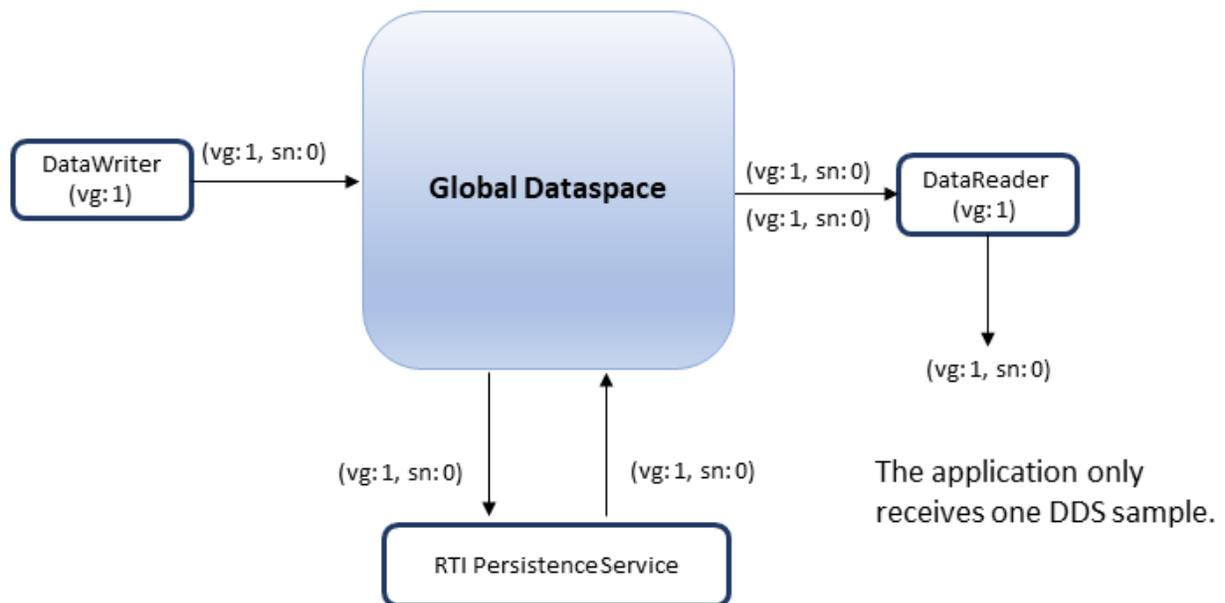

not survive the lifecycle of *Persistence Service* (unless you are running multiple copies).

- **PERSISTENT mode** The PRSTDataWriters and PRSTDataReaders will be created with PERSISTENT durability and *Persistence Service* will store the received samples in files. Samples published by a PERSISTENT *DataWriter* will survive the *DataWriter* lifecycle as well as any restarts of *Persistence Service*.

### Peer-to-Peer Communication:

By default, a PERSISTENT/TRANSIENT *DataReader* will receive samples directly from the original *DataWriter* if it is still alive. In this scenario, the *DataReader* may also receive the same samples from *Persistence Service*. Duplicates will be discarded at the middleware level. This Peer-To-Peer communication pattern is illustrated in [Figure 21.6: Peer-to-Peer Communication](#) below. To use this peer-to-peer communication pattern, set the **direct\_communication** field in the [47.9 DURABILITY QosPolicy on page 809](#) to TRUE. A PERSISTENT/TRANSIENT *DataReader* will receive information directly from PERSISTENT/TRANSIENT *DataWriters*.

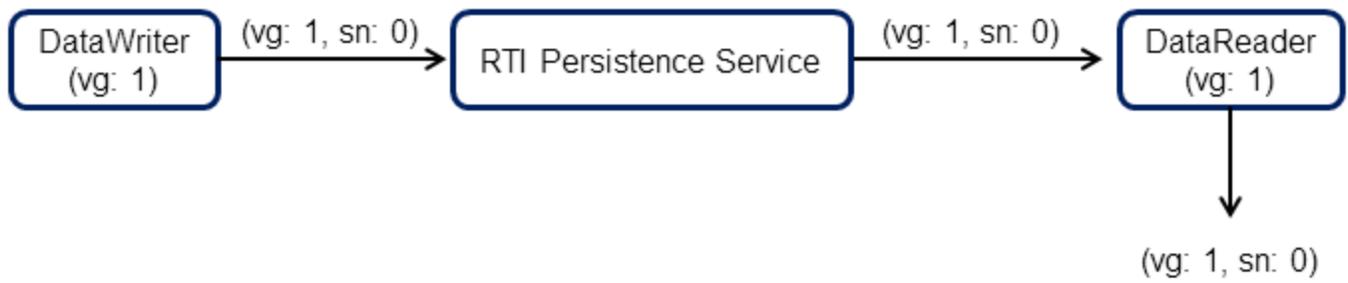

Figure 21.6: Peer-to-Peer Communication

### Relay Communication

A PERSISTENT/TRANSIENT *DataReader* may also be configured to not receive samples from the original *DataWriter*. In this case the traffic is relayed by *Persistence Service*. This ‘relay communication’ pattern is illustrated in [Figure 21.7: Relay Communication on the next page](#). To use relay communication, set the **direct\_communication** field in the [47.9 DURABILITY QosPolicy on page 809](#) to FALSE. A PERSISTENT/TRANSIENT *DataReader* will receive all the information from *Persistence Service*.

Figure 21.7: Relay Communication

# Part 4: Getting Applications to Discover Each Other

This section includes:

- [Discovery Overview \(Chapter 22 on page 309\)](#)
- [Ports Used for Discovery \(Chapter 23 on page 319\)](#)
- [Configuring the Peers List Used in Discovery \(Chapter 24 on page 324\)](#)
- [Discovery: Under the Hood \(Chapter 25 on page 331\)](#)
- [Discovered RTPS Locators and Changes with IP Mobility \(Chapter 26 on page 348\)](#)
- [Restricting Communication—Ignoring Entities \(Chapter 27 on page 352\)](#)
- [Accessing Discovery Information through Built-In Topics \(Chapter 28 on page 359\)](#)

# Chapter 22 Discovery Overview

This section discusses how *Connex* objects on different nodes find out about each other using the default Simple Discovery Protocol (SDP). It describes the sequence of messages that are passed between *Connex* on the sending and receiving sides.

The discovery process occurs automatically, so you do not have to implement any special code. We recommend that all users read this overview and [Chapter 24 Configuring the Peers List Used in Discovery on page 324](#). The remaining sections contain advanced material for those who have a particular need to understand what is happening ‘under the hood.’ This information can help you debug a system in which objects are not communicating.

Discovery is the behind-the-scenes way in which *Connex* objects (*DomainParticipants*, *DataWriters*, and *DataReaders*) on different nodes find out about each other. Each *DomainParticipant* maintains a database of information about all the active *DataReaders* and *DataWriters* that are in the same DDS domain. This database is what makes it possible for *DataWriters* and *DataReaders* to communicate. To create and refresh the database, each application follows a common discovery process.

This chapter describes the default discovery mechanism known as the Simple Discovery Protocol, which includes two phases: [22.1 Simple Participant Discovery on the next page](#) and [22.3 Simple Endpoint Discovery on page 317](#).

The goal of these two phases is to build, for each *DomainParticipant*, a complete picture of all the entities that belong to the remote participants that are in its peers list. The peers list is the list of nodes with which a participant may communicate. It starts out the same as the *initial\_peers* list that you configure in the [44.2 DISCOVERY QosPolicy \(DDS Extension\) on page 699](#). If the *accept\_unknown\_peers* flag in that same QosPolicy is TRUE, then other nodes may also be added as they are discovered; if it is FALSE, then the peers list will match the *initial\_peers* list, plus any peers added using the *DomainParticipant*’s **add\_peer()** operation.

You may also be interested in reading [UDPv4, UDPv6, and Shared Memory Transport Plugins \(Chapter 51 on page 955\)](#), as well as learning about these QosPolicies:

- [48.5 TRANSPORT\\_MULTICAST QosPolicy \(DDS Extension\) on page 891](#)

## 22.1 Simple Participant Discovery

This phase of the Simple Discovery Protocol is performed by the Simple Participant Discovery Protocol (SPDP).

During the Participant Discovery phase, *DomainParticipants* learn about each other. The *DomainParticipant's* details are communicated to all other *DomainParticipants* in the same DDS domain by sending participant messages, also known as *participant DATA* submessages or *participant announcements*. The details include the *DomainParticipant's* unique identifying key (GUID or Globally Unique ID described below), transport locators (addresses and port numbers), and QoS. These messages are sent on a periodic basis using best-effort communication.

*Participant DATAs* are sent periodically to maintain the liveliness of the *DomainParticipant*. They are also used to communicate changes in the *DomainParticipant's* QoS. Only changes to QoS Policies that are part of the *DomainParticipant's* built-in data (namely, the [47.30 USER\\_DATA QosPolicy on page 864](#)) need to be propagated.

When receiving remote participant discovery information, *Connex*t determines if the local participant matches the remote one. A ‘match’ between the local and remote participant occurs only if the local and remote participant have the same domain ID, domain tag, and at least one matching participant partition (see [16.3.4 Choosing a Domain ID and Creating Multiple DDS Domains on page 90](#), [16.3.5.1 Choosing a Domain Tag on page 92](#), and [46.5 PARTITION QosPolicy on page 751](#)). This matching process occurs as soon as the local participant receives discovery information from the remote one. If there is no match, the discovery DATA is ignored, resulting in the remote participant (and all its associated entities) not being discovered.

When a *DomainParticipant* is deleted, a dispose participant message with the *DomainParticipant's* identifying GUID is sent.

The GUID is a unique reference to an entity. It is composed of a GUID prefix and an Entity ID. By default, the GUID prefix is a unique, randomly generated UUID. (For more on how the GUID is calculated, see [44.9.3 Controlling How the GUID is Set \(rtps\\_auto\\_id\\_kind\) on page 732](#).) The IP address and process ID are stored in the *DomainParticipant's* [44.9 WIRE\\_PROTOCOL QosPolicy \(DDS Extension\) on page 730](#). The entityID is set by *Connex*t (you may be able to change it in a future version).

Once a pair of participants have discovered each other, they can move on to the Endpoint Discovery phase, which is how *DataWriters* and *DataReaders* find each other.

You may replace Simple Participant Discovery with Limited Bandwidth Participant Discovery (LBPD), Simple Participant Discovery 2.0 (Experimental), or other discovery protocols. See **builtin\_discovery\_**

**plugins** in the [44.3 DISCOVERY\\_CONFIG QosPolicy \(DDS Extension\) on page 703](#) for more information.

## 22.2 (Experimental) Simple Participant Discovery 2.0

The Simple Participant Discovery Protocol 2.0 (SPDP2) is an experimental alternative to the original Simple Participant Discovery Protocol, described in [22.1 Simple Participant Discovery on the previous page](#). SPDP2 is designed to decrease bandwidth usage and improve the reliability of the participant discovery and update process.

Participant discovery can be broken down into three separate phases: bootstrapping, exchanging configuration, and maintaining liveliness:

- During bootstrapping, a participant sends out periodic messages to its initial peers list in order to discover other matching participants in the system.
- During configuration exchange, a participant makes sure that discovered participants have the most up-to-date information about itself.
- To maintain liveliness, a participant sends out periodic messages to other participants so that they know it is still alive and active.

In SPDP, all of these phases of discovery use the same participant message and send it over a periodic, best-effort channel. This approach is simple and straightforward, but it has a number of drawbacks. The first is that not all phases require the same information to be sent. During bootstrapping, only the information that is needed to determine whether two participants should match needs to be sent (like the domain ID, participant partition, and security configuration). During configuration, any additional information that needs to be communicated to remote participants needs to be sent. And to maintain liveliness, only enough information to identify the participant that is asserting itself needs to be sent. Instead, during all of these phases, all information about a participant is sent, wasting bandwidth with unnecessarily duplicated information.

The second drawback to using the same message sent over the same channel is the lack of flexibility over how often these messages are sent. Messages sent for bootstrapping need to be sent periodically, as frequently as is desired to discover new participants in a system. Configuration messages need to be sent reliably, once upon first communication and then again whenever the participant's configuration changes. SPDP relies on the periodic nature of the messages to repair any losses. So if a configuration update is lost, it is not resent until the next period—which can delay important updates like partition changes or IP mobility events. Finally, liveliness messages need to be sent periodically at a rate that meets the system requirements for detecting when a participant has been lost, which may be a different period than what is required for the other two phases. Instead, SPDP has a single period, **participant\_liveliness\_assert\_period** in the [44.3 DISCOVERY\\_CONFIG QosPolicy \(DDS Extension\) on page 703](#), which configures how often the full participant message is sent.

SPDP2 is designed to address the drawbacks to SPDP by splitting the single message that is sent in SPDP into three different messages—bootstrap messages, configuration messages, and liveliness messages—and by allowing each of these messages to be sent at separately configured periods with different reliability settings.

### Bootstrap Messages

When a participant is first enabled, it sends out **DiscoveryConfigQosPolicy::initial\_participant\_announcements** number of bootstrap messages (see [44.3 DISCOVERY\\_CONFIG QosPolicy \(DDS Extension\) on page 703](#)), at a random period between **DiscoveryConfigQosPolicy::min\_initial\_announcement\_period** and **DiscoveryConfigQosPolicy::max\_initial\_announcement\_period** to all of the locators on its **DiscoveryQosPolicy::initial\_peers** list (see [44.2 DISCOVERY QosPolicy \(DDS Extension\) on page 699](#)). After the initial set of announcements are sent, they are resent to the **DiscoveryQosPolicy::initial\_peers** list at the **DiscoveryConfigQosPolicy::participant\_announcement\_period** in order to match with new participants that may have joined the system. Once a participant receives one of these announcements from a participant that it has not discovered yet, it will respond with **DiscoveryConfigQosPolicy::new\_remote\_participant\_announcements** number of bootstrap messages, also spaced out at a random interval between **DiscoveryConfigQosPolicy::min\_initial\_announcement\_period** and **DiscoveryConfigQosPolicy::max\_initial\_announcement\_period**.

### Configuration Messages

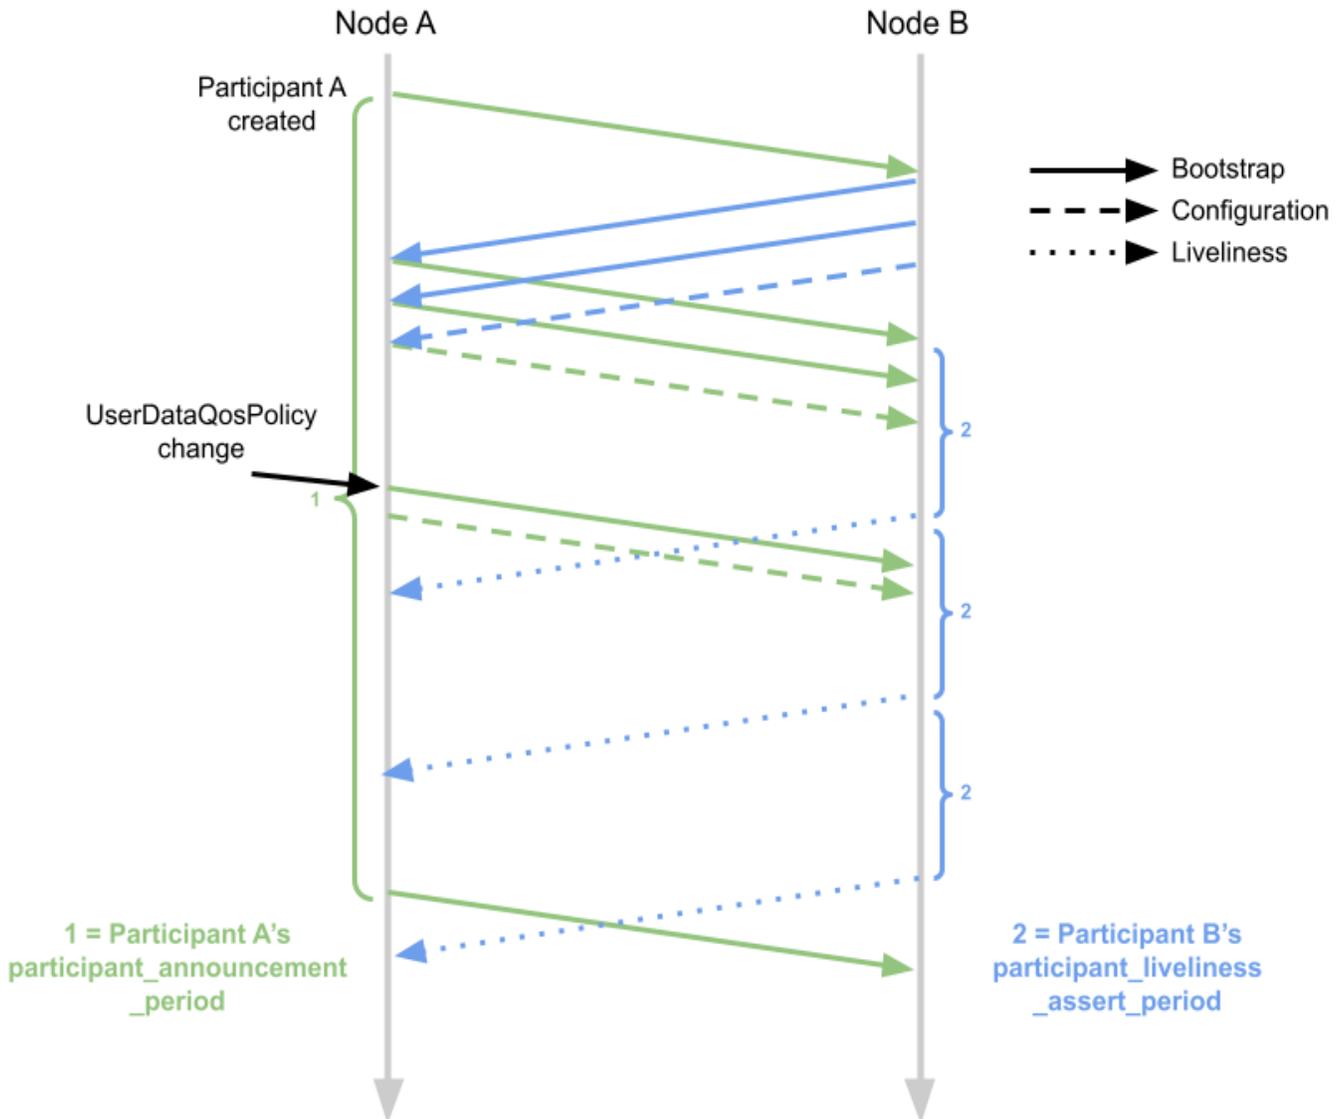

When two participants have received each other's bootstrap messages, they will exchange the rest of their configuration over a reliable channel using another message, the configuration message. In addition to the rest of the configuration that has not been exchanged yet between the two participants, the configuration message also contains fields from the bootstrap message that may change over time, like the participant partition and metatraffic locators. When either participant changes its configuration, this information is sent over this reliable channel.

### Liveliness Messages

Two participants that have completed discovery with each other will exchange periodic bootstrap messages and liveliness messages. In upcoming releases of the protocol, the periodic bootstrap message traffic will be eliminated between two participants that have already discovered each other, and the only ongoing traffic between two participants will be small liveliness messages sent at the **DiscoveryConfigQosPolicy::participant\_liveliness\_assert\_period** (see [44.3 DISCOVERY\\_CONFIG QosPolicy \(DDS Extension\) on page 703](#)).

Currently, there is no way to create a participant that can communicate with participants that are using SPDP at the same time as other participants that are using SPDP2. In upcoming releases, a compatibility mode will be introduced to allow this backwards compatibility.

Figure 22.1: SPDP2: Summary

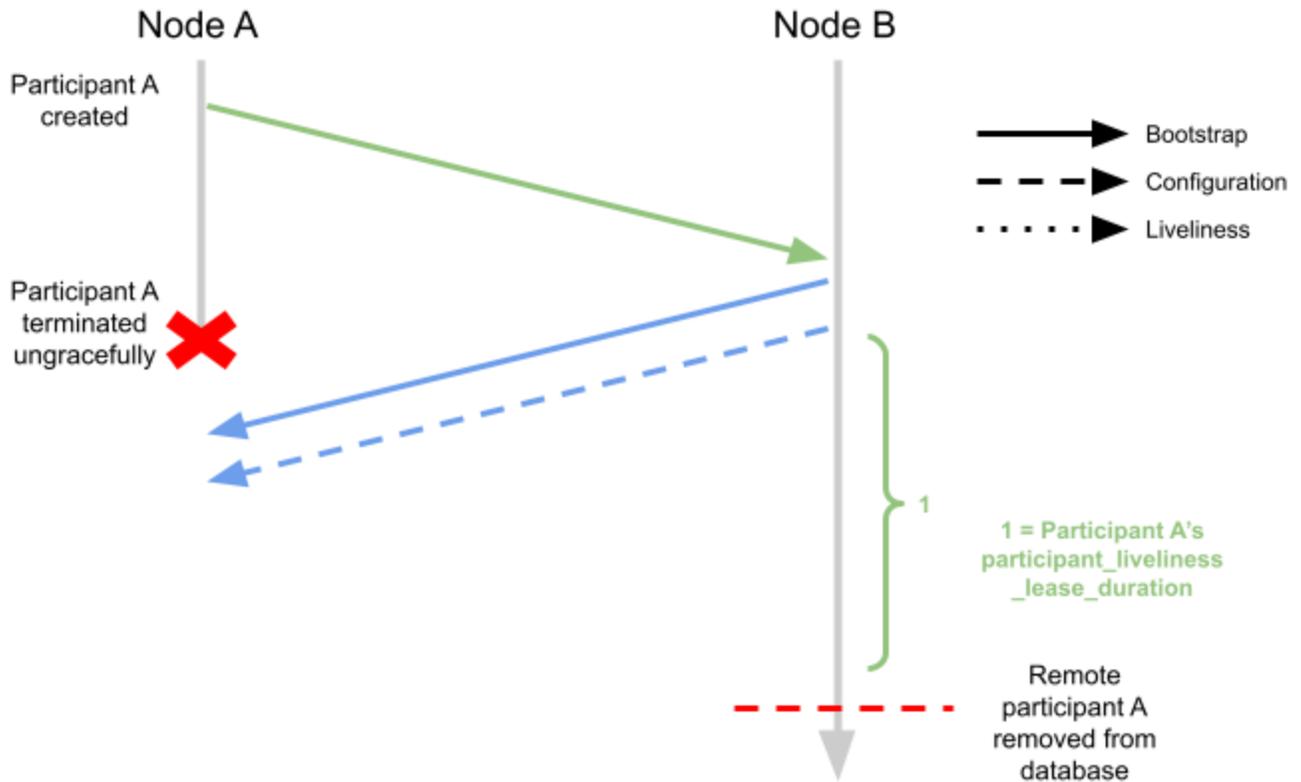

In [Figure 22.1: SPDP2: Summary](#) above, the Participant on Node A sends a bootstrap message to Node B, which is in Node A's peer list. The Participant on Node B sends two bootstrap messages (**new\_remote\_participant\_announcements**) to Node A in response, as well as a configuration message. When the Participant on Node A receives both of these messages and completes compatibility checks, it will consider Participant B as a "matched" participant and begin maintaining liveliness with Participant B. When Participant B receives the configuration message from Participant A, it will also begin maintaining liveliness with Participant A.

Both Participant A and Participant B will continue to send bootstrap messages to their peer list at the rate of their respective **participant\_announcement\_period** (though only Participant A's are illustrated in the diagram for clarity).

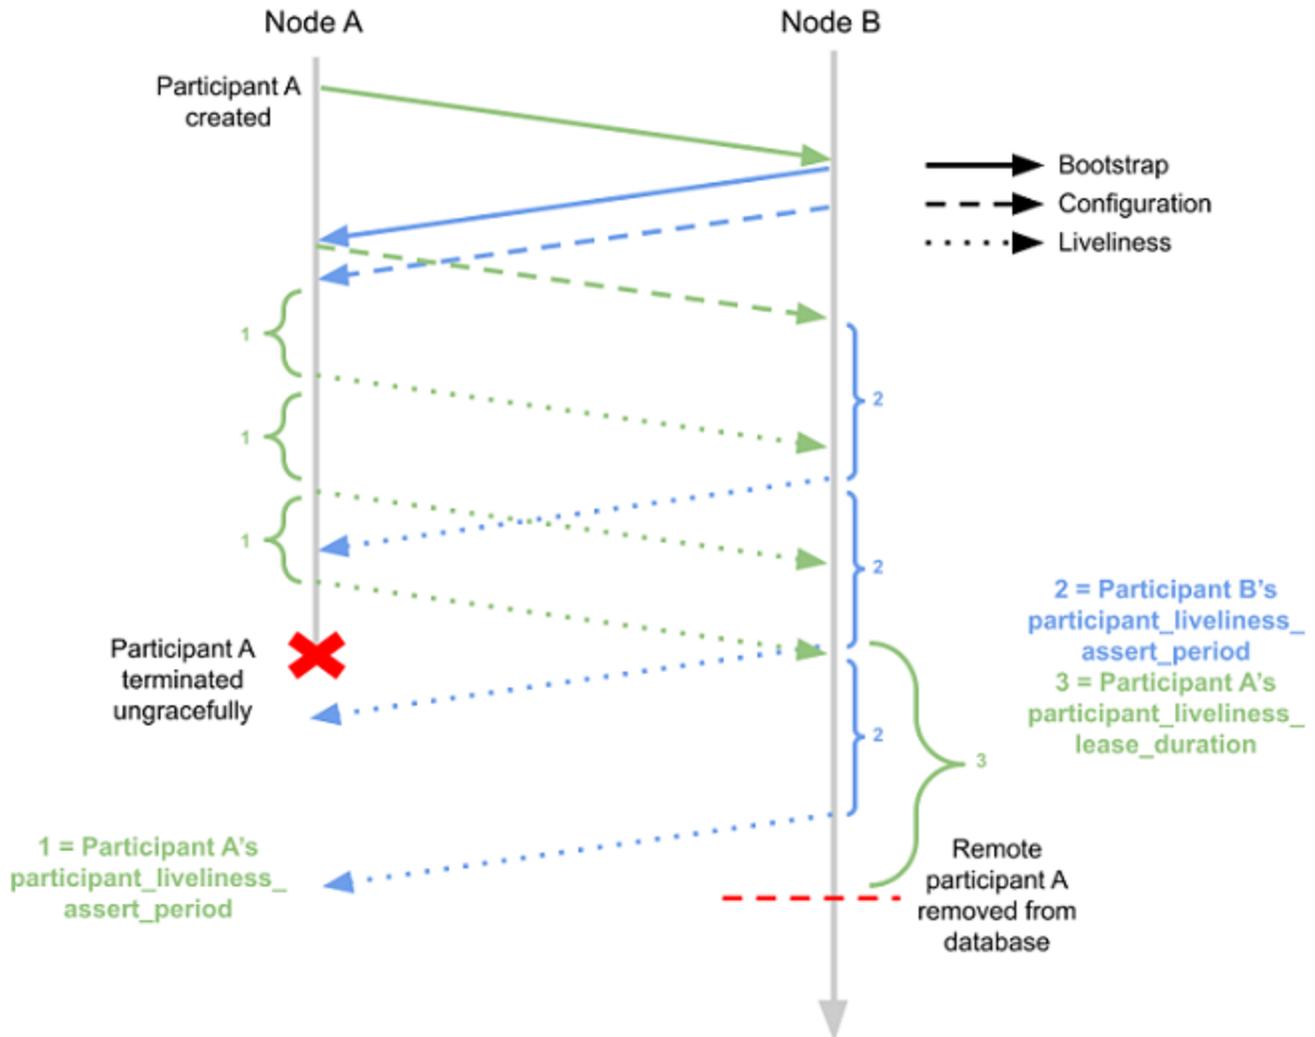

Both Participant A and Participant B will send liveness messages to each other at the rate of their respective **participant\_liveness\_assert\_period** (though only Participant B's are illustrated in the diagram for clarity).

Figure 22.2: SPDP2: Ungraceful Termination before Configuration Exchange Completes

In [Figure 22.2: SPDP2: Ungraceful Termination before Configuration Exchange Completes](#) above, Participant A is removed from Participant B's database if Participant A does not send a configuration message within its **participant\_liveness\_lease\_duration** after it is first discovered by Participant B.

Figure 22.3: SPDP2: Ungraceful Termination after Configuration Exchange Completes

In Figure 22.3: SPDP2: Ungraceful Termination after Configuration Exchange Completes above, Participant A is removed from Participant B's database if it does not send a liveliness message within its `participant_liveliness_lease_duration`.

## 22.2.1 Bootstrap Message Fields

The following fields are sent as part of the periodic, best-effort bootstrap message:

- Also sent in the configuration message:
  - *DomainParticipant's* GUID
  - Metatraffic unicast locators
  - Metatraffic multicast locators

- Participant partition
- Vendor builtin endpoint mask
  
- Domain ID
- Domain tag
- Product version
- Participant liveness lease duration
- Transport info
- [47.23 SERVICE QosPolicy \(DDS Extension\) on page 853](#)
- Security info
- Security tokens
- Security signature algorithms
- Security key establishment algorithms
- Security participant symmetric cipher algorithms

## 22.2.2 Configuration Message Fields

The following fields are sent as part of the reliable configuration message:

- Also sent in the bootstrap message:
  - *DomainParticipant's* GUID
  - Metatraffic unicast locators
  - Metatraffic multicast locators
  - Participant partition
  - Vendor builtin endpoint mask
  
- Participant name
- [47.19 PROPERTY QosPolicy \(DDS Extension\) on page 837](#)
- Default unicast locators
- Default multicast locators
- Builtin endpoint mask
- Builtin endpoint qos mask
- Reachability lease duration
- [47.30 USER\\_DATA QosPolicy on page 864](#)

## 22.2.3 Unsupported Features with SPDP2

The following features are known to not work when using the SPDP2 protocol:

- *RTI Cloud Discovery Service*
- Custom security plugins. Only the *RTI Security Plugins* are supported in combination with SPDP2.

## 22.2.4 Planned Improvements to SPDP2

The SPDP2 protocol is still under development with a number of improvements planned for upcoming releases. These include:

- A compatibility mode. The compatibility mode will allow some participants to act as bridges between participants that are using SPDP and SPDP2. Participants that are using the compatibility mode will be able to communicate with participants that are using SPDP and other participants that are using SPDP2. Participants that are using SPDP cannot communicate directly with participants that are using SPDP2.
- Reduced bootstrap traffic after matching with a participant. When a participant matches with another participant that is located at one of its initial peers locators, it will stop sending periodic bootstrap messages to the matched participant. Any configuration updates will be sent over the reliable configuration channel so there is no need for the continued periodic bootstrap messages to go to matched participants.
- Improved configuration update behavior. Currently, when a participant changes its configuration (partition, locators, etc.), it sends out:
  - If SPDP is enabled: a single Data(p) to all peers (matched or potential)
  - If SPDP2 is enabled: a single reliable message to matched peers, a single bootstrap message to unmatched initial peers

RTI will add an option to send multiple Data(p)s/bootstrap messages, since these messages are sent best-effort and can get lost, delaying configuration change updates in remote participants until the next periodic message. RTI will also ensure that when a configuration change causes two participants to no longer match (i.e., a partition change), the participant that changed its partition waits for the remote participants to acknowledge reception of this change.

## 22.3 Simple Endpoint Discovery

This phase of the Simple Discovery Protocol is performed by the Simple Endpoint Discovery Protocol (SEDP).

During the Endpoint Discovery phase, *Connex* matches *DataWriters* and *DataReaders*. Information (GUID, QoS, etc.) about your application's *DataReaders* and *DataWriters* is exchanged by sending

publication/subscription declarations in DATA messages that we will refer to as *publication DATAs* and *subscription DATAs*. The Endpoint Discovery phase uses reliable communication.

As described in [Chapter 25 Discovery: Under the Hood on page 331](#), these declaration or DATA messages are exchanged until each *DomainParticipant* has a complete database of information about the participants in its peers list and their entities. Then the discovery process is complete and the system switches to a steady state. During steady state, *participant DATAs* are still sent periodically to maintain the liveness status of participants. They may also be sent to communicate QoS changes or the deletion of a *DomainParticipant*.

When a remote *DataWriter/DataReader* is discovered, *Connex*t determines if the local application has a matching *DataReader/DataWriter*. A ‘match’ between the local and remote entities occurs only if the *DataReader* and *DataWriter* have the same *Topic*, same data type, and compatible QoS Policies (which includes having the same partition name string, see [46.5 PARTITION QoS Policy on page 751](#)). Furthermore, if the *DomainParticipant* has been set up to ignore certain *DataWriters/DataReaders*, those entities will not be considered during the matching process. See [27.2 Ignoring Publications and Subscriptions on page 354](#) for more on ignoring specific publications and subscriptions.

This ‘matching’ process occurs as soon as a remote entity is discovered, even if the entire database is not yet complete: that is, the application may still be discovering other remote entities.

A *DataReader* and *DataWriter* can only communicate with each other if each one’s application has hooked up its local entity with the matching remote entity. That is, both sides must agree to the connection.

[Chapter 25 Discovery: Under the Hood on page 331](#) describes the details about the discovery process.

You may replace Simple Endpoint Discovery with Limited Bandwidth Endpoint Discovery (LBED) or other discovery protocols. See **`builtin_discovery_plugins`** in the [44.3 DISCOVERY\\_CONFIG QoS Policy \(DDS Extension\) on page 703](#) for more information.

## Chapter 23 Ports Used for Discovery

There are two kinds of traffic in a *Connex* application: discovery (meta) traffic, and user traffic. Meta-traffic is for data (declarations) that is sent between the automatically-created discovery writers and readers; user traffic is for data that is sent between user-created *DataWriters* and *DataReaders*. To keep the two kinds of traffic separate, *Connex* uses different ports, as described below.

**Note:** The ports described in this section are used for *incoming* data. *Connex* uses ephemeral ports for outbound data.

*Connex* uses the RTPS wire protocol. The discovery protocols defined by RTPS rely on well-known ports to initiate discovery. These well-known ports define the multicast and unicast ports on which a Participant will listen for meta-traffic from other Participants. The meta-traffic contains the information required by *Connex* to establish the presence of remote *Entities* in the network.

The well-known incoming ports are defined by RTPS in terms of port mapping expressions with several tunable parameters. This allows you to customize what network ports are used for receiving data by *Connex*. These parameters are shown in [Table 23.1 WireProtocol QosPolicy's rtps\\_well\\_known\\_ports \(DDS\\_RtpsWellKnownPorts\\_t\)](#). (For defaults and valid ranges, please see the API Reference HTML documentation.)

**Table 23.1** WireProtocol QosPolicy's rtps\_well\_known\_ports (DDS\_RtpsWellKnownPorts\_t)

Type	Field Name	Description
DDS_Long	port_base	The base port offset. All mapped well-known ports are offset by this value. Resulting ports must be within the range imposed by the underlying transport.
	domain_id_gain	Tunable gain parameters. See <a href="#">23.4 Tuning domain_id_gain and participant_id_gain on page 322</a> .
	participant_id_gain	
	builtin_multicast_port_offset	Additional offset for meta-traffic port. See <a href="#">23.1 Inbound Ports for Meta-Traffic on the next page</a> .
	builtin_unicast_port_offset	
	user_multicast_port_offset	Additional offset for user traffic port. See <a href="#">23.2 Inbound Ports for User Traffic on the next page</a> .
	user_unicast_port_offset	

In order for all Participants in a system to correctly discover each other, it is important that they all use the same port mapping expressions.

In addition to the parameters listed in [Table 23.1 WireProtocol QosPolicy's rtps\\_well\\_known\\_ports \(DDS\\_RtpsWellKnownPorts\\_t\)](#), the port formulas described below depend on:

- The domain ID specified when the *DomainParticipant* is created (see [16.3.1 Creating a DomainParticipant on page 87](#)). The domain ID ensures no port conflicts exist between Participants belonging to different domains. This also means that discovery traffic in one DDS domain is not visible to *DomainParticipants* in other DDS domains.
- The **participant\_id** is a field in the [44.9 WIRE\\_PROTOCOL QosPolicy \(DDS Extension\) on page 730](#), see [44.9.1 Choosing Participant IDs on page 730](#). The **participant\_id** ensures that unique unicast port numbers are assigned to *DomainParticipants* belonging to the same DDS domain on a given host.

**Backwards Compatibility:** *Connex* supports the standard DDS Interoperability Wire Protocol based on the Real-time Publish-Subscribe (RTPS) protocol. This protocol is not compatible with the one used by earlier releases (4.2c or lower). Therefore, applications built with 4.2d or higher will not interoperate with applications built with 4.2c or lower. The default port mapping from domainID and participant index has also been changed according to the new interoperability specification. The message types and formats used by RTPS have also changed.

**Port Aliasing:** When modifying the port mapping parameters, *avoid port aliasing*. This would result in undefined discovery behavior. The chosen parameter values will also determine the maximum possible number of DDS domains in the system and the maximum number of participants per DDS domain.

Additionally, any resulting mapped port number must be within the range imposed by the underlying transport. For example, for UDPv4, this range typically equals [1024 - 65535].

## 23.1 Inbound Ports for Meta-Traffic

The Wire Protocol QosPolicy's `rtps_well_known_ports.metatraffic_unicast_port` determines the port used for receiving meta-traffic using unicast:

```
metatraffic_unicast_port = port_base +
    (domain_id_gain * domain ID) +
    (participant_id_gain * participant_id) +
    builtin_unicast_port_offset
```

Similarly, `rtps_well_known_ports.metatraffic_multicast_port` determines the port used for receiving meta-traffic using multicast. The corresponding multicast group addresses are specified via `multicast_receive_addresses` (see [44.2.4 Configuring Multicast Receive Addresses on page 701](#)).

```
metatraffic_multicast_port = port_base +
    (domain_id_gain * domain ID) +
    builtin_multicast_port_offset
```

**Note:** Multicast is only used for meta-traffic if a multicast address is specified in the `NDDS_DISCOVERY_PEERS` environment variable or file or if the `multicast_receive_addresses` field of the [44.3 DISCOVERY\\_CONFIG QosPolicy \(DDS Extension\) on page 703](#) is set.

## 23.2 Inbound Ports for User Traffic

RTPS also defines the default multicast and unicast ports on which *DataReaders* and *DataWriters* receive user traffic. These default ports can be overridden using the *DataReader's* [48.5 TRANSPORT\\_MULTICAST QosPolicy \(DDS Extension\) on page 891](#) and [47.28 TRANSPORT\\_UNICAST QosPolicy \(DDS Extension\) on page 859](#), or the *DataWriter's* [47.28 TRANSPORT\\_UNICAST QosPolicy \(DDS Extension\) on page 859](#).

The WireProtocol QosPolicy's `rtps_well_known_ports.usertraffic_unicast_port` determines the port used for receiving user data using unicast:

```
usertraffic_unicast_port =
    port_base +
    (domain_id_gain * domain ID) +
    (participant_id_gain * participant_id) +
    user_unicast_port_offset
```

Similarly, `rtps_well_known_ports.usertraffic_multicast_port` determines the port used for receiving user data using multicast. The corresponding multicast group addresses can be configured using the [47.28 TRANSPORT\\_UNICAST QosPolicy \(DDS Extension\) on page 859](#).

```

usertraffic_multicast_port =
    port_base +
    (domain_id_gain * domain ID) +
    user_multicast_port_offset

```

## 23.3 Automatic Selection of participant\_id and Port Reservation

The [44.9 WIRE\\_PROTOCOL QoSPolicy \(DDS Extension\) on page 730](#) `rtps_reserved_ports_mask` field determines what type of ports are reserved when the *DomainParticipant* is enabled. See [44.9.1 Choosing Participant IDs on page 730](#).

## 23.4 Tuning domain\_id\_gain and participant\_id\_gain

The `domain_id_gain` is used as a multiplier of the domain ID. Together with `participant_id_gain` ([23.4 Tuning domain\\_id\\_gain and participant\\_id\\_gain above](#)), these values determine the highest domain ID and `participant_id` allowed on this network.

In general, there are two ways to set up the `domain_id_gain` and `participant_id_gain` parameters.

- If `domain_id_gain > participant_id_gain`, it results in a port mapping layout where all *DomainParticipants* in a DDS domain occupy a consecutive range of `domain_id_gain` ports. Precisely, all ports occupied by the DDS domain fall within:

```
(port_base + (domain_id_gain * domain ID))
```

and:

```
(port_base + (domain_id_gain * (domain ID + 1)) - 1)
```

In this case, the highest domain ID is limited only by the underlying transport's maximum port. The highest `participant_id`, however, must satisfy:

```
max_participant_id < (domain_id_gain / participant_id_gain)
```

- Or if `domain_id_gain <= participant_id_gain`, it results in a port mapping layout where a given DDS domain's *DomainParticipant* instances occupy ports spanned across the entire valid port range allowed by the underlying transport. For instance, it results in the following potential mapping:

Mapped Port	Domain ID	Participant ID
higher port number	1	2
	0	
	1	1
0		
lower port number	1	0
	0	

In this case, the highest **participant\_id** is limited only by the underlying transport's maximum port. The highest **domain\_id**, however, must satisfy:

```
max_domain_id < (participant_id_gain / domain_id_gain)
```

The **domain\_id\_gain** also determines the range of the port-specific offsets:

```
domain_id_gain >
abs(builtin_multicast_port_offset - user_multicast_port_offset)
```

and

```
domain_id_gain >
abs(builtin_unicast_port_offset - user_unicast_port_offset)
```

Violating this may result in port aliasing and undefined discovery behavior.

The **participant\_id\_gain** also determines the range of **builtin\_unicast\_port\_offset** and **user\_unicast\_port\_offset**.

```
participant_id_gain >
abs(builtin_unicast_port_offset - user_unicast_port_offset)
```

In all cases, the resulting ports must be within the range imposed by the underlying transport.

# Chapter 24 Configuring the Peers List Used in Discovery

As part of the participant phase of the discovery process, *Connex* will announce itself within the DDS domain. *Connex* will try to contact all possible participants in the ‘initial peers list,’ specified in the *DomainParticipant*’s [44.2 DISCOVERY QoS Policy \(DDS Extension\) on page 699](#). Note, however, it is not known if there are actually *Connex* applications running on the hosts in the initial peers list. The initial peers list may include both unicast and multicast peer locators.

After startup, you can add to the ‘peers list’ with the **add\_peer()** operation (see [44.2.3 Adding and Removing Peers List Entries on page 700](#)). The ‘peers list’ may also grow as peers are automatically discovered (if `accept_unknown_peers` is TRUE, see [44.2.6 Controlling Acceptance of Unknown Peers on page 701](#)).

When you call **get\_default\_participant\_qos()** for a *DomainParticipantFactory*, the values used for the *DiscoveryQoSPolicy*’s **initial\_peers** and **multicast\_receive\_addresses** may come from the following:

- A file named **NDDS\_DISCOVERY\_PEERS**, which is formatted as described in [24.3 NDDS\\_DISCOVERY\\_PEERS File Format on page 329](#). The file must be in your application’s current working directory.
- An environment variable named **NDDS\_DISCOVERY\_PEERS**, defined as a comma-separated list of peer descriptors (see [24.2 NDDS\\_DISCOVERY\\_PEERS Environment Variable Format on page 328](#)).
- The value specified in the default XML QoS profile (see [50.4 Tags for Configuring QoS with XML on page 931](#)).

If **NDDS\_DISCOVERY\_PEERS** (file or environment variable) does *not* contain a multicast address, then **multicast\_receive\_addresses** is cleared and the RTI discovery process will not listen for discovery messages via multicast.

If `NDDS_DISCOVERY_PEERS` (file or environment variable) contains one or more multicast addresses, the addresses are stored in `multicast_receive_addresses`, starting at element 0. They will be stored in the order in which they appear in `NDDS_DISCOVERY_PEERS`.

**Note:** Setting `initial_peers` in the default XML QoS Profile does not modify the value of `multicast_receive_address`.

If both the file and environment variable are found, the file takes precedence and the environment variable will be ignored.<sup>1</sup> The settings in the default XML QoS Profile take precedence over the file and environment variable. In the absence of a file, environment variable, or default XML QoS profile values, *Connex*t will use a default value. See the API Reference HTML documentation for details (in the section on the DISCOVERY QoS Policy).

If initial peers are specified in both the currently loaded QoS XML profile and in the `NDDS_DISCOVERY_PEERS` file, the values in the profile take precedence.

The file, environment variable, and default XML QoS Profile make it easy to reconfigure which nodes will take part in the discovery process—without recompiling your application.

The file, environment variable, and default XML QoS Profile are the possible sources for the *default* initial peers list. You can, of course, explicitly set the initial list by changing the values in the QoS provided to the `DomainParticipantFactory`'s `create_participant()` operation, or by adding to the list after startup with the *DomainParticipant*'s `add_peer()` operation (see [44.2.3 Adding and Removing Peers List Entries on page 700](#)).

#### **If you set `NDDS_DISCOVERY_PEERS` and You Want to Communicate over Shared Memory:**

Suppose you want to communicate with other *Connex*t applications on the same host and you are explicitly setting `NDDS_DISCOVERY_PEERS` (generally in order to use unicast discovery with applications on other hosts).

If the local host platform does *not* support the shared memory transport, then you can include the name of the local host in the `NDDS_DISCOVERY_PEERS` list. (To check if your platform supports shared memory, see the [RTI Connex Core Libraries Platform Notes](#).)

If the local host platform supports the shared memory transport, then you must do one of the following:

- Include `"shmem://"` in the `NDDS_DISCOVERY_PEERS` list. This will cause shared memory to be used for discovery and data traffic for applications on the same host.

or:

---

<sup>1</sup>This is true even if the file is empty.

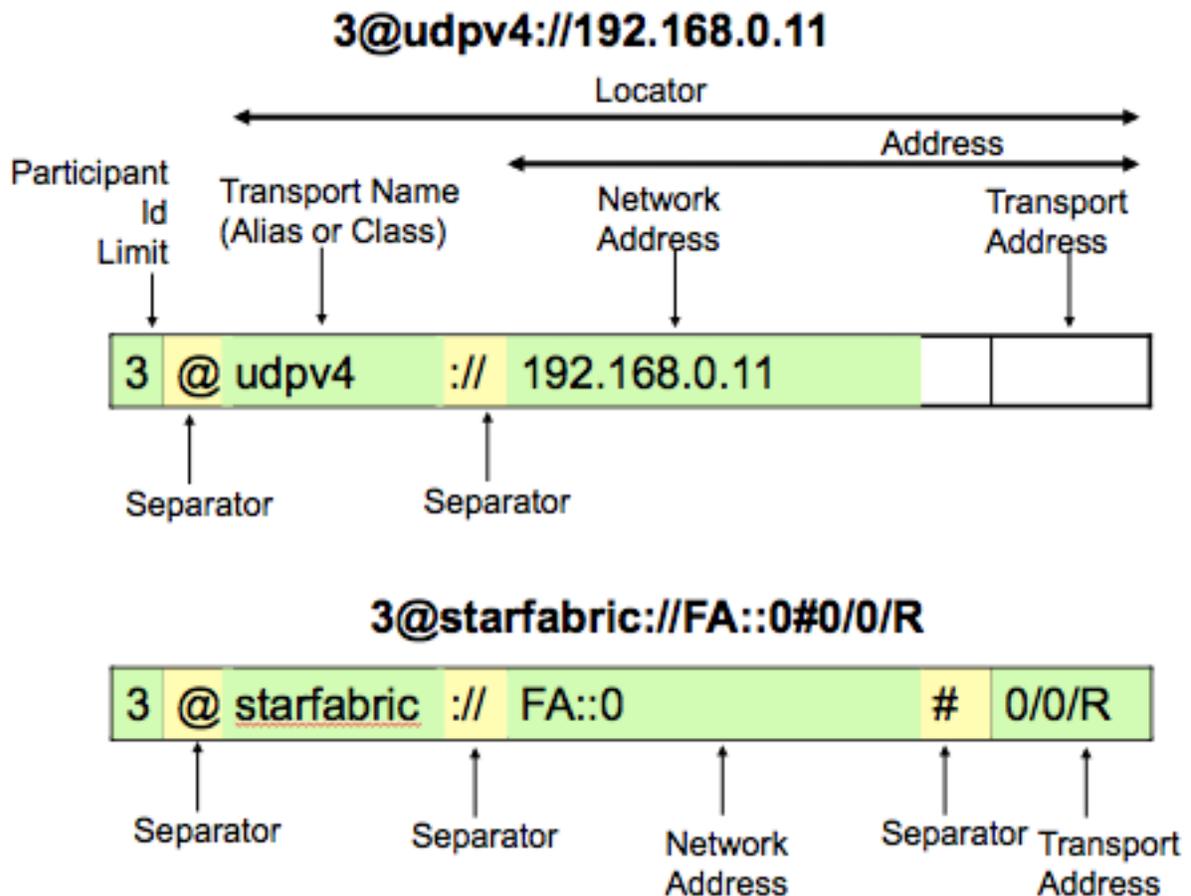

- Include the name of the local host in the `NDDS_DISCOVERY_PEERS` list, and disable the shared memory transport in the [44.7 TRANSPORT\\_BUILTIN QosPolicy \(DDS Extension\) on page 725](#) of the *DomainParticipant*. This will cause UDP loopback to be used for discovery and data traffic for applications on the same host.

## 24.1 Peer Descriptor Format

A peer descriptor string specifies a range of participants at a given locator. Peer descriptor strings are used in the [44.2 DISCOVERY QosPolicy \(DDS Extension\) on page 699](#) `initial_peers` field (see [44.2.2 Setting the 'Initial Peers' List on page 700](#)) and the *DomainParticipant*'s `add_peer()` and `remove_peer()` operations (see [44.2.3 Adding and Removing Peers List Entries on page 700](#)).

The anatomy of a peer descriptor is illustrated in [Figure 24.1: Example Peer Descriptor Address Strings below](#) using a special "StarFabric" transport example.

Figure 24.1: Example Peer Descriptor Address Strings

A peer descriptor consists of:

- *[optional]* A participant ID limit. If a simple integer is specified, it indicates the maximum participant ID to be contacted by the *Connex* discovery mechanism at the given locator. If that integer is enclosed in square brackets (e.g., [2]), then *only* that Participant ID will be used. You can also specify a range in the form of **[a-b]**: in this case only the Participant IDs in that specific range are contacted. If omitted, a default value of 4 is implied and participant IDs 0, 1, 2, 3, and 4 will be contacted.
- A locator, as described in [24.1.1 Locator Format below](#).

These are separated by the '@' character. The separator may be omitted if a participant ID limit is not explicitly specified.

The "participant ID limit" only applies to unicast locators; it is ignored for multicast locators (and therefore should be omitted for multicast peer descriptors).

### 24.1.1 Locator Format

A locator string specifies a transport and an address in string format. Locators are used to form peer descriptors. A locator is equivalent to a peer descriptor with the default participant ID limit (4).

A locator consists of:

- *[optional]* Transport name (alias or class). This identifies the set of transport plug-ins (transport aliases) that may be used to parse the address portion of the locator. Note that a transport class name is an implicit alias used to refer to all the transport plug-in instances of that class.
- *[optional]* An address, as described in [24.1.2 Address Format on the next page](#).

These are separated by the "://" string. The separator is specified if and only if a transport name is specified.

If a transport name is specified, the address may be omitted; in that case all the unicast addresses (across all transport plug-in instances) associated with the transport class are implied. Thus, a locator string may specify several addresses.

If an address is specified, the transport name and the separator string may be omitted; in that case all the available transport plug-ins for the *Entity* may be used to parse the address string.

The transport names for the built-in transport plug-ins are:

- shmem - Shared Memory Transport
- udpv4 - UDPv4 Transport
- udpv6 - UDPv6 Transport

## 24.1.2 Address Format

An address string specifies a transport-independent network address that qualifies a transport-dependent address string. Addresses are used to form locators. Addresses are also used in the [44.2 DISCOVERY QosPolicy \(DDS Extension\) on page 699](#) `multicast_receive_addresses` and the `DDS_TransportMulticastSettings_t::receive_address` fields. An address is equivalent to a locator in which the transport name and separator are omitted.

An address consists of:

- *[optional]* A network address in IPv4 or IPv6 string notation. If omitted, the network address of the transport is implied.
- *[optional]* A transport address, which is a string that is passed to the transport for processing. The transport maps this string into `NDDS_Transport_Property_t::address_bit_count` bits. If omitted, the network address is used as the fully qualified address. The transport plugin sets the value for `NDDS_Transport_Property_t::address_bit_count` bits.

The network and transport addresses are separated by the '#' character. If a separator is specified, it must be followed by a non-empty string that is passed to the transport plug-in. If the separator is omitted, it is treated as a transport address with an implicit network address (of the transport plugin). The implicit network address is the address used when registering the transport: e.g., the UDPv4 implicit network address is 0.0.0.0.0.0.0.0.0.0.

The bits resulting from the transport address string are prepended with the network address. The least significant `NDDS_Transport_Property_t::address_bit_count` bits of the network address are ignored.

## 24.2 NDDS\_DISCOVERY\_PEERS Environment Variable Format

You can set the default value for the initial peers list in an environment variable named `NDDS_DISCOVERY_PEERS`. Multiple peer descriptor entries must be separated by commas. [Table 24.1 NDDS\\_DISCOVERY\\_PEERS Environment Variable Examples](#) shows some examples. The examples use an implied maximum participant ID of 4 unless otherwise noted. (If you need instructions on how to set environment variables, see Set Up Environment Variables (`rtisetenv`), in "Hands-On 1" of *Introduction to Publish/Subscribe*, in the [RTI Connext Getting Started Guide](#).)

**Table 24.1 NDDS\_DISCOVERY\_PEERS Environment Variable Examples**

NDDS_DISCOVERY_PEERS	Description of Host(s)
239.255.0.1	multicast
localhost	localhost

**Table 24.1 NDDS\_DISCOVERY\_PEERS Environment Variable Examples**

NDDS_DISCOVERY_PEERS	Description of Host(s)
192.168.1.1	10.10.30.232 (IPv4)
FAA0::1	FAA0::0 (IPv6)
himalaya,gangotri	himalaya and gangotri
1@himalaya,1@gangotri	himalaya and gangotri (with a maximum participant ID of 1 on each host)
FAA0:0#localhost	FAA0:0#localhost (could be a UDPv4 transport plug-in registered at network address of FAA0:0) (IPv6)
udpv4://himalaya	himalaya accessed using the "udpv4" transport plug-in (IPv4)
udpv4://FAA0:0#localhost	localhost using the "udpv4" transport plug-in registered at network address FAA0:0
0/0/R #0/0/R	0/0/R (StarFabric)
starfabric://0/0/R starfabric://#0/0/R	0/0/R (StarFabric) using the "starfabric" (StarFabric) transport plug-ins
starfabric://FBB0:0#0/0/R	0/0/R (StarFabric) using the "starfabric" (StarFabric) transport plug-ins registered at network address FAA0:0
starfabric://	all unicast addresses accessed via the "starfabric" (StarFabric) transport plug-ins
shmem://FCC0:0	all unicast addresses accessed via the "shmem" (shared memory) transport plug-ins registered at network address FCC0:0

## 24.3 NDDS\_DISCOVERY\_PEERS File Format

You can set the default value for the initial peers list in a file named `NDDS_DISCOVERY_PEERS`. The file must be in your application's current working directory.

The file is optional. If it is found, it supersedes the values in any environment variable of the same name.

Entries in the file must contain a sequence of peer descriptors separated by whitespace or the comma (',') character. The file may also contain comments starting with a semicolon (;) character until the end of the line.

**Example file contents:**

```
;; NDDS_DISCOVERY_PEERS - Discovery Configuration File
;; Multicast builtin.udpv4://239.255.0.1 ; default discovery multicast addr

;; Unicast
localhost,192.168.1.1      ; A comma can be used a separator
FAA0::1 FAA0::0#localhost ; Whitespace can be used as a separator
1@himalaya                ; Max participant ID of 1 on 'himalaya'
1@gangotri

;; UDPv4
udpv4://himalaya          ; 'himalaya' via 'udpv4' transport plugin(s)
udpv4://FAA0::0#localhost ; 'localhost' via 'udpv4' transport plugin
                          ; registered at network address FAA0::0

;; Shared Memory
shmem://                  ; All 'shmem' transport plugin(s)
builtin.shmem://          ; The builtin builtin 'shmem' transport plugin
shmem://FCC0::0           ; Shared memory transport plugin registered
                          ; at network address FCC0::0

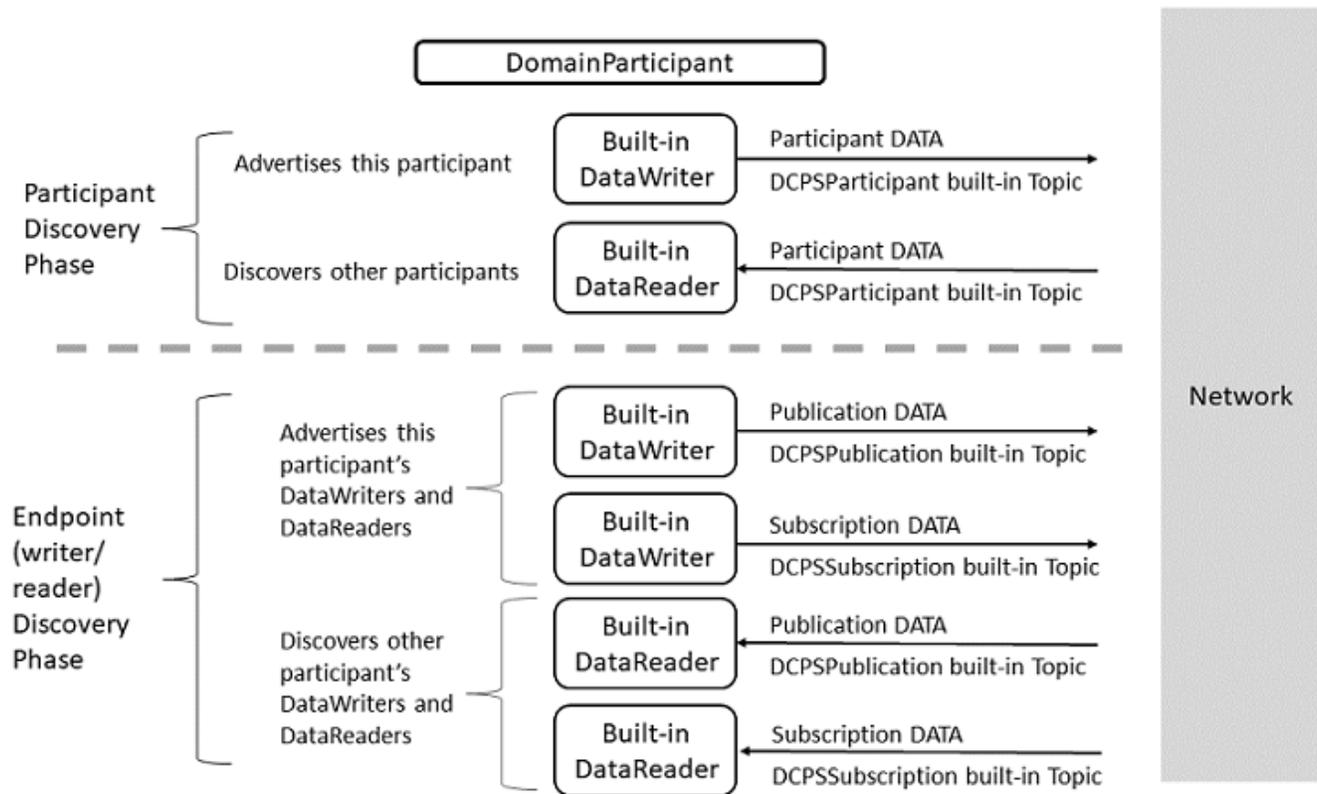

;; StarFabric
0/0/R                     ; StarFabric node 0/0/R
starfabric://0/0/R        ; 0/0/R accessed via 'starfabric'
                          ; transport plugin(s)
starfabric://FBB0::0#0/0/R ; StarFabric transport plugin registered
                          ; at network address FBB0::0
starfabric://             ; All 'starfabric' transport plugin(s)
```

# Chapter 25 Discovery: Under the Hood

**Note:** this section contains advanced material not required by most users.

Discovery is implemented using built-in *DataWriters* and *DataReaders*. These are the same class of entities your application uses to send/receive data. That is, they are also of type *DDSDataWriter/DDSDataReader*. For each *DomainParticipant*, three built-in *DataWriters* and three *built-in DataReaders* are automatically created for discovery purposes. [Figure 25.1: Built-in Writers and Readers for Discovery on the next page](#) shows how these objects are used. (For more on built-in *DataReaders* and *DataWriters*, see [Accessing Discovery Information through Built-In Topics \(Chapter 28 on page 359\)](#)).

Figure 25.1: Built-in Writers and Readers for Discovery

For each `DomainParticipant`, there are six objects automatically created for discovery purposes. The top two objects are used to send/receive participant `DATA` messages, which are used in the Participant Discovery phase to find remote `DomainParticipants`. This phase uses best-effort communications. Once the participants are aware of each other, they move on to the Endpoint Discovery Phase to learn about each other's `DataWriters` and `DataReaders`. This phase uses reliable communications.

The implementation is split into two separate protocols:

Simple Participant Discovery Protocol (SPDP)  
 + Simple Endpoint Discovery Protocol (SEDP)

= Simple Discovery Protocol (SDP)

## 25.1 Participant Discovery

When a `DomainParticipant` is created, a `DataWriter` and a `DataReader` are automatically created to exchange `participant DATA` messages in the network. These `DataWriters` and `DataReaders` are "special" because the `DataWriter` can send to a given list of destinations, regardless of whether there is a `Connex` application at the destination, and the `DataReader` can receive data from any source, whether the source is previously known or not. In other words, these special readers and writers do not need to discover the remote entity and perform a match before they can communicate with each other.

When a *DomainParticipant* joins or leaves the network, it needs to notify its peer participants. The list of remote participants to use during discovery comes from the peer list described in the [44.2 DISCOVERY QoSPolicy \(DDS Extension\) on page 699](#). The remote participants are notified via *participant DATA* messages. In addition, if a participant's QoS is modified in such a way that other participants need to know about the change (that is, changes to the [47.30 USER\\_DATA QoSPolicy on page 864](#)), a new *participant DATA* will be sent immediately.

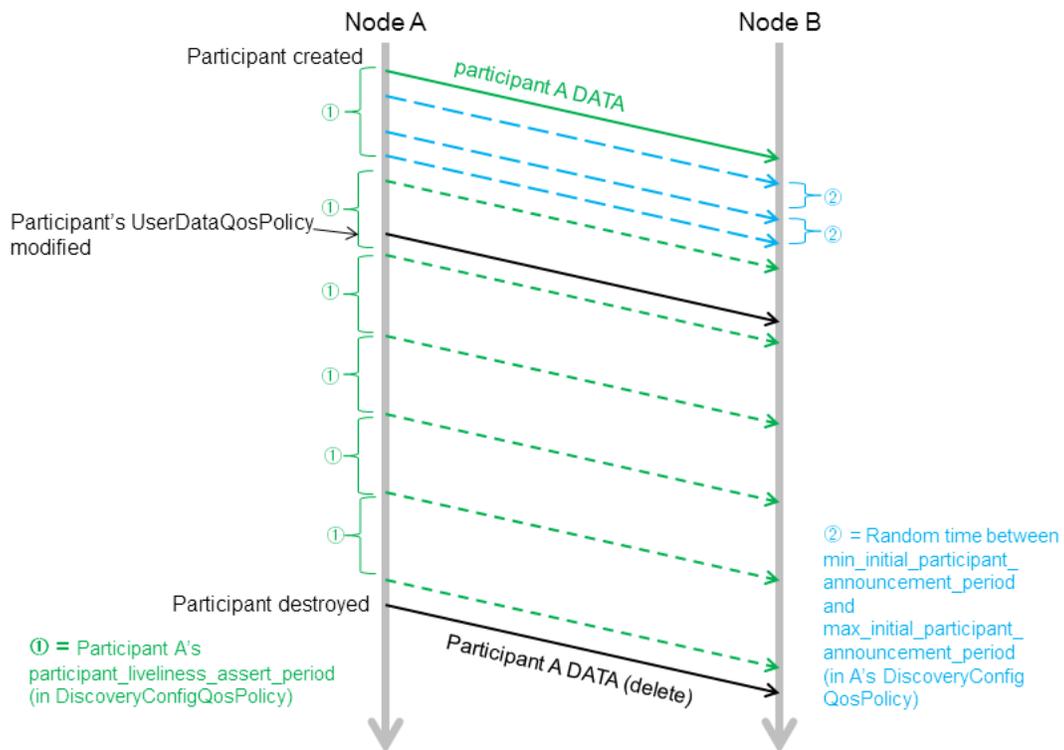

Participant DATAs are also used to maintain a participant's liveness status. These are sent at the rate set in the **participant\_liveness\_assert\_period** in the [44.3 DISCOVERY\\_CONFIG QoSPolicy \(DDS Extension\) on page 703](#).

Let's examine what happens when a new remote participant is discovered. If the new remote participant is in the local participant's peer list, the local participant will add that remote participant into its database. If the new remote participant is not in the local application's peer list, it may still be added, if the **accept\_unknown\_peers** field in the [44.2 DISCOVERY QoSPolicy \(DDS Extension\) on page 699](#) is set to TRUE.

Once a remote participant has been added to the *Connex* database, *Connex* keeps track of that remote participant's **participant\_liveness\_lease\_duration**. If a *participant DATA* for that participant (identified by the GUID) is not received at least once within the **participant\_liveness\_lease\_duration**, the remote participant is considered stale, and the remote participant, together with all its entities, will be removed from the database of the local participant.

To keep from being purged by other participants, each participant needs to periodically send a *participant DATA* to refresh its liveness. The rate at which the *participant DATA* is sent is controlled by the **participant\_liveness\_assert\_period** in the participant's [44.3 DISCOVERY\\_CONFIG QoSPolicy \(DDS Extension\) on page 703](#). This exchange, which keeps Participant A from appearing 'stale,' is illustrated in [Figure 25.2: Periodic 'participant DATAs' on the next page](#). [Figure 25.3: Ungraceful Termination of a Participant on page 335](#) shows what happens when Participant A terminates ungracefully and therefore needs to be seen as 'stale.'

Figure 25.2: Periodic 'participant DATAs'

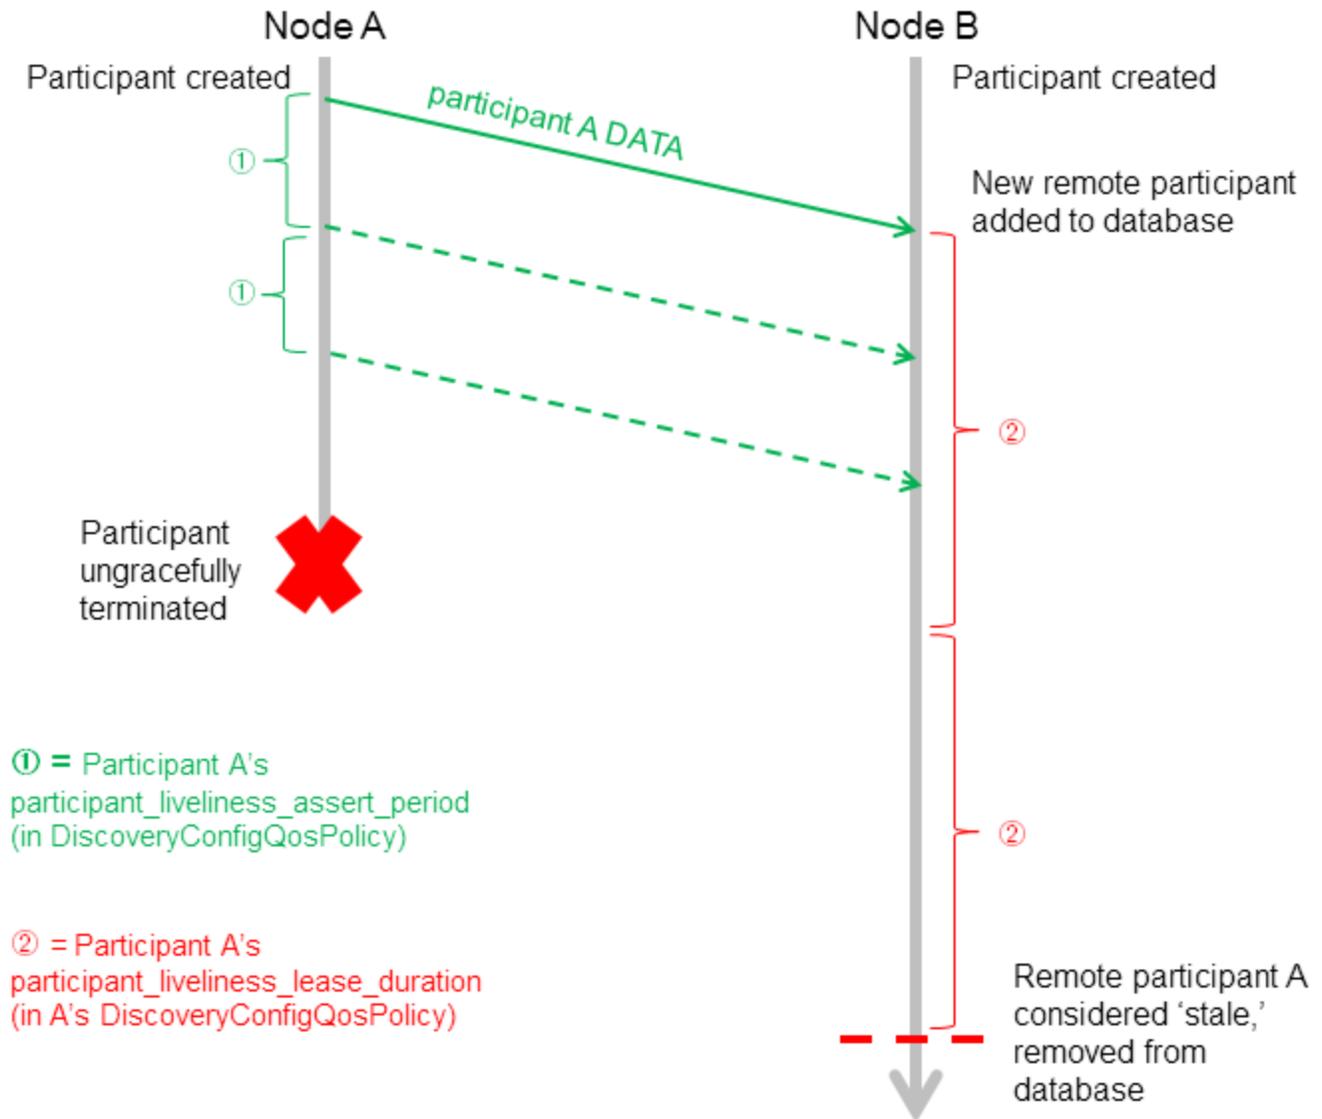

The `DomainParticipant` on Node A sends a 'participant DATA' to Node B, which is in Node A's peers list. This occurs regardless of whether or not there is a `Connex` application on Node B.

① The green short dashed lines are periodic participant DATAs. The time between these messages is controlled by the `participant_liveliness_assert_period` in the `DiscoveryConfig QosPolicy`.

k In addition to the periodic participant DATAs, 'initial repeat messages' (shown in blue, with longer dashes) are sent from A to B. These messages are sent at a random time between `min_initial_participant_announcement_period` and `max_initial_participant_announcement_period` (in A's `DiscoveryConfig QosPolicy`). The number of these initial repeat messages is set in `initial_participant_announcements`.

Figure 25.3: Ungraceful Termination of a Participant

Participant A is removed from participant B's database if it is not refreshed within the liveliness lease duration. Dashed lines are periodic participant DATA messages.

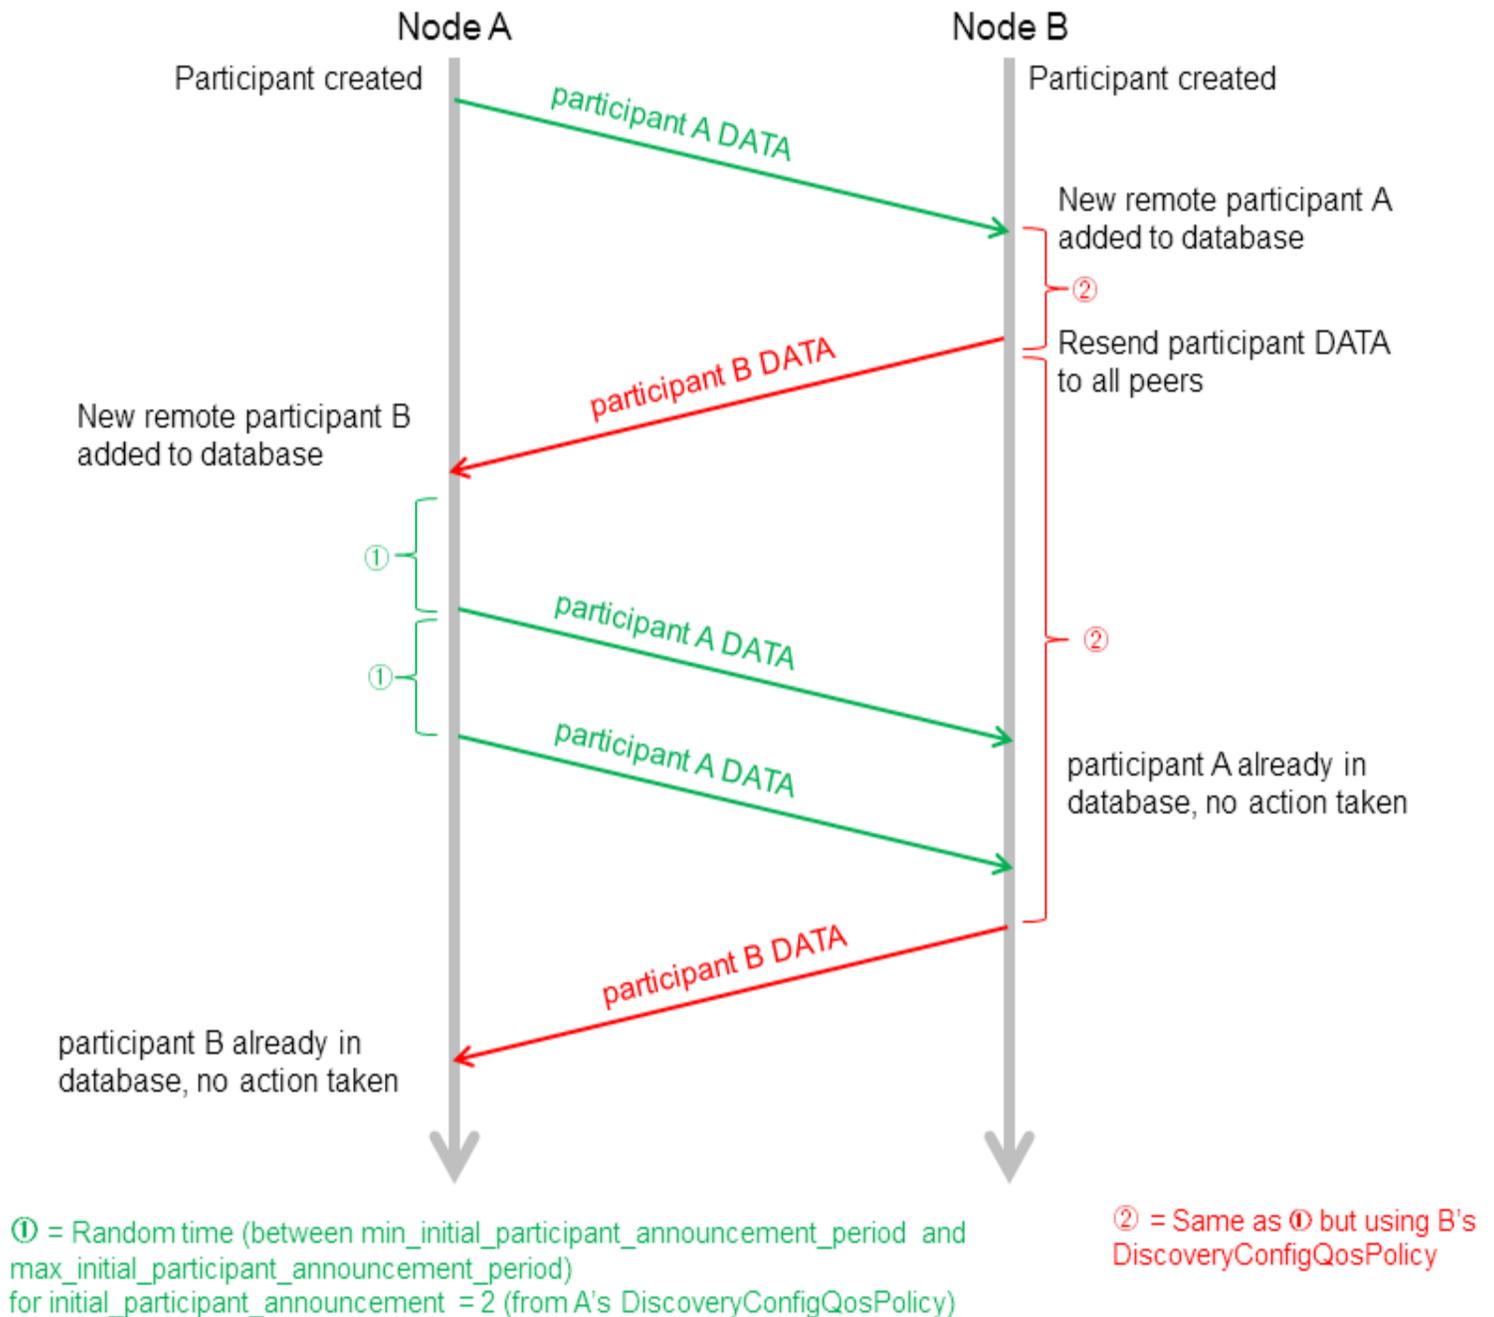

(Periodic resends of 'participant B DATA' from B to A are omitted from this diagram for simplicity. Initial repeat messages from A to B are also omitted from this diagram—these messages are sent at a random time between `min_initial_participant_announcement_period` and `max_initial_participant_announcement_period`, see Figure 25.2: Periodic 'participant DATAs' on the previous page.)

## 25.1.1 Refresh Mechanism

To ensure that a late-joining participant does not need to wait until the next refresh of the remote *participant DATA* to discover the remote participant, there is a resend mechanism. If the received *participant DATA* is from a never-before-seen remote participant, and it is in the local participant's peers list, the application will resend its own *participant DATA* to *all its peers*. This resend can potentially be done multiple times, with a random sleep time in between. [Figure 25.4: Resending 'participant DATA' to a Late-Joiner on the next page](#) illustrates this scenario.

The number of retries and the random amount of sleep between them are controlled by each participant's [44.3 DISCOVERY\\_CONFIG QosPolicy \(DDS Extension\) on page 703](#) (see [Figure 25.4: Resending 'participant DATA' to a Late-Joiner on the next page](#)).

Figure 25.4: Resending 'participant DATA' to a Late-Joiner

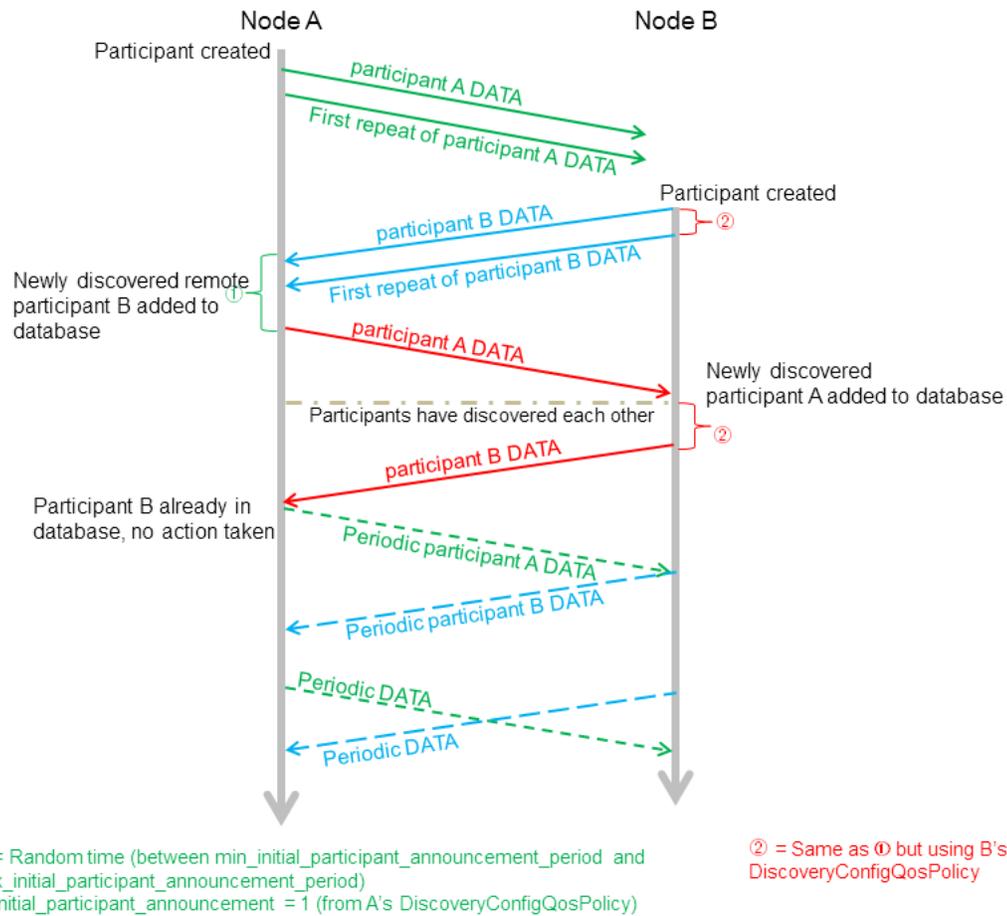

*Participant A has Participant B in its peers list. Participant B does not have Participant A in its peers list, but `[DiscoveryQosPolicy.accept_unknown_peers]` is set to `DDS_BOOLEAN_TRUE`. Participant A joins the system after B has sent its initial announcement. After B discovers A, it waits for time  $\Delta$ , then resends its participant DATA.*

(Initial repeat messages are omitted from this diagram for simplicity, see [Figure 25.2: Periodic 'participant DATAs' on page 334.](#))

**Figure 25.5: Participant Discovery Summary** below provides a summary of the messages sent during the participant discovery phase.

**Figure 25.5: Participant Discovery Summary**

Participants A and B both have each other in their peers lists. Participant A is created first.

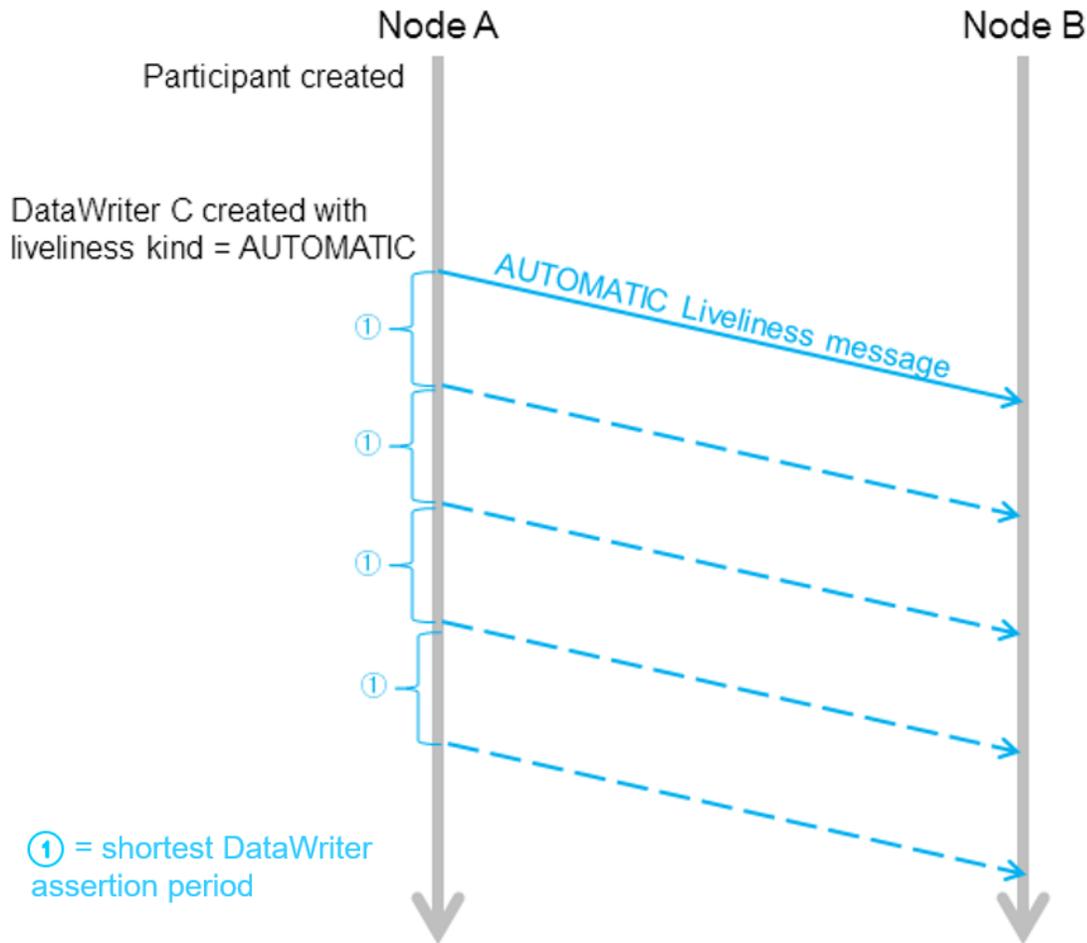

## 25.1.2 Maintaining DataWriter Liveliness for kinds AUTOMATIC and MANUAL\_BY\_PARTICIPANT

To maintain the liveliness of *DataWriters* that have a [47.15 LIVELINESS QoS Policy on page 825](#) **kind** field set to **AUTOMATIC** or **MANUAL\_BY\_PARTICIPANT**, *Connex* uses a built-in *DataWriter* and *DataReader* pair, referred to as the *inter-participant reader* and *inter-participant writer*.

If the *DomainParticipant* has any *DataWriters* with Liveliness QoS Policy **kind** set to **AUTOMATIC**, the inter-participant writer will reliably broadcast an **AUTOMATIC** Liveliness message at a period equal to X, where X is the shortest assertion period of these *DataWriters*. (The assertion period for a

*DataWriter* is calculated as **lease\_duration** / **assertions\_per\_lease\_duration**, which are fields in the 47.15 LIVELINESS QoSPolicy on page 825.) Figure 25.6: DataWriter with AUTOMATIC Liveliness below illustrates this scenario.

Figure 25.6: DataWriter with AUTOMATIC Liveliness

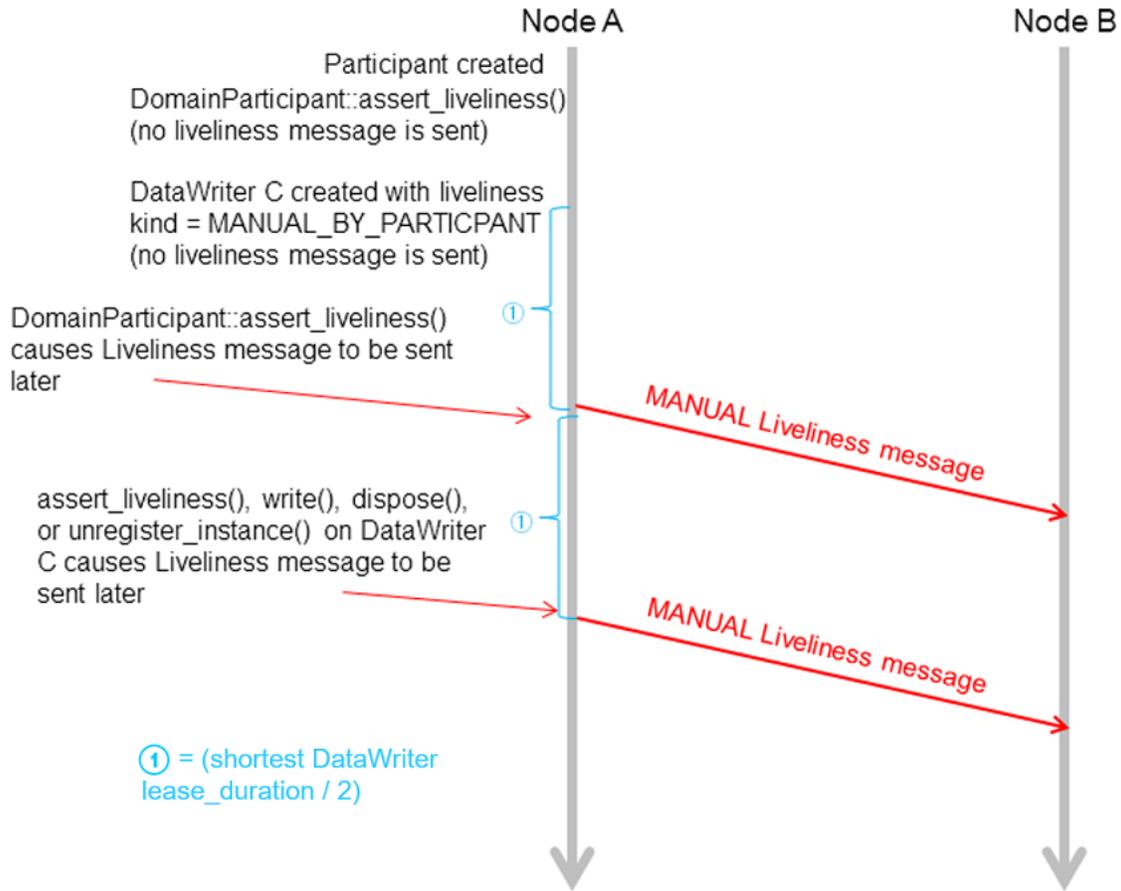

*A Liveliness message is sent automatically when a DataWriter with AUTOMATIC Liveliness kind is created, and then periodically.*

If the *DomainParticipant* has any *DataWriters* with Liveliness QoSPolicy **kind** set to **MANUAL\_BY\_PARTICIPANT**, *Connex* will periodically check to see if any of them have called **write()**, **assert\_liveliness()**, **dispose()** or **unregister()**. The rate of this check is every  $X/2$  seconds, where  $X$  is the smallest **lease\_duration** among all the *DomainParticipant's* **MANUAL\_BY\_PARTICIPANT** *DataWriters*. (The **lease\_duration** is a field in the 47.15 LIVELINESS QoSPolicy on page 825.) If any of the

**MANUAL\_BY\_PARTICIPANT** *DataWriters* have called any of those operations, the inter-participant writer will reliably broadcast a **MANUAL** Liveliness message.

If a *DomainParticipant's* **assert\_liveliness()** operation is called, and that *DomainParticipant* has any **MANUAL\_BY\_PARTICIPANT** *DataWriters*, the inter-participant writer will reliably broadcast a **MANUAL** Liveliness message within the above-defined X/2 time period. These **MANUAL** Liveliness messages are used to update the liveliness of all the *DomainParticipant's* **MANUAL\_BY\_PARTICIPANT** *DataWriters*. As described in [47.15.1 Timing Considerations for MANUAL\\_BY\\_PARTICIPANT on page 828](#), *Connex* applications should make sure to assert liveliness at a period that is shorter than half of the minimum lease duration; otherwise, liveliness might be lost for the *DataWriter*. [Figure 25.7: DataWriter with MANUAL\\_BY\\_PARTICIPANT Liveliness below](#) shows an example sequence.

Figure 25.7: DataWriter with MANUAL\_BY\_PARTICIPANT Liveliness

Once a **MANUAL\_BY\_PARTICIPANT** *DataWriter* is created, subsequent calls to **assert\_liveliness**, **write**, **dispose**, or **unregister\_instance** will trigger Liveliness messages, which update the liveliness status of all the participant's *DataWriters*.

The inter-participant reader receives data from remote inter-participant writers and asserts the liveness of remote *DomainParticipants* endpoints accordingly.

If the *DomainParticipant* has no *DataWriters* with [47.15 LIVELINESS QoS Policy on page 825](#) kind set to **AUTOMATIC** or **MANUAL\_BY\_PARTICIPANT**, then no Liveness messages are ever sent from the inter-participant writer.

## 25.2 Endpoint Discovery

As we saw in [Figure 25.1: Built-in Writers and Readers for Discovery on page 332](#), reliable *DataReaders* and *DataWriters* are automatically created to exchange publication/subscription information for each *DomainParticipant*. We will refer to these as ‘discovery endpoint readers and writers.’ However, nothing is sent through the network using these entities until they have been ‘matched’ with their remote counterparts. This ‘matching’ is triggered by the Participant Discovery phase. The goal of the Endpoint Discovery phase is to add the remote endpoint to the local database, so that user-created endpoints (your application’s *DataWriters/DataReaders*) can communicate with each other.

When a new remote *DomainParticipant* is discovered and added to a participant’s database, *Connex* assumes that the remote *DomainParticipant* is implemented in the same way and therefore is creating the appropriate counterpart entities. Therefore, *Connex* will automatically add two remote discovery endpoint readers and two remote discovery endpoint writers for that remote *DomainParticipant* into the local database. Once that is done, there is now a match with the local discovery endpoint writers and readers, and *publication DATAs* and *subscription DATAs* can then be sent between the discovery endpoint readers/writers of the two *DomainParticipant*.

When you create a *DataWriter/DataReader* for your user data, a *publication/subscription DATA* describing the newly created object is sent from the local discovery endpoint writer to the remote discovery endpoint readers of the remote *DomainParticipants* that are currently in the local database.

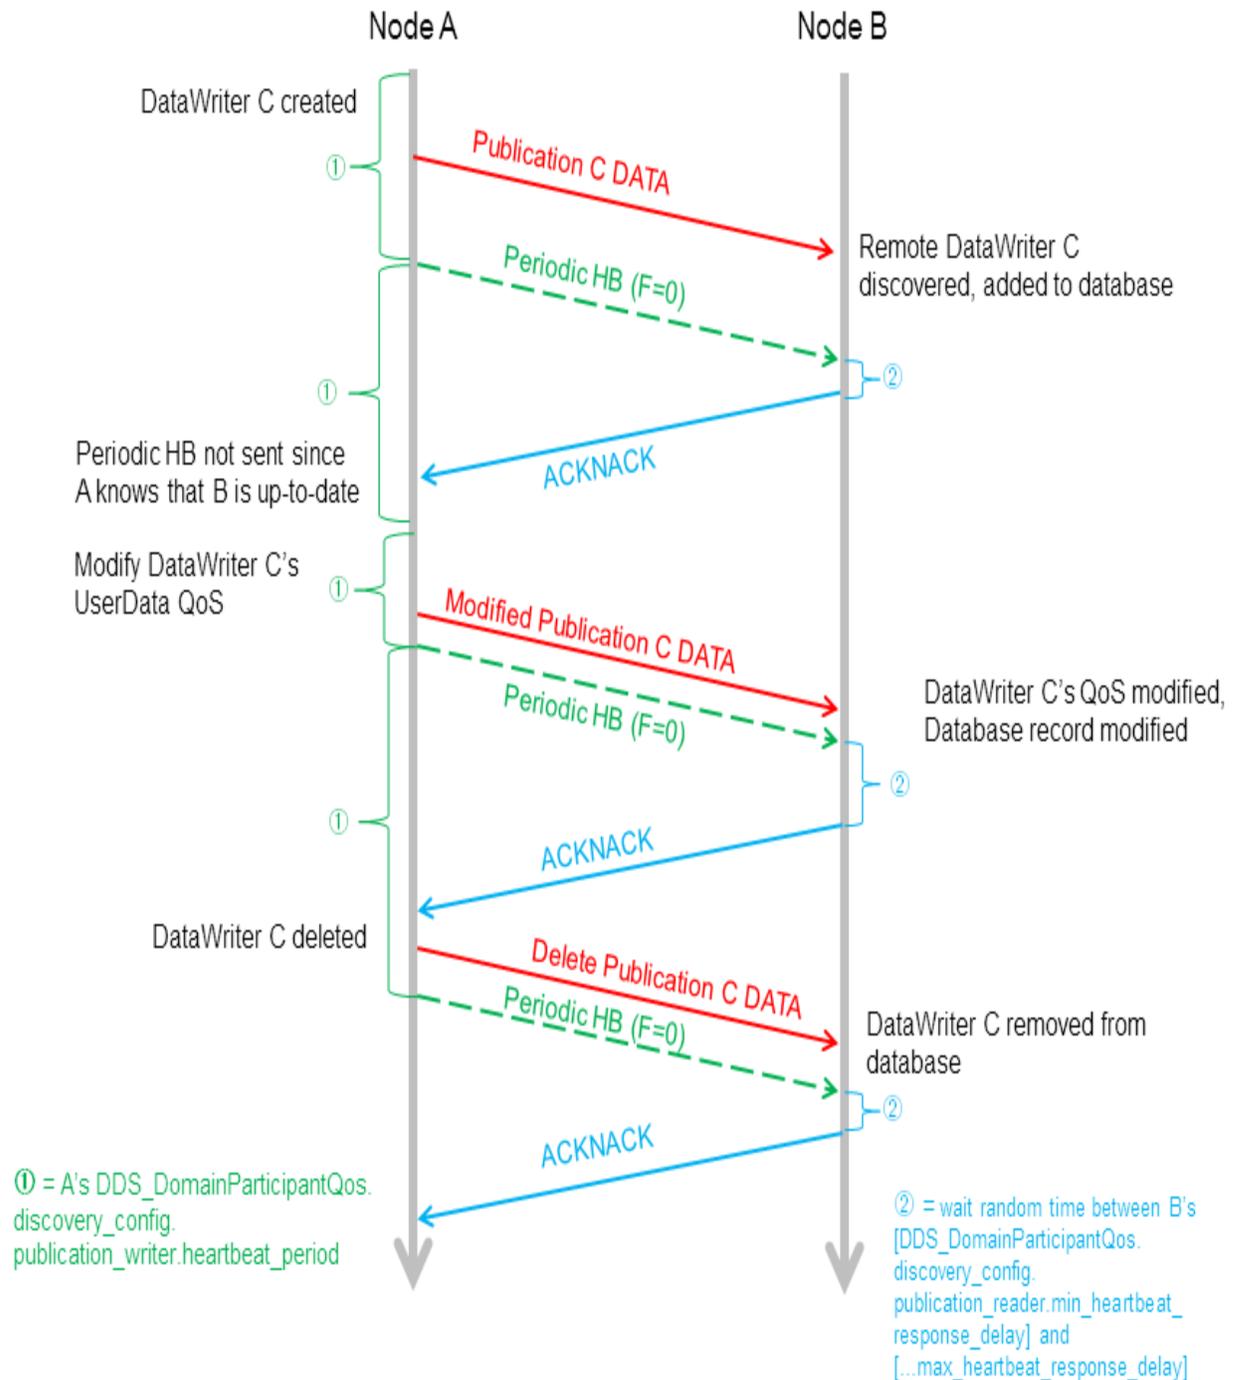

If your application changes any of the following QoS Policies for a local user-data *DataWriter/DataReader*, a modified *subscription/publication DATA* is sent to propagate the QoS change to other *DomainParticipants*:

- [45.1 TOPIC\\_DATA QoS Policy on page 737](#)
- [46.4 GROUP\\_DATA QoS Policy on page 748](#)
- [47.30 USER\\_DATA QoS Policy on page 864](#)
- [47.18 OWNERSHIP\\_STRENGTH QoS Policy on page 836](#)
- [46.5 PARTITION QoS Policy on page 751](#)
- [48.4 TIME\\_BASED\\_FILTER QoS Policy on page 888](#)
- [47.14 LIFESPAN QoS Policy on page 824](#)

What the above QosPolicies have in common is that they are all changeable and part of the built-in data (see [Accessing Discovery Information through Built-In Topics \(Chapter 28 on page 359\)](#)).

Similarly, if the application deletes any user-data writers/readers, the discovery endpoint writer/readers send *delete publication/subscription DATAs*. In addition to sending *publication/subscription DATAs*, the discovery endpoint writer will check periodically to see if the remote discovery endpoint reader is up-to-date. (The rate for this check is the `publication_writer.heartbeat_period` or `subscription_writer.heartbeat_period` in the [44.3 DISCOVERY\\_CONFIG QosPolicy \(DDS Extension\) on page 703](#). If the discovery endpoint writer has not been acknowledged by the remote discovery endpoint reader regarding receipt of the latest DATA, the discovery endpoint writer will send a special Heartbeat (HB) message with the Final bit set to 0 (F=0) to request acknowledgement from the remote discovery endpoint reader, as seen in [Figure 25.8: Endpoint Discovery Summary on the next page](#).

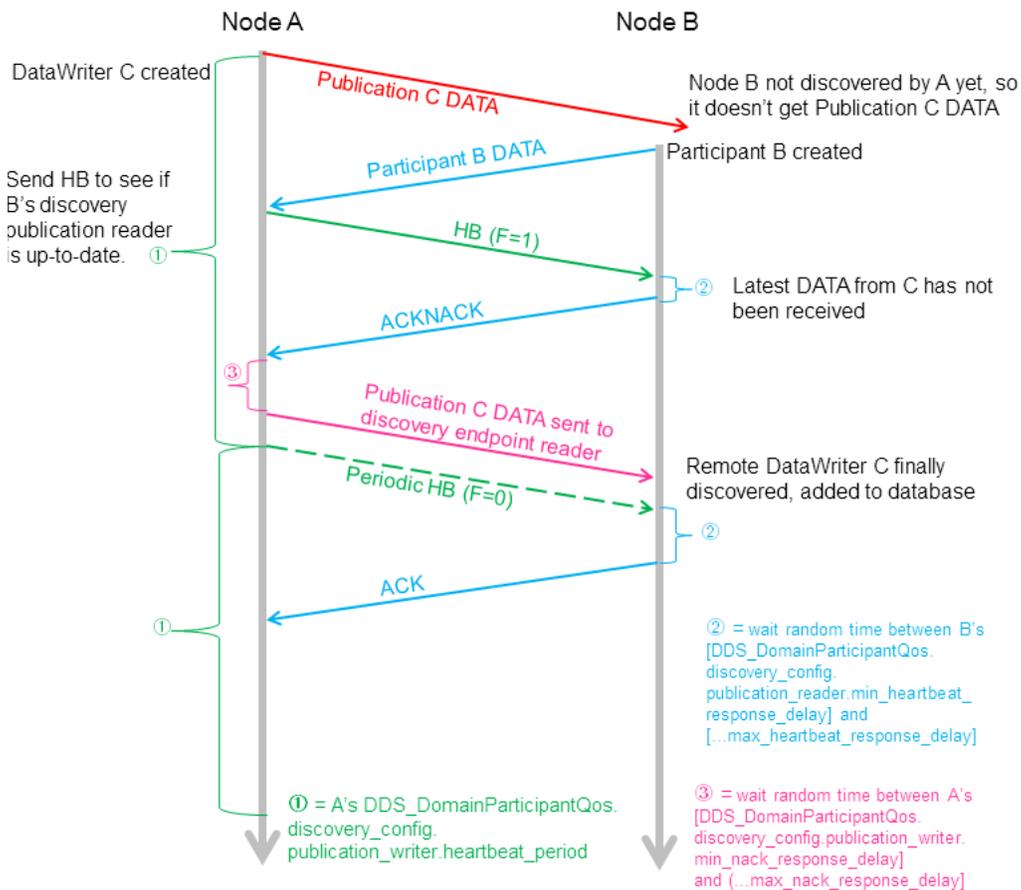

Figure 25.8: Endpoint Discovery Summary

Assume participants A and B have been discovered on both sides. A's `DiscoveryConfigQosPolicy.publication_writer.heartbeats_per_max_samples = 0`, so no HB is piggybacked with the publication DATA. A HB with `F=0` is a request for an ACK/NACK. The periodic and initial repeat participant DATAs are omitted from the diagram.

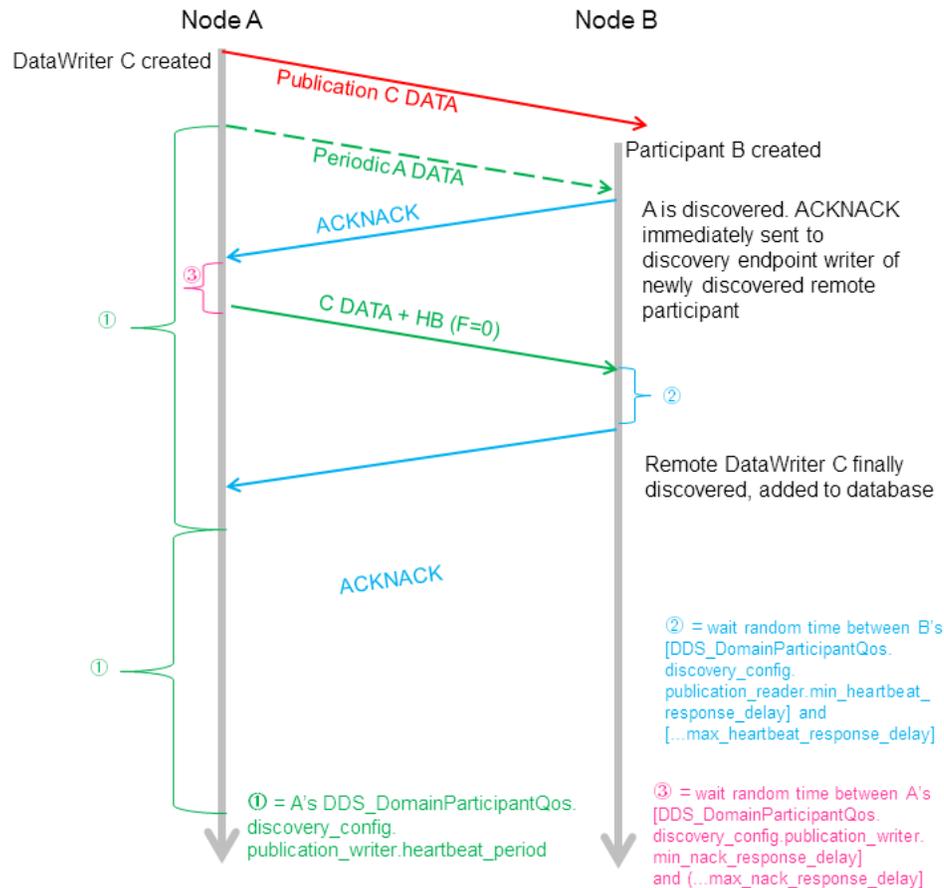

Discovery endpoint writers and readers have their [47.12 HISTORY QoS Policy on page 818](#) set to KEEP\_LAST, and their [47.9 DURABILITY QoS Policy on page 809](#) set to TRANSIENT\_LOCAL. Therefore, even if the remote *DomainParticipant* has not yet been discovered at the time the local user's *DataWriter/DataReader* is created, the remote *DomainParticipant* will still be informed about the previously created *DataWriter/DataReader*. This is achieved by the HB and ACK/NACK that are immediately sent by the built-in endpoint writer and built-in endpoint reader respectively when a new remote participant is discovered. [Figure 25.9: DataWriter Discovered by Late-Joiner, Triggered by HB below](#) and [Figure 25.10: DataWriter Discovered by Late-Joiner, Triggered by ACKNACK on the next page](#) illustrate this sequence for HB and ACK/NACK triggers, respectively.

**Figure 25.9: DataWriter Discovered by Late-Joiner, Triggered by HB**

Writer C is created on Participant A before Participant A discovers Participant B. Assuming `DiscoveryConfigQoSPolicy.publication_writer.heartbeats_per_max_samples = 0`, no HB is piggybacked with the publication DATA. Participant B has A in its peer list, but not vice versa. `Accept_unknown_locators` is true. On A, in response to receiving the new participant B DATA message, a participant A DATA message is sent to B. The discovery endpoint reader on A will also send an ACK/NACK to the discovery endpoint writer on B. (Initial repeat participant messages and periodic participant messages are omitted from this diagram for simplicity, see [Figure 25.2: Periodic 'participant DATAs' on page 334 in 25.1 Participant Discovery on page 332.](#))

Figure 25.10: DataWriter Discovered by Late-Joiner, Triggered by ACKNACK

Writer C is created on Participant A before Participant A discovers Participant B. Assuming `DiscoveryConfigQosPolicy.publication_writer.heartbeats_per_max_samples = 0`, no HB is piggybacked with the publication DATA message. Participant A has B in its peer list, but not vice versa. `Accept_unknown_locators` is true. In response to receiving the new Participant A DATA message on node B, a participant B DATA message will be sent to A. The discovery endpoint writer on Node B will also send a HB to the discovery endpoint reader on Node A. These are omitted in the diagram for simplicity. (Initial repeat participant messages and periodic participant messages are omitted from this diagram, see [Figure 25.2: Periodic 'participant DATAs'](#) on page 334 in [25.1 Participant Discovery](#) on page 332.)

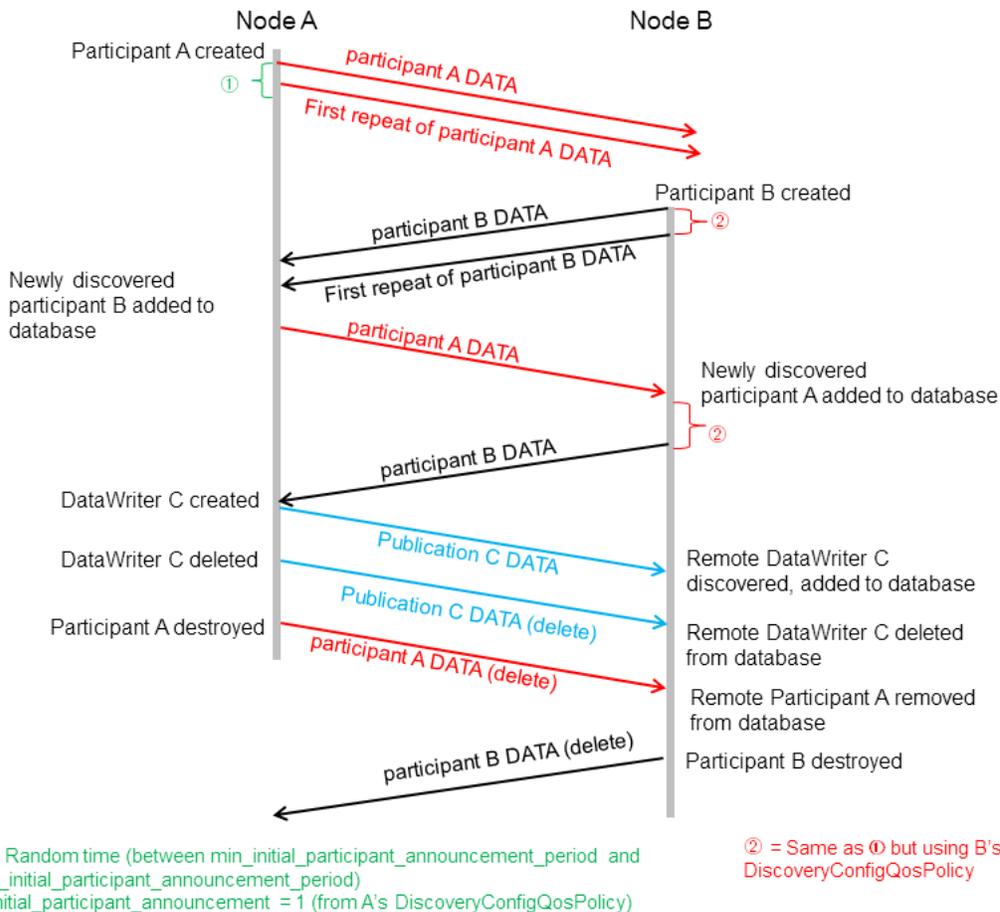

Endpoint discovery latency is determined by the following members of the `DomainParticipant's` [44.3 DISCOVERY\\_CONFIG QosPolicy \(DDS Extension\)](#) on page 703:

- **publication\_writer**
- **subscription\_writer**
- **publication\_reader**
- **subscription\_reader**

When a remote entity record is added, removed, or changed in the database, matching is performed with all the local entities. Only after there is a successful match on both ends can an application's user-created *DataReaders* and *DataWriters* communicate with each other.

For more information about reliable communication, see [Reliability Models for Sending Data \(Chapter 32 on page 446\)](#).

## 25.3 Discovery Traffic Summary

*This diagram shows both phases of the discovery process. Participant A is created first, followed by Participant B. Each has the other in its peers list. After they have discovered each other, a DataWriter is created on Participant A. Periodic participant DATAs, HBs and ACK/NACKs are omitted from this diagram.*

## 25.4 Discovery-Related QoS

Each *DomainParticipant* needs to be uniquely identified in the DDS domain and specify which other *DomainParticipants* it is interested in communicating with. The [44.9 WIRE\\_PROTOCOL QoSPolicy \(DDS Extension\) on page 730](#) uniquely identifies a *DomainParticipant* in the DDS domain. The [44.2](#)

[DISCOVERY QosPolicy \(DDS Extension\) on page 699](#) specified the peer participants it is interested in communicating with.

There is a trade-off between the amount of traffic on the network for the purposes of discovery and the delay in reaching steady state when the *DomainParticipant* is first created.

For example, if the [44.2 DISCOVERY QosPolicy \(DDS Extension\) on page 699](#)'s `participant_liveliness_assert_period` and `participant_liveliness_lease_duration` fields are set to small values, the discovery of stale remote *DomainParticipants* will occur faster, but more discovery traffic will be sent over the network. Setting the participant's `heartbeat_period`<sup>1</sup> to a small value can cause late-joining *DomainParticipants* to discover remote user-data *DataWriters* and *DataReaders* at a faster rate, but *Connex*t might send HBs to other nodes more often. This timing can be controlled by the following *DomainParticipant* QosPolicies:

- [44.2 DISCOVERY QosPolicy \(DDS Extension\) on page 699](#) — specifies how other *DomainParticipants* in the network can communicate with this *DomainParticipant*, and which other *DomainParticipants* in the network this *DomainParticipant* is interested in communicating with. See also: [Chapter 23 Ports Used for Discovery on page 319](#).
- [44.3 DISCOVERY\\_CONFIG QosPolicy \(DDS Extension\) on page 703](#) — specifies the QoS of the discovery readers and writers (parameters that control the HB and ACK rates of discovery endpoint readers/writers, and periodic refreshing of *participant DATA* from discovery participant readers/writers). It also allow you to configure asynchronous writers in order to send data with a larger size than the transport message size.
- [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 714](#) — specifies the number of local and remote entities expected in the system.
- [44.9 WIRE\\_PROTOCOL QosPolicy \(DDS Extension\) on page 730](#) — specifies the `rtps_app_id` and `rtps_host_id` that uniquely identify the participant in the DDS domain.

The other important parameter is the domain ID: *DomainParticipants* can only discover each other if they belong to the same DDS domain. The domain ID is a parameter passed to the `create_participant()` operation (see [16.3.1 Creating a DomainParticipant on page 87](#)).

## 25.5 Debugging Discovery

For information on debugging discovery, see [Troubleshooting Discovery \(Chapter 55 on page 1117\)](#).

---

<sup>1</sup>`heartbeat_period` is part of the `DDS_RtpsReliableWriterProtocol_t` structure used in the [44.2 DISCOVERY QosPolicy \(DDS Extension\) on page 699](#)'s `publication_writer` and `subscription_writer` fields.

# Chapter 26 Discovered RTPS Locators and Changes with IP Mobility

DDS endpoints (*DataWriters* and *DataReaders*) can be reached at specific transport addresses called RTPS locators. An RTPS locator is an n-tuple (transport, address, port). For example (UDPv4, 192.168.1.1, 7400) is a locator for the UDPv4 transport. Locator information is sent as part of the Participant and Endpoint DATA messages (see [Discovery Overview \(Chapter 22 on page 309\)](#)).

The initial set of locators that a *DomainParticipant* will use to communicate with other *DomainParticipants* is provided using a peer descriptor (see [Chapter 24 Configuring the Peers List Used in Discovery on page 324](#)).

## 26.1 Locator Changes at Run Time

In *Connex* 5.2.3 and earlier, the set of locators associated with a DDS endpoint could not be changed after the *DomainParticipant* containing the endpoints was enabled. Therefore, *Connex* was not prepared to deal with, for example, IP address changes in IP-based transports.

Starting with *Connex* 5.3.0, locator changes are propagated as part of new Participant and Endpoint DATA messages.

### 26.1.1 Locator Changes in IP-Based Transports

For IP-based transports, including UDPv4 and UDPv6, the following IP mobility use cases (i.e., the need for IP-address changes at runtime) are supported in *Connex* 5.3.0 and higher:

- Starting a *DomainParticipant* without network connectivity and connecting to the network at runtime.
- Switching network interfaces (for example, going from wired to Wi-Fi).

- Acquiring a new IP address after DHCP lease expiration.
- Having mobile devices roaming across network segments.

*Connex* supports IP mobility in all IP-based transports.

The functionality is enabled out-of-the-box.

When possible, the detection of IP address changes is done asynchronously using the APIs offered by the underlying OS. If there is no mechanism to do that, the detection will use a polling strategy.

The polling period can be configured using the following transport property in the *DomainParticipant's* *PropertyQosPolicy*: `<<transport prefix>>.interface_poll_period`. For example, for UDPv4 the property name is `dds.transport.UDPv4.builtin.interface_poll_period`.

### 26.1.1.1 Starting a DomainParticipant without Enabled Network Interfaces

For this use case, the GUID prefix generation algorithm must not be based on the IPv4/MAC address of the first enabled interface, but must use a UUID algorithm instead. This is necessary to avoid collisions on the GUID, which needs to be unique on the network.

In *Connex* 5.3.x, to enable the use of a UUID algorithm to generate the GUID, you had to modify the `rtps_auto_id_kind` field in the *DomainParticipant's* [44.9 WIRE\\_PROTOCOL QosPolicy \(DDS Extension\) on page 730](#) to `DDS RTPS_AUTO_ID_FROM_UUID`. Starting with *Connex* 6.0.0, the default value of this field changed to `DDS RTPS_AUTO_ID_FROM_UUID`, and you do not need to modify it.

### 26.1.1.2 Disabling IP Locator Change Propagation

*Connex* 5.2.3 and earlier will report errors if it detects locator changes in a DDS endpoint. You can disable the notification and propagation of these changes for a *DomainParticipant*. This way, an interface change in a 5.3.0 or higher application will not trigger errors in an application running 5.2.3 or earlier. Setting this property to true will prevent a 5.3.0 application from being able to detect network interface changes.

To disable the notification of IP locator changes, set the following transport property in the *DomainParticipant's* *PropertyQosPolicy*: `<<transport prefix>>.disable_interface_tracking`. For example, for UDPv4 the property name is `dds.transport.UDPv4.builtin.disable_interface_tracking`. To disable the property in XML, for example:

```
<domain_participant_qos>
  <property>
    <value>
      <element>
        <name>dds.transport.UDPv4.builtin.disable_interface_tracking</name>
        <value>true</value>
      </element>
    </value>
```

```
</property>
</domain_participant_qos>
```

## 26.2 Detection of Unreachable Locators

It is possible for a *DomainParticipant* to announce locators for endpoints that are temporarily or permanently unreachable from a different *DomainParticipant*.

For example, *DomainParticipant* 'A' may send to a different *DomainParticipant* 'B' one locator where the IP address corresponds to a subnet that is not reachable from *DomainParticipant* 'B'. In such case, the *DomainParticipant* 'B' running in a different subnet should not use this address to send information to the endpoints of *DomainParticipant* 'A'.

In *Connex* 5.2.3 and earlier, the middleware did not have the ability to detect unreachable locators. This had two main consequences:

1. The middleware could waste CPU cycles and bandwidth sending messages to unreachable locators.
2. If the unreachable locator was a multicast locator, the destination endpoint would never receive live samples from the sender's endpoints. For best-effort communication, this would have resulted in never receiving samples. For reliable communication, this would have resulted in sending samples as repair traffic.

*Connex* 5.3.0 introduces a new locator REACHABILITY PING mechanism, which the middleware can use to detect when an endpoint is not reachable at a locator; then it can stop using the locator to send data to the endpoint. For temporary disconnections, the middleware will be able to detect and use an endpoint's locator that becomes reachable again. While data is not being sent to an unreachable locator, the middleware still sends periodic REACHABILITY PING messages to see if it is still unreachable.

The configuration of the REACHABILITY mechanism is done using the following *DomainParticipant's* QoSPolicy values:

- **participant\_qos.discovery\_config.locator\_reachability\_assert\_period**
- **participant\_qos.discovery\_config.reachability\_lease\_duration**
- **participant\_qos.discovery\_config.locator\_reachability\_change\_detection\_period**

For more information on these QoS values, see [Table 44.3 DDS\\_DiscoveryConfigQoSPolicy](#).

## 26.3 Using DNS Tracker to Keep Peer List Updated

*Connex* allows the use of hostnames instead of IP addresses when configuring peers for specific transports (e.g., UDPv4 and UDPv6). By default, *Connex* resolves hostnames into IP addresses only when the *DomainParticipant* is created. But you can use the DNS tracker to keep the IP addresses of these

hostnames updated. The DNS tracker does this by creating a thread that regularly polls the DNS service. This thread detects changes in the IP address that a hostname is resolved to and updates the related peers accordingly.

Use the **dns\_tracker\_polling\_period** field in the [44.3 DISCOVERY\\_CONFIG QosPolicy \(DDS Extension\) on page 703](#) to define how often the DNS tracker thread will query the DNS service for updates (e.g., every 30 seconds). When the period is set to `DDS_DURATION_INFINITE` (the default value), the tracker is disabled and changes in hostnames will not be tracked. You can also configure the polling period after the creation of the *DomainParticipant* using the *DomainParticipant*'s **set\_dns\_tracker\_polling\_period()** operation. This operation can enable or disable the DNS tracker depending on the value of the **DDS\_Duration\_t** provided as parameter.

*Connex*t keeps information regarding the hostnames of peers, whether the hostnames are part of the **initial\_peers** field in the [44.2 DISCOVERY QosPolicy \(DDS Extension\) on page 699](#) or the peers were added through the *DomainParticipant*'s **add\_peer()** API. When the DNS tracker is enabled, it builds the list of names to track from the *DomainParticipant*'s current peers. Removing peers from the *DomainParticipant* (using the **remove\_peer()** API) will also affect the DNS tracker. If all the peers with a specific name are removed, the DNS tracker will stop tracking that name.

Enabling the DNS tracker changes the behavior of the *DomainParticipant*'s **add\_peer()** API. If the DNS tracker has not been enabled, the API will fail to add a peer with a hostname that cannot be resolved into an IP address. If the DNS tracker has been enabled, the *DomainParticipant*'s **add\_peer()** API will successfully add a peer with a hostname that cannot be resolved into an IP address. Although the hostname or the DNS service may not be available when the **add\_peer()** API is called, the enabled DNS tracker will be able to resolve the name and update the locator once the hostname can be resolved.

Once the DNS tracker has been enabled, the change in the behavior of the *DomainParticipant*'s **add\_peer()** API remains until the *DomainParticipant* is destroyed. Adding a peer with a hostname that cannot be resolved will not produce an error even if the DNS tracker is disabled. *Connex*t assumes that if the DNS tracker has been enabled once, all hostnames should be considered as valid peers independently of the status of the DNS tracker at the moment of adding the peer.

## Chapter 27 Restricting Communication— Ignoring Entities

The **ignore\_participant()** operation allows an application to ignore all communication from a specific *DomainParticipant*. Or for even finer control you can use the **ignore\_publication()**, **ignore\_subscription()**, and **ignore\_topic()** operations. These operations are described below.

```
DDS_ReturnCode_t ignore_participant (const DDS_InstanceHandle_t &handle)
DDS_ReturnCode_t ignore_publication (const DDS_InstanceHandle_t &handle)
DDS_ReturnCode_t ignore_subscription (const DDS_InstanceHandle_t &handle)
DDS_ReturnCode_t ignore_topic (const DDS_InstanceHandle_t &handle)
```

The entity to ignore is identified by the *handle* argument. It may be a local or remote entity. For **ignore\_publication()**, the handle will be that of a local *DataWriter* or a discovered remote *DataWriter*. For **ignore\_subscription()**, that handle will be that of a local *DataReader* or a discovered remote *DataReader*.

The safest approach for ignoring an entity is to call the ignore operation within the *Listener* callback of the built-in reader, or before any local entities are enabled. This will guarantee that the local entities (entities that are created by the local *DomainParticipant*) will never have a chance to establish communication with the remote entities (entities that are created by another *DomainParticipant*) that are going to be ignored.

If the above is not possible and a remote entity is to be ignored after the communication channel has been established, the remote entity will still be removed from the database of the local application as if it never existed. However, since the remote application is not aware that the entity is being ignored, it may potentially be expecting to receive messages or continuing to send messages. Depending on the QoS of the remote entity, this may affect the behavior of the remote application and may potentially stop the remote application from communicating with other entities.

You can use this operation in conjunction with the *ParticipantBuiltinTopicData* to implement access control. You can pass application data associated with a *DomainParticipant* in the [47.30](#)

[USER\\_DATA QoSPolicy on page 864](#). This application data is propagated as a field in the built-in topic. Your application can use the data to implement an access control policy.

Ignore operations, in conjunction with the Built-in Topic Data, can be used to implement access control. You can pass data associated with an entity in the [47.30 USER\\_DATA QoSPolicy on page 864](#), [46.4 GROUP\\_DATA QoSPolicy on page 748](#) or [45.1 TOPIC\\_DATA QoSPolicy on page 737](#). This data is propagated as a field in the built-in topic. When data for a built-in topic is received, the application can check the `user_data`, `group_data` or `topic_data` field of the remote entity, determine if it meets the security requirement, and ignore the remote entity if necessary.

See also: [Discovery Overview \(Chapter 22 on page 309\)](#). See also: [16.3.5 Isolating DomainParticipants and Endpoints from Each Other on page 91](#).

## 27.1 Ignoring Specific Remote DomainParticipants

The `ignore_participant()` operation is used to instruct *Connex* to locally ignore a remote *DomainParticipant*. It causes *Connex* to locally behave as if the remote *DomainParticipant* does not exist.

```
DDS_ReturnCode_t ignore_participant (const DDS_InstanceHandle_t & handle)
```

After invoking this operation, *Connex* will locally ignore any *Topic*, *publication*, or *subscription* that originates on that *DomainParticipant*. (If you only want to ignore specific publications or subscriptions, see [27.2 Ignoring Publications and Subscriptions on the next page](#) instead.) [Figure 27.1: Ignoring Participants below](#) provides an example.

By default, the maximum number of participants that can be ignored is limited by `ignored_entity_allocation.max_count` in the [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QoSPolicy \(DDS Extension\) on page 714](#). However, that behavior can be changed by using `ignore_entity_replacement_kind` in the same QoS policy.

**See also:** [27.4 Resource Limits Considerations for Ignored Entities on page 356](#).

**Caution:** There is no way to reverse this operation. You can add to the peer list, however—see [44.2.3 Adding and Removing Peers List Entries on page 700](#).

**Figure 27.1: Ignoring Participants**

```
class MyParticipantBuiltinTopicDataListener :
public DDSDataReaderListener {
    public:
        virtual void on_data_available(DDSDataReader *reader);
        // .....
};

void MyParticipantBuiltinTopicDataListener::on_data_available(
    DDSDataReader *reader) {
    DDSParticipantBuiltinTopicDataDataReader
        *builtinTopicDataReader =
        DDSParticipantBuiltinTopicDataDataReader *) reader;
    DDS_ParticipantBuiltinTopicDataSeq data_seq;
    DDS_SampleInfoSeq info_seq;
    int = 0;
```

```

if (builtinTopicDataReader->take(data_seq, info_seq,
    DDS_LENGTH_UNLIMITED, DDS_ANY_SAMPLE_STATE,
    DDS_ANY_VIEW_STATE, DDS_ANY_INSTANCE_STATE) !=
    DDS_RETCODE_OK){
    // ... error
}
for (i = 0; i < data_seq.length(); ++i) {
    if (info_seq[i].valid_data) {
        // check user_data for access control
        if (data_seq[i].user_data[0] != 0x9) {
            if (builtinTopicDataReader->get_subscriber()
                ->get_participant()
                ->ignore_participant(
                    info_seq[i].instance_handle)
                != DDS_RETCODE_OK) {
                // ... error
            }
        }
    }
}
if (builtinTopicDataReader->return_loan(
    data_seq, info_seq) != DDS_RETCODE_OK) {
    // ... error
}
}

```

## 27.2 Ignoring Publications and Subscriptions

You can instruct *Connex*t to locally ignore a publication or subscription. A publication/subscription is defined by the association of a *Topic* name, user data and partition set on the *Publisher/Subscriber*. After this call, any data written related to associated *DataWriter/DataReader* will be ignored.

The entity to ignore is identified by the **handle** argument. For **ignore\_publication()**, the handle will be that of a *DataWriter*. For **ignore\_subscription()**, that handle will be that of a *DataReader*.

This operation can be used to ignore local *and* remote entities:

- For local entities, you can obtain the handle argument by calling the **get\_instance\_handle()** operation for that particular entity.
- For remote entities, you can obtain the handle argument from the `DDS_SampleInfo` structure retrieved when reading DDS data samples available for the entity's built-in *DataReader*.

```

DDS_ReturnCode_t ignore_publication (const DDS_InstanceHandle_t & handle)
DDS_ReturnCode_t ignore_subscription (const DDS_InstanceHandle_t & handle)

```

**Caution:** There is no way to reverse these operations.

Figure 27.2: Ignoring Publications on the next page provides an example.

Figure 27.2: Ignoring Publications

```

class MyPublicationBuiltinTopicDataListener : public DDSDataReaderListener
{
public:
    virtual void on_data_available(DDSDataReader *reader);
    // .....
};

void MyPublicationBuiltinTopicDataListener::on_data_available(
    DDSDataReader *reader) {
    DDSPublicationBuiltinTopicDataReader *builtinTopicDataReader =
        (DDS_PublicationBuiltinTopicDataReader *)reader;
    DDS_PublicationBuiltinTopicDataSeq data_seq;
    DDS_SampleInfoSeq info_seq;
    int = 0;
    if (builtinTopicDataReader->take(data_seq, info_seq,
        DDS_LENGTH_UNLIMITED, DDS_ANY_SAMPLE_STATE,
        DDS_ANY_VIEW_STATE, DDS_ANY_INSTANCE_STATE)
        != DDS_RETCODE_OK)
    {
        // ... error
    }
    for (i = 0; i < data_seq.length(); ++i) {
        if (info_seq[i].valid_data) {
            // check user_data for access control
            if (data_seq[i].user_data[0] != 0x9) {
                if (builtinTopicDataReader->get_subscriber()
                    ->get_participant()
                    ->ignore_publication(
                        info_seq[i].instance_handle)
                        != DDS_RETCODE_OK) {
                    // ... error
                }
            }
        }
    }
}

if (builtinTopicDataReader->return_loan(data_seq, info_seq) !=
    DDS_RETCODE_OK) {
    ...
}

```

## 27.3 Ignoring Topics

The **ignore\_topic()** operation instructs *Connex* to locally ignore a *Topic*. This means it will locally ignore any publication or subscription to the *Topic*.

```
DDS_ReturnCode_t ignore_topic (const DDS_InstanceHandle_t & handle)
```

**Caution:** There is no way to reverse this operation.

If you know that your application will never publish or subscribe to data under certain topics, you can use this operation to save local resources.

The *Topic* to ignore is identified by the handle argument. This handle is the one that appears in the `DDS_SampleInfo` retrieved when reading the DDS data samples from the built-in `DataReader` to the *Topic*.

## 27.4 Resource Limits Considerations for Ignored Entities

When an entity is ignored, *Connex* adds it to an internal ‘ignore’ table whose resource limits are configured using the `ignored_entity_allocation.max_count` in the [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QoS Policy \(DDS Extension\) on page 714](#). The behavior of *Connex* when this limit is exceeded can be modified by using the `ignored_entity_replacement_kind` in the same QoS policy.

The default value for `ignored_entity_replacement_kind` is `DDS_NO_REPLACEMENT_IGNORED_ENTITY_REPLACEMENT`, meaning that a call to the `DomainParticipant`’s `ignore_participant()`, `ignore_publication()`, or `ignore_subscription()` will fail if the *DomainParticipant* has ignored more entities than the limit set in `ignored_entity_allocation.max_count` entities.

When `ignored_entity_replacement_kind` is set to `DDS_NOT_ALIVE_FIRST_IGNORED_ENTITY_REPLACEMENT`, a call to `ignore_participant()` will not fail when `ignored_entity_allocation.max_count` is exceeded, as long as there is one *DomainParticipant* already ignored. Instead, the call will replace one of the existing *DomainParticipants* in the internal table. The remote *DomainParticipant* that will be replaced is the one for which the local *DomainParticipant* had not received any message for the longest time.

When a remote *DomainParticipant* is replaced in the ‘ignore’ table, it becomes un-ignored. Thus, the local *DomainParticipant* would have to call `ignore_participant()` again to re-ignore the replaced entity.

**Note:** In this release, ignored publications and subscriptions are never replaced in the ‘ignore’ table. Since this table also contains the ignored *DomainParticipants*, a call to `ignore_participant()` will fail if `ignored_entity_allocation.max_count` is reached and none of the ignored entities is a *DomainParticipant*.

## 27.5 Supervising Endpoint Discovery

It is possible to control for which *DomainParticipants* endpoint discovery may occur. You can configure this behavior with the `enable_endpoint_discovery` field in the [44.2 DISCOVERY QoS Policy \(DDS Extension\) on page 699](#):

- When set to `TRUE` (the default value), endpoint discovery will automatically occur for every discovered *DomainParticipant*. This is the normal operation of the discovery process.
- When set to `FALSE`, endpoint discovery will be disabled for every discovered *DomainParticipant*. Then applications will have to manually enable endpoint discovery (described below)

for the *DomainParticipants* they are interested in communicating with. By disabling endpoint discovery, the *DomainParticipant* will not store any state about remote endpoints and will not send local endpoint information to remote *DomainParticipants*.

When **enable\_endpoint\_discovery** is set to FALSE, you have two options after a remote *DomainParticipant* is discovered:

- Call the *DomainParticipant*'s **resume\_endpoint\_discovery()** operation to enable endpoint discovery. After invoking this operation, the *DomainParticipant* will start to exchange endpoint information so that matching and communication can occur with the remote *DomainParticipant*.

```
DDS_ReturnCode_t resume_endpoint_discovery(
    const DDS_InstanceHandle_t & remote_participant_handle)
```

Or

- Call the *DomainParticipant*'s **ignore\_participant()** operation to permanently ignore endpoint discovery with the remote *DomainParticipant*.

Setting **enable\_endpoint\_discovery** to FALSE enables application-level authentication use cases, in which a *DomainParticipant* will resume endpoint discovery with a remote *DomainParticipant* after successful authentication at the application level. The following example shows how to provide access control using this feature:

```
class MyParticipantBuiltinTopicDataListener :
    public DDSDataReaderListener {
public:
    virtual void on_data_available(DDSDataReader *reader);
    // ...
};

void MyParticipantBuiltinTopicDataListener::on_data_available(
    DDSDataReader *reader) {
    DDSParticipantBuiltinTopicDataDataReader
    *builtinTopicDataReader =
        DDSParticipantBuiltinTopicDataDataReader *) reader;
    DDS_ParticipantBuiltinTopicDataSeq data_seq;
    DDS_SampleInfoSeq info_seq;
    int = 0;
    if (builtinTopicDataReader->take(
        data_seq, info_seq,
        DDS_LENGTH_UNLIMITED,
        DDS_ANY_SAMPLE_STATE,
        DDS_ANY_VIEW_STATE,
        DDS_ANY_INSTANCE_STATE) != DDS_RETCODE_OK) {
        // ... error
    }
    for (i = 0; i < data_seq.length(); ++i) {
        if (info_seq[i].valid_data) {
            DDSDomainParticipant * localParticipant =
                builtinTopicDataReader->
```

```
get_subscriber()->get_participant();
DDS_ReturnCode_t retCode;
// check user_data for access control
if (data_seq[i].user_data[0] != 0x9) {
    retCode = localParticipant->
        ignore_participant(
            info_seq[i].instance_handle);
} else {
    retCode = localParticipant->
        resume_endpoint_discovery(
            info_seq[i].instance_handle)
}
}
}
if (builtinTopicDataReader->return_loan(
    data_seq, info_seq)
    != DDS_RETCODE_OK) {
    // ... error }
}
```

# Chapter 28 Accessing Discovery Information through Built-In Topics

This chapter discusses how to use Built-in Topics.

*Connex* must discover and keep track of remote entities, such as new participants in the DDS domain. This information may also be important to the application itself, which may want to react to this discovery or access it on demand. To support these needs, *Connex* provides *built-in Topics* (“DCPSParticipant”, “DCPSPublication”, “DCPSSubscription” in [Figure 25.1: Built-in Writers and Readers for Discovery on page 332](#)) and the corresponding built-in *DataReaders* that you can use to access this discovery information.

The discovery information is accessed just as if it is normal application data. This allows the application to know (either via listeners or by polling) when there are any changes in those values. Note that only entities that belong to a *different DomainParticipant* are being discovered and can be accessed through the built-in readers. Entities that are created within the local *DomainParticipant* are not included as part of the data that can be accessed by the built-in readers.

Built-in topics contain information about the remote entities, including their QoS policies. These QoS policies appear as normal fields inside the topic’s data, which can be read by means of the built-in Topic. Additional information is provided to identify the entity and facilitate the application logic.

## 28.1 Listeners for Built-in Entities

Built-in entities have default listener settings:

- The built-in *Subscriber* and its built-in topics have 'nil' listeners—all status bits are set in the listener masks, but the listener is NULL. This effectively creates a NO-OP listener

that does not reset communication status.

- Built-in *DataReaders* have null listeners with no status bits set in their masks.

This approach prevents callbacks to the built-in *DataReader* listeners from invoking your *DomainParticipant*'s listeners, and at the same time ensures that the status changed flag is not reset. For more information, see [Table 15.3 Effect of Different Combinations of Listeners and Status Bit Masks](#) and [15.8.5 Hierarchical Processing of Listeners on page 51](#).

## 28.2 Built-in DataReaders

Built-in *DataReaders* belong to a built-in *Subscriber*, which can be retrieved by using the *DomainParticipant*'s `get_builtin_subscriber()` operation. You can retrieve the built-in *DataReaders* by using the *Subscriber*'s `lookup_datareader()` operation, which takes the Topic name as a parameter. The built-in *DataReader* is created when `lookup_datareader()` is called on a built-in topic for the first time.

To conserve memory, built-in *Subscribers* and *DataReaders* are created only if and when you look them up. Therefore, if you do not want to miss any built-in data, you should look up the built-in readers before the *DomainParticipant* is enabled.

The following tables describe the built-in topics and their data types. The [47.30 USER\\_DATA QosPolicy on page 864](#), [45.1 TOPIC\\_DATA QosPolicy on page 737](#) and [46.4 GROUP\\_DATA QosPolicy on page 748](#) are included as part of the built-in data type and are not used by *Connex*. Therefore, you can use them to send application-specific information.

Built-in topics can be used in conjunction with the `ignore_*()` operations to ignore certain entities (see [Chapter 27 Restricting Communication—Ignoring Entities on page 352](#)).

**Table 28.1 Participant Built-in Topic's Data Type (DDS\_ParticipantBuiltinTopicData)**

Type	Field	Description
DDS_BuiltinTopicKey	key	Key to distinguish the discovered <i>DomainParticipant</i>
DDS_User-DataQosPolicy	user_data	Data that can be set when the related <i>DomainParticipant</i> is created (via the <a href="#">47.30 USER_DATA QosPolicy on page 864</a> ) and that the application may use as it wishes (e.g., to perform some security checking).
DDS_PropertyQosPolicy	property	Pairs of names/values to be stored with the <i>DomainParticipant</i> . See <a href="#">47.19 PROPERTY QosPolicy (DDS Extension) on page 837</a> . The usage is strictly application-dependent.
DDS_ProtocolVersion_t	rtps_protocol_version	Version number of the RTPS wire protocol used.
DDS_VendorId_t	rtps_vendor_id	ID of vendor implementing the RTPS wire protocol.
DDS_UnsignedLong	dds_builtin_endpoints	Bitmap set by the discovery plugins. Each bit in this field indicates a built-in endpoint present for discovery.

Table 28.1 Participant Built-in Topic's Data Type (DDS\_ParticipantBuiltinTopicData)

Type	Field	Description
DDS_LocatorSeq	default_uni- cast_ locators	If the TransportUnicastQosPolicy is not specified when a <i>DataWriter/DataReader</i> is created, the unicast_locators in the corresponding Publication/Subscription built-in topic data will be empty. When the unicast_locators in the Publication/SubscriptionBuiltinTopicData is empty, the default_uni- cast_locators in the corresponding Participant Builtin Topic Data is assumed.  If default_uni- cast_locators is empty, it defaults to DomainParticipantQos.default_uni- cast.
DDS_ProductVersion_t	product_ version	Vendor-specific parameter. The current version of <i>Connex</i> .
DDS_ EntityNameQosPolicy	participant_ name	Name and role_name assigned to the <i>DomainParticipant</i> . See <a href="#">47.11 ENTITY_NAME QosPolicy (DDS Extension) on page 817</a> .
DDS_DomainId_t	domain_id	Domain ID associated with the discovered participant.
DDS_TransportInfoSeq	transport_ info	A sequence of DDS_TransportInfo_t containing information about each of the installed transports of the discovered <i>DomainParticipant</i> .  A DDS_TransportInfo_t structure contains the class_id and message_size_max for a single transport.  The maximum length of this sequence is controlled by the <a href="#">44.4 DOMAIN_PARTICIPANT_RESOURCE_LIMITS QosPolicy (DDS Extension) on page 714</a> transport_info_list_max_length (see <a href="#">Table 44.5 DDS_DomainParticipantResourceLimitsQosPolicy</a> ).  <i>Connex</i> uses the transport information propagated via discovery to detect potential misconfigurations in a <i>Connex</i> distributed system. If two <i>DomainParticipants</i> that discover each other have one common transport with different values for message_size_max, <i>Connex</i> prints a warning message about that condition.
DDS_ServiceQosPolicy	service	Service associated with the discovered <i>DomainParticipant</i> .

Table 28.2 Publication Built-in Topic's Data Type (DDS\_PublicationBuiltinTopicData)

Type	Field	Description
DDS_BuiltinTopicKey_t	key	Key to distinguish the discovered <i>DataWriter</i>
DDS_BuiltinTopicKey_t	participant_key	Key to distinguish the participant to which the discovered <i>DataWriter</i> belongs
DDS_String	topic_name	Topic name of the discovered <i>DataWriter</i>
DDS_String	type_name	Type name attached to the topic of the discovered <i>DataWriter</i>

Table 28.2 Publication Built-in Topic's Data Type (DDS\_PublicationBuiltinTopicData)

Type	Field	Description
DDS_DurabilityQosPolicy	durability	QosPolicies of the discovered <i>DataWriter</i>
DDS_DurabilityService-QosPolicy	durability_service	
DDS_DeadlineQosPolicy	deadline	
DDS_DestinationOrder-QosPolicy	destination_order	
DDS_LatencyBudget-QosPolicy	latency_budget	
DDS_LivelinessQosPolicy	liveliness	
DDS_ReliabilityQosPolicy	reliability	
DDS_LifespanQosPolicy	lifespan	
DDS_UserDataQosPolicy	user_data	Data that can be set when the <i>DataWriter</i> is created (via the <a href="#">47.30 USER_DATA QosPolicy on page 864</a> ) and that the application may use as it wishes.
DDS_OwnershipQosPolicy	ownership	QosPolicies of the discovered <i>DataWriter</i>
DDS_OwnershipStrength-QosPolicy	ownership_strength	
DDS_DestinationOrder-QosPolicy	destination_order	
DDS_PresentationQosPolicy	presentation	
DDS_PartitionQosPolicy	partition	Name of the partition, set in the <a href="#">46.5 PARTITION QosPolicy on page 751</a> for the publisher to which the discovered <i>DataWriter</i> belongs
DDS_TopicDataQosPolicy	topic_data	Data that can be set when the <i>Topic</i> (with which the discovered <i>DataWriter</i> is associated) is created (via the <a href="#">45.1 TOPIC_DATA QosPolicy on page 737</a> ) and that the application may use as it wishes.
DDS_GroupDataQosPolicy	group_data	Data that can be set when the <i>Publisher</i> to which the discovered <i>DataWriter</i> belongs is created (via the <a href="#">46.4 GROUP_DATA QosPolicy on page 748</a> ) and that the application may use as it wishes.
DDS_TypeObject *	type	Describes the type of the remote <i>DataReader</i> . See the API Reference HTML documentation.
DDS_DataRepresentationQosPolicy	representation	Data representations that the <i>DataWriter</i> offers. See <a href="#">47.3 DATA_REPRESENTATION QosPolicy on page 780</a> .
DDS_DataTagQosPolicy	data_tags	Data tags (pairs of names/values) assigned to the corresponding <i>DataWriter</i> . Usage is strictly application-dependent. See <a href="#">47.4 DATATAG QosPolicy on page 787</a> .
DDS_TypeCode *	type_code	Type code information about this <i>Topic</i> . See <a href="#">17.7 Using Generated Types without Connex (Standalone) on page 234</a> .
DDS_BuiltinTopicKey_t	publisher_key	The key of the <i>Publisher</i> to which the <i>DataWriter</i> belongs.

Table 28.2 Publication Built-in Topic's Data Type (DDS\_PublicationBuiltinTopicData)

Type	Field	Description
DDS_PropertyQosPolicy	property	Properties (pairs of names/values) assigned to the corresponding <i>DataWriter</i> . Usage is strictly application-dependent. See <a href="#">47.19 PROPERTY QoS Policy (DDS Extension) on page 837</a> .
DDS_LocatorSeq	unicast_locators	If the TransportUnicastQoSPolicy is not specified when a <i>DataWriter/DataReader</i> is created, the unicast_locators in the corresponding Publication/Subscription built-in topic data will be empty. When the unicast_locators in the Publication/SubscriptionBuiltinTopicData is empty, the default_unicast_locators in the corresponding Participant Builtin Topic Data is assumed.
DDS_GUID_t	virtual_guid	Virtual GUID for the corresponding <i>DataWriter</i> . For more information, see <a href="#">21.2 Durability and Persistence Based on Virtual GUIDs on page 293</a> .
DDS_ServiceQosPolicy	service	Service associated with the discovered <i>DataWriter</i> .
DDS_ProtocolVersion_t	rtps_protocol_version	Version number of the RTPS wire protocol in use.
DDS_VendorId_t	rtps_vendor_id	ID of the vendor implementing the RTPS wire protocol.
DDS_Product_Version_t	product_version	Vendor-specific value. For RTI, this is the current version of <i>Connex</i> .
DDS_LocatorFilterQosPolicy	locator_filter	When the <a href="#">47.16 MULTI_CHANNEL QoS Policy (DDS Extension) on page 830</a> is used on the discovered <i>DataWriter</i> , the locator_filter contains the sequence of LocatorFilters in that policy. There is one LocatorFilter per <i>DataWriter</i> channel. A channel is defined by a filter expression and a sequence of multicast locators. See <a href="#">28.2.1 LOCATOR_FILTER QoS Policy (DDS Extension) on page 367</a> .
DDS_Boolean	disable_positive_acks	Vendor specific parameter. Determines whether matching <i>DataReaders</i> send positive acknowledgements for reliability.
DDS_EntityNameQosPolicy	publication_name	Name and role_name assigned to the <i>DataWriter</i> . See <a href="#">47.11 ENTITY_NAME QoS Policy (DDS Extension) on page 817</a> .

Table 28.3 Subscription Built-in Topic's Data Type (DDS\_SubscriptionBuiltinTopicData)

Type	Field	Description
DDS_BuiltinTopicKey_t	key	Key to distinguish the discovered <i>DataReader</i> .
DDS_BuiltinTopicKey_t	participant_key	Key to distinguish the participant to which the discovered <i>DataReader</i> belongs.
char *	topic_name	Topic name of the discovered <i>DataReader</i> .
char *	type_name	Type name attached to the <i>Topic</i> of the discovered <i>DataReader</i> .

Table 28.3 Subscription Built-in Topic's Data Type (DDS\_SubscriptionBuiltinTopicData)

Type	Field	Description
DDS_DurabilityQosPolicy	durability	QosPolicies of the discovered <i>DataReader</i>
DDS_DeadlineQosPolicy	deadline	
DDS_LatencyBudget-QosPolicy	latency_budget	
DDS_LivelinessQosPolicy	liveliness	
DDS_ReliabilityQosPolicy	reliability	
DDS_OwnershipQosPolicy	ownership	
DDS_DestinationOrderQosPolicy	destination_order	
DDS_UserDataQosPolicy	user_data	Data that can be set when the <i>DataReader</i> is created (via the <a href="#">47.30 USER_DATA QosPolicy on page 864</a> ) and that the application may use as it wishes.
DDS_TimeBasedFilterQosPolicy	time_based_filter	QosPolicies of the discovered <i>DataReader</i>
DDS_PresentationQosPolicy	presentation	
DDS_PartitionQosPolicy	partition	Name of the partition, set in the <a href="#">46.5 PARTITION QosPolicy on page 751</a> for the <i>Subscriber</i> to which the discovered <i>DataReader</i> belongs.
DDS_TopicDataQosPolicy	topic_data	Data that can be set when the <i>Topic</i> to which the discovered <i>DataReader</i> belongs is created (via the <a href="#">45.1 TOPIC_DATA QosPolicy on page 737</a> ) and that the application may use as it wishes.
DDS_GroupDataQosPolicy	group_data	Data that can be set when the <i>Publisher</i> to which the discovered <i>DataReader</i> belongs is created (via the <a href="#">46.4 GROUP_DATA QosPolicy on page 748</a> ) and that the application may use as it wishes.
DDS_TypeObject *	type	Describes the type of the remote <i>DataReader</i> . See the API Reference HTML documentation.
DDS_TypeConsistencyEnforcementQosPolicy	type_consistency	Indicates the type-consistency requirements of the remote <i>DataReader</i> . See <a href="#">48.6 TYPE_CONSISTENCY_ENFORCEMENT QosPolicy on page 894</a> and the <a href="#">RTI Connext Core Libraries Extensible Types Guide</a> .
DDS_DataRepresentationQosPolicy	representation	Data representations that the <i>DataReader</i> requests. See <a href="#">47.3 DATA_REPRESENTATION QosPolicy on page 780</a> .
DDS_DataTagQosPolicy	data_tags	Data tags (pairs of names/values) assigned to the corresponding <i>DataReader</i> . Usage is strictly application-dependent. See <a href="#">47.4 DATATAG QosPolicy on page 787</a> .
DDS_TypeCode *	type_code	Type code information about this <i>Topic</i> . See <a href="#">17.7 Using Generated Types without Connext (Standalone) on page 234</a> .
DDS_BuiltinTopicKey_t	subscriber_key	Key of the <i>Subscriber</i> to which the <i>DataReader</i> belongs.
DDS_PropertyQosPolicy	property	Properties (pairs of names/values) assigned to the corresponding <i>DataReader</i> . Usage is strictly application-dependent. See <a href="#">47.19 PROPERTY QosPolicy (DDS Extension) on page 837</a> .

Table 28.3 Subscription Built-in Topic's Data Type (DDS\_SubscriptionBuiltinTopicData)

Type	Field	Description
DDS_LocatorSeq	unicast_locators	If the TransportUnicastQosPolicy is not specified when a <i>DataWriter/DataReader</i> is created, the unicast_locators in the corresponding Publication/Subscription builtin topic data will be empty. When the unicast_locators in the Publication/SubscriptionBuiltinTopicData is empty, the default_unicast_locators in the corresponding Participant Builtin Topic Data is assumed.
DDS_LocatorSeq	multicast_locators	Custom multicast locators that the endpoint can specify.
DDS_ContentFilter-Property_t	content_filter_property	Provides all the required information to enable content filtering on the writer side.
DDS_GUID_t	virtual_guid	Virtual GUID for the corresponding <i>DataReader</i> . For more information, see <a href="#">21.2 Durability and Persistence Based on Virtual GUIDs on page 293</a> .
DDS_ServiceQosPolicy	service	Service associated with the discovered <i>DataReader</i> .
DDS_ProtocolVersion_t	rtps_protocol_version	Version number of the RTPS wire protocol in use.
DDS_VendorId_t	rtps_vendor_id	ID of the vendor implementing the RTPS wire protocol.
DDS_Product_Version_t	product_version	Vendor-specific value. For RT1, this is the current version of <i>Connex</i> .
DDS_Boolean	disable_positive_acks	Vendor specific parameter. Determines whether matching <i>DataReaders</i> send positive acknowledgements for reliability.
DDS_EntityNameQosPolicy	subscription_name	Name and role_name assigned to the <i>DataReader</i> . See <a href="#">47.11 ENTITY_NAME QosPolicy (DDS Extension) on page 817</a> .

Table 28.4 Topic Built-in Topic's Data Type (DDS\_TopicBuiltinTopicData)

Type	Field	Description
DDS_BuiltinTopicKey_t	key	Key to distinguish the discovered <i>Topic</i>
DDS_String	name	<i>Topic</i> name
DDS_String	type_name	type name attached to the <i>Topic</i>

**Table 28.4 Topic Built-in Topic's Data Type (DDS\_TopicBuiltinTopicData)**

Type	Field	Description
DDS_DurabilityQosPolicy	durability	QosPolicy of the discovered <i>Topic</i>
DDS_DurabilityServiceQosPolicy	durability_service	
DDS_DeadlineQosPolicy	deadline	
DDS_LatencyBudgetQosPolicy	latency_budget	
DDS_LivelinessQosPolicy	liveliness	
DDS_ReliabilityQosPolicy	reliability	
DDS_TransportPriorityQosPolicy	transport_priority	
DDS_LifespanQosPolicy	lifespan	
DDS_DestinationOrderQosPolicy	destination_order	
DDS_HistoryQosPolicy	history	
DDS_ResourceLimitsQosPolicy	resource_limits	
DDS_OwnershipQosPolicy	ownership	Data that can be set when the <i>Topic</i> to which the discovered <i>DataReader</i> belongs is created (via the <a href="#">45.1 TOPIC_DATA QosPolicy on page 737</a> ) and that the application may use as it wishes.
DDS_TopicDataQosPolicy	topic_data	

[Table 28.5 QoS of Built-in Subscriber and DataReader](#) lists the QoS of the built-in *Subscriber* and *DataReader* created for accessing discovery data. These are provided for your reference only; they cannot be changed.

**Table 28.5 QoS of Built-in Subscriber and DataReader**

QosPolicy	Value
Deadline	period = infinite
DestinationOrder	kind = BY_RECEPTION_TIMESTAMP_DESTINATIONORDER_QOS
Durability	kind = TRANSIENT_LOCAL_DURABILITY_QOS
EntityFactory	autoenable_created_entities = TRUE
GroupData	value = empty sequence
History	kind = KEEP_LAST_HISTORY_QOS depth = 1

Table 28.5 QoS of Built-in Subscriber and DataReader

QoSPolicy	Value
LatencyBudget	duration = 0
Liveliness	kind = AUTOMATIC_LIVELINESS_QOS lease_duration = infinite
Ownership	kind = SHARED_OWNERSHIP_QOS
Ownership Strength	value = 0
Presentation	access_scope = TOPIC_PRESENTATION_QOS coherent_access = FALSE ordered_access = FALSE
Partition	name = empty sequence
ReaderDataLifecycle	autopurge_nowriter_samples_delay = infinite
Reliability	kind = RELIABLE_RELIABILITY_QOS max_blocking_time is irrelevant for the <i>DataReader</i>
ResourceLimits	Depends on setting of DomainParticipantResourceLimitsQoSPolicy and DiscoveryConfigQoSPolicy in DomainParticipantQoS: max_samples = domainParticipantQos.discovery_config. [participant/publication/subscription]_reader_resource_limits.max_samples max_instances = domainParticipantQos.resource_limits. [remote_writer/reader/participant]_allocation.max_count max_samples_per_instance = 1
TimeBasedFilter	minimum_separation = 0
TopicData	value = empty sequence
UserData	value = empty sequence

**Note:**

The DDS\_TopicBuiltinTopicData built-in topic (described in [Table 28.4 Topic Built-in Topic's Data Type \(DDS\\_TopicBuiltinTopicData\)](#)) is meant to convey information about discovered *Topics*. However, this topic's data is not sent separately and therefore a *DataReader* for DDS\_TopicBuiltinTopicData will not receive any data. Instead, DDS\_TopicBuiltinTopicData data is included in the information carried by the built-in topics for Publications and Subscriptions (DDS\_PublicationBuiltinTopicData and DDS\_SubscriptionBuiltinTopicData) and can be accessed with their built-in *DataReaders*.

**28.2.1 LOCATOR\_FILTER QoS Policy (DDS Extension)**

The LocatorFilter QoS Policy is only applicable to the built-in topic for a Publication (see [Table 28.2 Publication Built-in Topic's Data Type \(DDS\\_PublicationBuiltinTopicData\)](#)).

Table 28.6 DDS\_LocatorFilterQosPolicy

Type	Field Name	Description
DDS_LocatorFilterSeq	locator_filters	A sequence of locator filters, described in <a href="#">Table 28.7 DDS_LocatorFilter_t</a> . There is one locator filter per <i>DataWriter</i> channel. If the length of the sequence is zero, the <i>DataWriter</i> is not using multi-channel.
char *	filter_name	Name of the filter class used to describe the locator filter expressions. The following two values are supported: <ul style="list-style-type: none"> <li>DDS_SQLFILTER_NAME</li> <li>DDS_STRINGMATCHFILTER_NAME</li> </ul>

Table 28.7 DDS\_LocatorFilter\_t

Type	Field Name	Description
DDS_LocatorSeq	locators	A sequence of multicast address locators for the locator filter. See <a href="#">Table 28.8 DDS_Locator_t</a> .
char *	filter_expression	A logical expression used to determine if the data will be published in the channel associated with this locator filter. See <a href="#">35.5 SQL Filter Expression Notation on page 555</a> and <a href="#">35.6 STRINGMATCH Filter Expression Notation on page 564</a> for information about the expression syntax.

Table 28.8 DDS\_Locator\_t

Type	Field Name	Description
DDS_Long	kind	If the locator kind is DDS_LOCATOR_KIND_UDPv4, the address contains an IPv4 address. The leading 12 octets of the address must be zero. The last 4 octets store the IPv4 address. If the locator kind is DDS_LOCATOR_KIND_UDPv6, the address contains an IPv6 address. IPv6 addresses typically use a shorthand hexadecimal notation that maps one-to-one to the 16 octets of the address. In C#, the locator kinds for UDPv4 and UDPv6 addresses are Locator_t.LOCATOR_KIND_UDPv4 and Locator_t.LOCATOR_KIND_UDPv6.
DDS_Octet [16]	address	The locator address.
DDS_UnsignedLong	port	The locator port number.

## 28.3 Accessing the Built-in Subscriber

Getting the built-in subscriber allows you to retrieve the built-in readers of the built-in topics through the *Subscriber's* `lookup_datareader()` operation. By accessing the built-in reader, you can access discovery information about remote entities.

```
// Lookup built-in reader
DDSDataReader *builtin_reader =
builtin_subscriber->lookup_datareader(DDS_PUBLICATION_TOPIC_NAME);

if (builtin_reader == NULL) {
    // ... error
}
// Register listener to built-in reader
MyPublicationBuiltinTopicDataListener builtin_reader_listener =
new MyPublicationBuiltinTopicDataListener();

if (builtin_reader->set_listener(builtin_reader_listener,
DDS_DATA_AVAILABLE_STATUS) != DDS_RETCODE_OK) {
    // ... error
}
// enable DomainParticipant
if (participant->enable() != DDS_RETCODE_OK) {
    // ... error
}
```

For example, you can call the *DomainParticipant*'s `get_builtin_subscriber()` operation, which will provide you with a built-in Subscriber. Then you can use that built-in Subscriber to call the *Subscriber*'s `lookup_datareader()` operation; this will retrieve the built-in reader. Another option is to register a *Listener* on the built-in subscriber instead, or poll for the status of the built-in subscriber to see if any of the built-in data readers have received data.

# Part 5: Sending Data with Connex

The following sections discuss how to create, configure, and use *Publishers* and *DataWriters* to send data. They describe how these *Entities* interact, as well as the types of operations that are available for them:

- [Overview of Sending Data \(Chapter 29 on page 371\)](#)
- [Publishers \(Chapter 30 on page 373\)](#)
- [DataWriters \(Chapter 31 on page 389\)](#)

The goal of these sections is to help you become familiar with the *Entities* you need for sending data. For up-to-date details such as formal parameters and return codes on any mentioned operations, please see the API Reference HTML documentation.

The following sections describe other topics related to sending data:

- [Reliability Models for Sending Data \(Chapter 32 on page 446\)](#)
- [Guaranteed Delivery of Data \(Chapter 33 on page 485\)](#)
- [Sending Large Data \(Chapter 34 on page 497\)](#)
- [Filtering Data \(Chapter 35 on page 546\)](#)
- [Multi-Channel DataWriters for High-Performance Filtering \(Chapter 36 on page 576\)](#)
- [Collaborative DataWriters \(Maintain Global, Ordered Set of Samples\) \(Chapter 37 on page 588\)](#)

# Chapter 29 Overview of Sending Data

To send DDS samples of a data instance:

1. Create and configure the required *Entities*:
  - a. Create a *DomainParticipant* (see [16.3.1 Creating a DomainParticipant on page 87](#)).
  - b. Register user data types<sup>1</sup> with the *DomainParticipant*. For example, the **'FooDataType'**. (This step is not necessary in the Modern C++ API--the Topic instantiation automatically registers the type)
  - c. Use the *DomainParticipant* to create a *Topic* with the registered data type.
  - d. Optionally<sup>2</sup>, use the *DomainParticipant* to create a *Publisher*.
  - e. Use the *Publisher* or *DomainParticipant* to create a *DataWriter* for the *Topic*.
  - f. Use a type-safe method to cast the generic *DataWriter* created by the *Publisher* to a type-specific *DataWriter*. For example, **'FooDataWriter'**. (This step doesn't apply to the Modern C++ API where you directly instantiate a type-safe **'DataWriter-<Foo>.'**)
  - g. Optionally, register data instances with the *DataWriter*. If the *Topic*'s user data type contain *key* fields, then registering a data *instance* (data with a specific key value) will improve performance when repeatedly sending data with the same key. You may register many different data instances; each registration will return an *instance handle* corresponding to the specific key value. For non-keyed data types, instance registration has no effect. See [Chapter 8 DDS Samples, Instances, and Keys on page 17](#) for more information on keyed data types and instances.

---

<sup>1</sup>Type registration is not required for built-in types (see [17.2.1 Registering Built-in Types on page 122](#)).

<sup>2</sup>You are not required to explicitly create a *Publisher*; instead, you can use the 'implicit *Publisher*' created from the *DomainParticipant*. See [30.1 Creating Publishers Explicitly vs. Implicitly on page 376](#).

2. Every time there is changed data to be published:
  - a. Store the data in a variable of the correct data type (for instance, variable **'Foo'** of the type **'FooDataType'**).
  - b. Call the **FooDataWriter's write()** operation, passing it a reference to the variable **'Foo'**.
    - For non-keyed data types or for non-registered instances, also pass in **DDS\_HANDLE\_NIL**.
    - For keyed data types, pass in the instance handle corresponding to the instance stored in **'Foo'**, if you have registered the instance previously. This means that the data stored in **'Foo'** has the same key value that was used to create instance handle.
  - c. The **write()** function will take a snapshot of the contents of **'Foo'** and store it in *Connex* internal buffers from where the DDS data sample is sent under the criteria set by the *Publisher's* and *DataWriter's* QoS Policies. If there are matched *DataReaders*, then the DDS data sample will have been passed to the physical transport plug-in/device driver by the time that **write()** returns.

# Chapter 30 Publishers

An application that intends to publish information needs the following *Entities*: *DomainParticipant*, *Topic*, *Publisher*, and *DataWriter*. All *Entities* have a corresponding specialized *Listener* and a set of *QosPolicies*. A *Listener* is how *Connex* notifies your application of status changes relevant to the *Entity*. The *QosPolicies* allow your application to configure the behavior and resources of the *Entity*.

- A *DomainParticipant* defines the DDS domain in which the information will be made available.
- A *Topic* defines the name under which the data will be published, as well as the type (format) of the data itself.
- An application writes data using a *DataWriter*. The *DataWriter* is bound at creation time to a *Topic*, thus specifying the name under which the *DataWriter* will publish the data and the type associated with the data. The application uses the *DataWriter*'s **write()** operation to indicate that a new value of the data is available for dissemination.
- A *Publisher* manages the activities of several *DataWriters*. The *Publisher* determines when the data is actually sent to other applications. Depending on the settings of various *QosPolicies* of the *Publisher* and *DataWriter*, data may be buffered to be sent with the data of other *DataWriters* or not sent at all. By default, the data is sent as soon as the *DataWriter*'s **write()** function is called.

You may have multiple *Publishers*, each managing a different set of *DataWriters*, or you may choose to use one *Publisher* for all your *DataWriters*.

For more information, see [30.1 Creating Publishers Explicitly vs. Implicitly on page 376](#).

[Figure 30.1: Publication Module on the next page](#) shows how these *Entities* are related, as well as the methods defined for each *Entity*.

Table 30.1 Publisher Operations

Working with ...	Operation	Description	Reference
DataWriters	begin_coherent_changes	Indicates that the application will begin a coherent set of modifications.	<a href="#">31.10 Writing Coherent Sets of DDS Data Samples on page 417</a>
	create_datawriter	Creates a <i>DataWriter</i> that will belong to the <i>Publisher</i> .	<a href="#">31.1 Creating DataWriters on page 393</a>
	create_datawriter_with_profile	Sets the <i>DataWriter's</i> QoS based on a specified QoS profile.	
	copy_from_topic_qos	Copies relevant QoS Policies from a <i>Topic</i> into a <i>DataWriterQoS</i> structure.	<a href="#">30.4.6 Other Publisher QoS-Related Operations on page 384</a>
DataWriters cont'd	delete_contained_entities	Deletes all of the <i>DataWriters</i> that were created by the <i>Publisher</i> .	<a href="#">30.3.1 Deleting Contained DataWriters on page 379</a>
	delete_datawriter	<i>Deletes a DataWriter</i> that belongs to the <i>Publisher</i> .	<a href="#">31.3 Deleting DataWriters on page 395</a>
	end_coherent_changes	Ends the coherent set initiated by <code>begin_coherent_changes()</code> .	<a href="#">31.10 Writing Coherent Sets of DDS Data Samples on page 417</a>
DataWriters cont'd	get_all_datawriters	Retrieves all the <i>DataWriters</i> created from this <i>Publisher</i> .	<a href="#">31.2 Getting All DataWriters on page 395</a>
	get_default_datawriter_qos	Copies the <i>Publisher's</i> default <i>DataWriterQoS</i> values into a <i>DataWriterQoS</i> structure.	<a href="#">31.15 Setting DataWriter QoS Policies on page 433</a>
	get_status_changes	Will always return 0 since there are no Statuses currently defined for <i>Publishers</i> .	<a href="#">15.4 Getting Status and Status Changes on page 38</a>
	lookup_datawriter	Retrieves a <i>DataWriter</i> previously created for a specific <i>Topic</i> .	<a href="#">30.6 Finding a Publisher's Related DDS Entities on page 387</a>
DataWriters cont'd	set_default_datawriter_qos	Sets or changes the default <i>DataWriterQoS</i> values.	<a href="#">30.4.5 Getting and Setting Default QoS for DataWriters on page 383</a>
	set_default_datawriter_qos_with_profile	Sets or changes the default <i>DataWriterQoS</i> values based on a QoS profile.	
	wait_for_acknowledgments	Blocks until all data written by the <i>Publisher's</i> reliable <i>DataWriters</i> are acknowledged by all matched reliable <i>DataReaders</i> , or until the a specified timeout duration, <code>max_wait</code> , elapses.	<a href="#">30.7 Waiting for Acknowledgments in a Publisher on page 387</a>
	is_sample_app_acked	Indicates if a sample has been application-acknowledged by all the matching <i>DataReaders</i> that were alive when the sample was written.  If a <i>DataReader</i> does not enable application acknowledgment (by setting the <i>ReliabilityQoSPolicy's</i> <code>acknowledgment_kind</code> to a value other than <code>DDS_PROTOCOL_ACKNOWLEDGMENT_MODE</code> ), the sample is considered application-acknowledged for that <i>DataReader</i> .	<a href="#">31.12 Application Acknowledgment on page 418</a>

Table 30.1 Publisher Operations

Working with ...	Operation	Description	Reference
Libraries and Profiles	get_default_library	Gets the <i>Publisher's</i> default QoS profile library.	<a href="#">30.4.4 Getting and Setting the Publisher's Default QoS Profile and Library on page 383</a>
	get_default_profile	Gets the <i>Publisher's</i> default QoS profile.	
	get_default_profile_library	Gets the library that contains the <i>Publisher's</i> default QoS profile.	
	set_default_library	Sets the default library for a <i>Publisher</i> .	
	set_default_profile	Sets the default profile for a <i>Publisher</i> .	
Participants	get_participant	Gets the <i>DomainParticipant</i> that was used to create the <i>Publisher</i> .	<a href="#">30.6 Finding a Publisher's Related DDS Entities on page 387</a>
Publishers	enable	Enables the <i>Publisher</i> .	<a href="#">15.2 Enabling DDS Entities on page 35</a>
	equals	Compares two <i>Publisher's</i> QoS structures for equality.	<a href="#">30.4.2 Comparing QoS Values on page 382</a>
	get_qos	Gets the <i>Publisher's</i> current QoSPolicy settings. This is most often used in preparation for calling set_qos().	<a href="#">30.4 Setting Publisher QoS Policies on page 379</a>
	set_qos	Sets the <i>Publisher's</i> QoS. You can use this operation to change the values for the <i>Publisher's</i> QoS Policies. Note, however, that not all QoS Policies can be changed after the <i>Publisher</i> has been created.	
	set_qos_with_profile	Sets the <i>Publisher's</i> QoS based on a specified QoS profile.	
Publishers cont'd	get_listener	Gets the currently installed Listener.	<a href="#">30.5 Setting Up PublisherListeners on page 385</a>
	set_listener	Sets the <i>Publisher's</i> Listener. If you created the <i>Publisher</i> without a Listener, you can use this operation to add one later.	
	suspend_publications	Provides a <i>hint</i> that multiple data-objects within the <i>Publisher</i> are about to be written. <i>Connext</i> does not currently use this hint.	<a href="#">30.9 Suspending and Resuming Publications on page 388</a>
	resume_publications	Reverses the action of suspend_publications().	

## 30.1 Creating Publishers Explicitly vs. Implicitly

To send data, your application must have a *Publisher*. However, you are not required to explicitly create one. If you do not create one, the middleware will implicitly create a *Publisher* the first time you create a *DataWriter* using the *DomainParticipant's* operations. It will be created with default QoS (DDS\_PUBLISHER\_QOS\_DEFAULT) and no Listener.

A *Publisher* (implicit or explicit) gets its own default QoS and the default QoS for its child *DataWriters* from the *DomainParticipant*. These default QoS are set when the *Publisher* is created. (This is true for *Subscribers* and *DataReaders*, too.)

The 'implicit *Publisher*' can be accessed using the *DomainParticipant*'s `get_implicit_publisher()` operation (see [16.3.10 Getting the Implicit Publisher or Subscriber on page 103](#)). You can use this 'implicit *Publisher*' just like any other *Publisher* (it has the same operations, QoS Policies, etc.). So you can change the mutable QoS and set a Listener if desired.

*DataWriters* are created by calling `create_datawriter()` or `create_datawriter_with_profile()`—these operations exist for *DomainParticipants* and *Publishers*. If you use the *DomainParticipant* to create a *DataWriter*, it will belong to the implicit *Publisher*. If you use a *Publisher* to create a *DataWriter*, it will belong to that *Publisher*.

The middleware will use the same implicit *Publisher* for all *DataWriters* that are created using the *DomainParticipant*'s operations.

Having the middleware implicitly create a *Publisher* allows you to skip the step of creating a *Publisher*. However, having all your *DataWriters* belong to the same *Publisher* can reduce the concurrency of the system because all the write operations will be serialized.

## 30.2 Creating Publishers

Before you can explicitly create a *Publisher*, you need a *DomainParticipant* (see [16.3 DomainParticipants on page 81](#)). To create a *Publisher*, use the *DomainParticipant*'s `create_publisher()` or `create_publisher_with_profile()` operations.

A QoS profile is way to use QoS settings from an XML file or string. With this approach, you can change QoS settings without recompiling the application. For details, see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

Note: The Modern C++ API Publishers provide constructors whose first and only required argument is the *DomainParticipant*.

```
DDSPublisher * create_publisher (
    const DDS_PublisherQos &qos,
    DDSPublisherListener *listener,
    DDS_StatusMask mask)
DDSPublisher * create_publisher_with_profile (
    const char *library_name,
    const char *profile_name,
    DDSPublisherListener *listener,
    DDS_StatusMask mask)
```

Where:

**qos**

If you want the default QoS settings (described in the API Reference HTML documentation), use `DDS_PUBLISHER_QOS_DEFAULT` for this parameter (see [Figure 30.2: Creating a Publisher with Default QoS Policies on the next page](#)).

If you want to customize any of the QoS Policies, supply a QoS structure (see [Figure 30.3: Creating a Publisher with Non-Default QoS Policies \(not from a profile\) on page 381](#)). The QoS structure for a *Publisher* is described in [Chapter 46 Publisher/Subscriber QoS Policies on page 740](#).

**Note:** If you use `DDS_PUBLISHER_QOS_DEFAULT`, it is not safe to create the *Publisher* while another thread may be simultaneously calling `set_default_publisher_qos()`.

<b>listener</b>	<p><i>Listeners</i> are callback routines. <i>Connex</i> uses them to notify your application when specific events (status changes) occur with respect to the <i>Publisher</i> or the <i>DataWriters</i> created by the <i>Publisher</i>.</p> <p>The <i>listener</i> parameter may be set to NULL if you do not want to install a <i>Listener</i>. If you use NULL, the <i>Listener</i> of the <i>DomainParticipant</i> to which the <i>Publisher</i> belongs will be used instead (if it is set). For more information on <i>PublisherListeners</i>, see <a href="#">30.5 Setting Up PublisherListeners on page 385</a>.</p>
<b>mask</b>	<p>This bit-mask indicates which status changes will cause the <i>Publisher's Listener</i> to be invoked. The bits set in the mask must have corresponding callbacks implemented in the <i>Listener</i>.</p> <p>If you use NULL for the <i>Listener</i>, use <code>DDS_STATUS_MASK_NONE</code> for this parameter. If the <i>Listener</i> implements all callbacks, use <code>DDS_STATUS_MASK_ALL</code>. For information on statuses, see <a href="#">15.8 Listeners on page 46</a>.</p>
<b>library_name</b>	<p>A QoS Library is a named set of QoS profiles. See <a href="#">50.2 QoS Profiles on page 906</a>. If NULL is used for <b>library_name</b>, the <i>DomainParticipant's</i> default library is assumed (see <a href="#">30.4.4 Getting and Setting the Publisher's Default QoS Profile and Library on page 383</a>).</p>
<b>profile_name</b>	<p>A QoS profile groups a set of related QoS, usually one per entity. See <a href="#">50.2 QoS Profiles on page 906</a>. If NULL is used for <b>profile_name</b>, the <i>DomainParticipant's</i> default profile is assumed and <b>library_name</b> is ignored.</p>

**Figure 30.2: Creating a Publisher with Default QoS Policies**

```
// create the publisher
DDSPublisher* publisher =
    participant->create_publisher(
        DDS_PUBLISHER_QOS_DEFAULT,
        NULL, DDS_STATUS_MASK_NONE);
if (publisher == NULL) {
    // handle error
};
```

For more examples, see [30.4.1 Configuring QoS Settings when the Publisher is Created on page 380](#).

After you create a *Publisher*, the next step is to use the *Publisher* to create a *DataWriter* for each *Topic*, see [31.1 Creating DataWriters on page 393](#). For a list of operations you can perform with a *Publisher*, see [Table 30.1 Publisher Operations](#).

## 30.3 Deleting Publishers

(Note: in the Modern C++ API, *Entities* are automatically destroyed, see [15.1 Creating and Deleting DDS Entities on page 33](#))

This section applies to both implicitly and explicitly created *Publishers*.

To delete a *Publisher*:

1. You must first delete all *DataWriters* that were created with the *Publisher*. Use the *Publisher's* `delete_datawriter()` operation to delete them one at a time, or use the `delete_contained_entities`

() operation ([30.3.1 Deleting Contained DataWriters below](#)) to delete them all at the same time.

```
DDS_ReturnCode_t delete_datawriter (DDSDataWriter *a_datawriter)
```

2. Delete the *Publisher* by using the *DomainParticipant*'s `delete_publisher()` operation.

```
DDS_ReturnCode_t delete_publisher (DDSPublisher *p)
```

**Note:** A *Publisher* cannot be deleted within a *Listener* callback, see [15.8.8.1 Restricted Operations in Listener Callbacks on page 57](#).

### 30.3.1 Deleting Contained DataWriters

The *Publisher*'s `delete_contained_entities()` operation deletes all the *DataWriters* that were created by the *Publisher*.

```
DDS_ReturnCode_t delete_contained_entities ()
```

After this operation returns successfully, the application may delete the *Publisher* (see [30.3 Deleting Publishers on the previous page](#)).

## 30.4 Setting Publisher QoS Policies

A *Publisher*'s QoS Policies control its behavior. Think of the policies as the configuration and behavior 'properties' of the *Publisher*. The **DDS\_PublisherQos** structure has the following format:

```
DDS_PublisherQos struct {
    DDS_PresentationQosPolicy presentation;
    DDS_PartitionQosPolicy partition;
    DDS_GroupDataQosPolicy group_data;
    DDS_EntityFactoryQosPolicy entity_factory;
    DDS_AsynchronousPublisherQosPolicy asynchronous_publisher;
    DDS_ExclusiveAreaQosPolicy exclusive_area;
    DDS_EntityNameQosPolicy publisher_name;
} DDS_PublisherQos;
```

**Note:** `set_qos()` cannot always be used in a listener callback; see [15.8.8.1 Restricted Operations in Listener Callbacks on page 57](#).

[Table 30.2 Publisher QoS Policies](#) summarizes the meaning of each policy. (They appear alphabetically in the table.) For information on *why* you would want to change a particular QoS Policy, see the referenced section. For defaults and valid ranges, please refer to the API Reference HTML documentation for each policy.

Table 30.2 Publisher QoS Policies

QoS Policy	Description
<a href="#">46.1 ASYNCHRONOUS_PUBLISHER QoS Policy (DDS Extension) on page 740</a>	Configures the mechanism that sends user data in an external middleware thread.
<a href="#">46.2 ENTITYFACTORY QoS Policy on page 743</a>	Controls whether or not child <i>Entities</i> are created in the enabled state.
<a href="#">47.11 ENTITY_NAME QoS Policy (DDS Extension) on page 817</a>	Assigns a <b>name</b> and <b>role_name</b> to a <i>Publisher</i> .
<a href="#">46.3 EXCLUSIVE_AREA QoS Policy (DDS Extension) on page 746</a>	Configures multi-thread concurrency and deadlock prevention capabilities.
<a href="#">46.4 GROUP_DATA QoS Policy on page 748</a>	Along with <a href="#">45.1 TOPIC_DATA QoS Policy on page 737</a> and <a href="#">47.30 USER_DATA QoS Policy on page 864</a> , this QoS Policy is used to attach a buffer of bytes to <i>Connex</i> 's discovery meta-data.
<a href="#">46.5 PARTITION QoS Policy on page 751</a>	Adds string identifiers that are used for matching <i>DataReaders</i> and <i>DataWriters</i> for the same <i>Topic</i> .
<a href="#">46.6 PRESENTATION QoS Policy on page 760</a>	Controls how <i>Connex</i> presents data received by an application to the <i>DataReaders</i> of the data.

### 30.4.1 Configuring QoS Settings when the Publisher is Created

As described in [30.2 Creating Publishers on page 377](#), there are different ways to create a *Publisher*, depending on how you want to specify its QoS (with or without a QoS Profile).

- In [Figure 30.2: Creating a Publisher with Default QoS Policies on page 378](#) we saw an example of how to explicitly create a *Publisher* with default QoS Policies. It used the special constant, **DDS\_PUBLISHER\_QOS\_DEFAULT**, which indicates that the default QoS values for a *Publisher* should be used. Default *Publisher* QoS Policies are configured in the *DomainParticipant*; you can change them with the *DomainParticipant*'s **set\_default\_publisher\_qos()** or **set\_default\_publisher\_qos\_with\_profile()** operation (see [16.3.7.5 Getting and Setting Default QoS for Child Entities on page 101](#)).
- To create a *Publisher* with non-default QoS settings, without using a QoS profile, see [Figure 30.3: Creating a Publisher with Non-Default QoS Policies \(not from a profile\) on the next page](#). It uses the *DomainParticipant*'s **get\_default\_publisher\_qos()** method to initialize a **DDS\_PublisherQos** structure. Then the policies are modified from their default values before the QoS structure is passed to **create\_publisher()**.
- You can also create a *Publisher* and specify its QoS settings via a QoS Profile. To do so, call **create\_publisher\_with\_profile()**, as seen in [Figure 30.4: Creating a Publisher with a QoS Profile on the next page](#).
- If you want to use a QoS profile, but then make some changes to the QoS before creating the *Publisher*, call the *DomainParticipantFactory*'s **get\_publisher\_qos\_from\_profile()**, modify the QoS and use the modified QoS structure when calling **create\_publisher()**, as seen in [Figure](#)

[30.5: Getting QoS Values from a Profile, Changing QoS Values, Creating a Publisher with Modified QoS Values on the next page.](#)

For more information, see [30.2 Creating Publishers on page 377](#) and [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

**Figure 30.3: Creating a Publisher with Non-Default QoS Policies (not from a profile)**

```
DDS_PublisherQos publisher_qos;1
// get defaults
if (participant->get_default_publisher_qos(publisher_qos) != DDS_RETCODE_OK) {
    // handle error
}
// make QoS changes here
// for example, this changes the ENTITY_FACTORY QoS
publisher_qos.entity_factory.autoenable_created_entities = DDS_BOOLEAN_FALSE;
// create the publisher
DDSPublisher* publisher = participant->create_publisher(publisher_qos,
    NULL, DDS_STATUS_MASK_NONE);
if (publisher == NULL) {
    // handle error
}
```

**Figure 30.4: Creating a Publisher with a QoS Profile**

```
// create the publisher with QoS profile
DDSPublisher* publisher = participant->create_publisher_with_profile(
    "MyPublisherLibrary", "MyPublisherProfile",
    NULL, DDS_STATUS_MASK_NONE);
if (publisher == NULL) {
    // handle error
}
```

**Figure 30.5: Getting QoS Values from a Profile, Changing QoS Values, Creating a Publisher with Modified QoS Values**

```
DDS_PublisherQos publisher_qos;2
// Get publisher QoS from profile
retcode = factory->get_publisher_qos_from_profile(publisher_qos,
    "PublisherLibrary", "PublisherProfile");
if (retcode != DDS_RETCODE_OK) {
    // handle error
}
// Makes QoS changes here
// New entity_factory autoenable_created_entities will be true
```

<sup>1</sup>For the C API, you need to use `DDS_PublisherQos_INITIALIZER` or `DDS_PublisherQos_initialize()`. See [42.2 Special QoS Policy Handling Considerations for C on page 688](#)

<sup>2</sup>For the C API, you need to use `DDS_PublisherQos_INITIALIZER` or `DDS_PublisherQos_initialize()`. See [42.2 Special QoS Policy Handling Considerations for C on page 688](#)

```

publisher_qos.entity_factory.autoenable_created_entities = DDS_BOOLEAN_TRUE;
// create the publisher with modified QoS
DDSPublisher* publisher = participant->create_publisher(
    "Example Foo", type_name, publisher_qos,
    NULL, DDS_STATUS_MASK_NONE);
if (publisher == NULL) {
    // handle error
}

```

## 30.4.2 Comparing QoS Values

The `equals()` operation compares two *Publisher's* `DDS_PublisherQoS` structures for equality. It takes two parameters for the two *Publisher's* QoS structures to be compared, then returns `TRUE` if they are equal (all values are the same) or `FALSE` if they are not equal.

## 30.4.3 Changing QoS Settings After the Publisher Has Been Created

There are 2 ways to change an existing *Publisher's* QoS after it has been created—again depending on whether or not you are using a QoS Profile.

- To change an existing *Publisher's* QoS programmatically (that is, without using a QoS profile): `get_qos()` and `set_qos()`. See the example code in [Figure 30.6: Changing the QoS of an Existing Publisher below](#). It retrieves the current values by calling the *Publisher's* `get_qos()` operation. Then it modify the value and call `set_qos()` to apply the new value. Note, however, that some QoS Policies cannot be changed after the *Publisher* has been enabled—this restriction is noted in the descriptions of the individual QoS Policies.
- You can also change a *Publisher's* (and all other *Entities'*) QoS by using a QoS Profile and calling `set_qos_with_profile()`. For an example, see [Figure 30.7: Changing the QoS of an Existing Publisher with a QoS Profile on the next page](#). For more information, see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

**Figure 30.6: Changing the QoS of an Existing Publisher**

```

DDS_PublisherQos publisher_qos;1
// Get current QoS. publisher points to an existing DDSPublisher.
if (publisher->get_qos(publisher_qos) != DDS_RETCODE_OK) {
    // handle error
}
// make changes
// New entity_factory autoenable_created_entities will be true
publisher_qos.entity_factory.autoenable_created_entities = DDS_BOOLEAN_TRUE;
// Set the new QoS
if (publisher->set_qos(publisher_qos) != DDS_RETCODE_OK ) {
    // handle error
}

```

<sup>1</sup>For the C API, you need to use `DDS_PublisherQos_INITIALIZER` or `DDS_PublisherQos_initialize()`. See [42.2 Special QoS Policy Handling Considerations for C on page 688](#)

Figure 30.7: Changing the QoS of an Existing Publisher with a QoS Profile

```
retcode = publisher->set_qos_with_profile(
    "PublisherProfileLibrary", "PublisherProfile");
if (retcode != DDS_RETCODE_OK) {
    // handle error
}
```

### 30.4.4 Getting and Setting the Publisher's Default QoS Profile and Library

You can retrieve the default QoS profile used to create *Publishers* with the `get_default_profile()` operation.

You can also get the default library for *Publishers*, as well as the library that contains the *Publisher's* default profile (these are not necessarily the same library); these operations are called `get_default_library()` and `get_default_library_profile()`, respectively. These operations are for informational purposes only (that is, you do not need to use them as a precursor to setting a library or profile.) For more information, see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

```
virtual const char * get_default_library ()
const char * get_default_profile ()
const char * get_default_profile_library ()
```

There are also operations for setting the *Publisher's* default library and profile:

```
DDS_ReturnCode_t set_default_library (const char * library_name)
DDS_ReturnCode_t set_default_profile (const char * library_name,
    const char * profile_name)
```

These operations only affect which library/profile will be used as the default the next time a default *Publisher* library/profile is needed during a call to one of this *Publisher's* operations.

When calling a *Publisher* operation that requires a **profile\_name** parameter, you can use NULL to refer to the default profile. (This same information applies to setting a default library.) If the default library/profile is not set, the *Publisher* inherits the default from the *DomainParticipant*.

`set_default_profile()` does not set the default QoS for *DataWriters* created by the *Publisher*; for this functionality, use the *Publisher's* `set_default_datawriter_qos_with_profile()`, see [30.4.5 Getting and Setting Default QoS for DataWriters below](#) (you may pass in NULL aftercalling the *Publisher's* `set_default_profile()`).

`set_default_profile()` does not set the default QoS for newly created *Publishers*; for this functionality, use the *DomainParticipant's* `set_default_publisher_qos_with_profile()` operation, see [16.3.7.5 Getting and Setting Default QoS for Child Entities on page 101](#).

### 30.4.5 Getting and Setting Default QoS for DataWriters

These operations set the default QoS that will be used for new *DataWriters* if `create_datawriter()` is called with `DDS_DATAWRITER_QOS_DEFAULT` as the **qos** parameter:

```
DDS_ReturnCode_t set_default_datawriter_qos (const DDS_DataWriterQos &qos)
DDS_ReturnCode_t set_default_datawriter_qos_with_profile (
    const char *library_name,
    const char *profile_name)
```

The above operations may potentially allocate memory, depending on the sequences contained in some QoS policies.

To get the default QoS that will be used for creating *DataWriters* if **create\_datawriter()** is called with `DDS_PARTICIPANT_QOS_DEFAULT` as the **qos** parameter:

```
DDS_ReturnCode_t get_default_datawriter_qos (DDS_DataWriterQos & qos)
```

This operation gets the QoS settings that were specified on the last successful call to **set\_default\_datawriter\_qos()** or **set\_default\_datawriter\_qos\_with\_profile()**, or if the call was never made, the default values listed in `DDS_DataWriterQos`.

**Note:** It is not safe to set the default *DataWriter* QoS values while another thread may be simultaneously calling **get\_default\_datawriter\_qos()**, **set\_default\_datawriter\_qos()**, or **create\_datawriter()** with `DDS_DATAWRITER_QOS_DEFAULT` as the **qos** parameter. It is also not safe to get the default *DataWriter* QoS values while another thread may be simultaneously calling **set\_default\_datawriter\_qos()**.

## 30.4.6 Other Publisher QoS-Related Operations

- **Copying a Topic’s QoS into a DataWriter’s QoS**

This method is provided as a convenience for setting the values in a *DataWriterQos* structure before using that structure to create a *DataWriter*. As explained in [18.1.3 Setting Topic QoS Policies on page 250](#), most of the policies in a *TopicQos* structure do not apply directly to the *Topic* itself, but to the associated *DataWriters* and *DataReaders* of that *Topic*. The *TopicQos* serves as a single container where the values of QoS Policies that must be set compatibly across matching *DataWriters* and *DataReaders* can be stored.

Thus instead of setting the values of the individual QoS Policies that make up a *DataWriterQos* structure every time you need to create a *DataWriter* for a *Topic*, you can use the *Publisher’s* **copy\_from\_topic\_qos()** operation to “import” the *Topic’s* QoS Policies into a *DataWriterQos* structure. This operation copies the relevant policies in the *TopicQos* to the corresponding policies in the *DataWriterQos*.

This copy operation will often be used in combination with the *Publisher’s* **get\_default\_datawriter\_qos()** and the *Topic’s* **get\_qos()** operations. The *Topic’s* QoS values are merged on top of the *Publisher’s* default *DataWriter* QoS Policies with the result used to create a new *DataWriter*, or to set the QoS of an existing one (see [31.15 Setting DataWriter QoS Policies on page 433](#)).

- **Copying a Publisher's QoS**

C API users should use the `DDS_PublisherQos_copy()` operation rather than using structure assignment when copying between two QoS structures. The `copy()` operation will perform a deep copy so that policies that allocate heap memory such as sequences are copied correctly. In C++, C# and Java, a copy constructor is provided to take care of sequences automatically.

- **Clearing QoS-Related Memory**

Some QoS policies contain sequences that allocate memory dynamically as they grow or shrink. The C API's `DDS_PublisherQos_finalize()` operation frees the memory used by sequences but otherwise leaves the QoS unchanged. C API users should call `finalize()` on all `DDS_PublisherQos` objects before they are freed, or for QoS structures allocated on the stack, before they go out of scope. In C++, C# and Java, the memory used by sequences is freed in the destructor.

## 30.5 Setting Up PublisherListeners

Like all *Entities*, *Publishers* may optionally have *Listeners*. *Listeners* are user-defined objects that implement a DDS-defined interface (i.e. a pre-defined set of callback functions). *Listeners* provide the means for *Connex*t to notify applications of any changes in *Statuses* (events) that may be relevant to it. By writing the callback functions in the *Listener* and installing the *Listener* into the *Publisher*, applications can be notified to handle the events of interest. For more general information on *Listeners* and *Statuses*, see [15.8 Listeners on page 46](#).

**Note:** Some operations cannot be used within a listener callback, see [15.8.8.1 Restricted Operations in Listener Callbacks on page 57](#).

As illustrated in [Figure 30.1: Publication Module on page 374](#), the *PublisherListener* interface extends the *DataWriterListener* interface. In other words, the *PublisherListener* interface contains all the functions in the *DataWriterListener* interface. There are no *Publisher*-specific *statuses*, and thus there are no *Publisher*-specific functions.

Instead, the methods of a *PublisherListener* will be called back for changes in the *Statuses* of any of the *DataWriters* that the *Publisher* has created. This is only true if the *DataWriter* itself does not have a *DataWriterListener* installed, see [31.4 Setting Up DataWriterListeners on page 395](#). If a *DataWriterListener* has been installed and has been enabled to handle a *Status* change for the *DataWriter*, then *Connex*t will call the method of the *DataWriterListener* instead.

If you want a *Publisher* to handle status events for its *DataWriters*, you can set up a *PublisherListener* during the *Publisher*'s creation or use the `set_listener()` method after the *Publisher* is created. The last parameter is a bit-mask with which you should set which *Status* events that the *PublisherListener* will handle. For example,

```
DDS_StatusMask mask = DDS_OFFERED_DEADLINE_MISSED_STATUS |
                      DDS_OFFERED_INCOMPATIBLE_QOS_STATUS;
publisher = participant->create_publisher(
    DDS_PUBLISHER_QOS_DEFAULT, listener, mask);
```

or

```
DDS_StatusMask mask = DDS_OFFERED_DEADLINE_MISSED_STATUS |
                      DDS_OFFERED_INCOMPATIBLE_QOS_STATUS;
publisher->set_listener(listener, mask);
```

As previously mentioned, the callbacks in the *PublisherListener* act as ‘default’ callbacks for all the *DataWriters* contained within. When *Connex* wants to notify a *DataWriter* of a relevant *Status* change (for example, `PUBLICATION_MATCHED`), it first checks to see if the *DataWriter* has the corresponding *DataWriterListener* callback enabled (such as the `on_publication_matched()` operation). If so, *Connex* dispatches the event to the *DataWriterListener* callback. Otherwise, *Connex* dispatches the event to the corresponding *PublisherListener* callback.

A particular callback in a *DataWriter* is *not* enabled if either:

- The application installed a NULL *DataWriterListener* (meaning there are *no* callbacks for the *DataWriter* at all).
- The application has disabled the callback for a *DataWriterListener*. This is done by turning off the associated status bit in the *mask* parameter passed to the `set_listener()` or `create_datawriter()` call when installing the *DataWriterListener* on the *DataWriter*. For more information on *DataWriterListeners*, see [31.4 Setting Up DataWriterListeners on page 395](#).

Similarly, the callbacks in the *DomainParticipantListener* act as ‘default’ callbacks for all the *Publishers* that belong to it. For more information on *DomainParticipantListeners*, see [16.3.6 Setting Up DomainParticipantListeners on page 94](#).

For example, [Figure 30.8: Example Code to Create a Publisher with a Simple Listener below](#) shows how to create a *Publisher* with a *Listener* that simply prints the events it receives.

**Figure 30.8: Example Code to Create a Publisher with a Simple Listener**

```
class MyPublisherListener : public DDSPublisherListener {
public:
    virtual void on_offered_deadline_missed(
        DDSDataWriter* writer,
        const DDS_OfferedDeadlineMissedStatus& status);
    virtual void on_liveliness_lost(
        DDSDataWriter* writer,
        const DDS_LivelinessLostStatus& status);
    virtual void on_offered_incompatible_qos(
        DDSDataWriter* writer,
        const DDS_OfferedIncompatibleQosStatus& status);
    virtual void on_publication_matched(
        DDSDataWriter* writer,
        const DDS_PublicationMatchedStatus& status);
    virtual void on_reliable_writer_cache_changed(
```

```

    DDSDataWriter* writer,
        const DDS_ReliableWriterCacheChangedStatus& status);
virtual void on_reliable_reader_activity_changed (
    DDSDataWriter* writer,
    const DDS_ReliableReaderActivityChangedStatus& status);
};
void MyPublisherListener::on_offered_deadline_missed(
    DDSDataWriter* writer,
    const DDS_OfferedDeadlineMissedStatus& status)
{
    printf("on_offered_deadline_missed\n");
}
// ...Implement all remaining listeners in a similar manner...
DDSPublisherListener *myPubListener = new MyPublisherListener();
DDSPublisher* publisher =
    participant->create_publisher(DDS_PUBLISHER_QOS_DEFAULT,
        myPubListener, DDS_STATUS_MASK_ALL);

```

## 30.6 Finding a Publisher's Related DDS Entities

These *Publisher* operations are useful for obtaining a handle to related *Entities*:

- **get\_participant()**: Gets the *DomainParticipant* with which a *Publisher* was created.
- **lookup\_datawriter()**: Finds a *DataWriter* created by the *Publisher* with a *Topic* of a particular name. Note that in the event that multiple *DataWriters* were created by the same *Publisher* with the same *Topic*, any one of them may be returned by this method. (In the Modern C++ API this method is a freestanding function, **dds::pub::find()**)
- **DDS\_Publisher\_as\_Entity()**: This method is provided for C applications and is necessary when invoking the parent class *Entity* methods on *Publishers*. For example, to call the *Entity* method **get\_status\_changes()** on a *Publisher*, *my\_pub*, do the following:

```
DDS_Entity_get_status_changes(DDS_Publisher_as_Entity(my_pub))
```

**DDS\_Publisher\_as\_Entity()** is not provided in the C++, C# and Java APIs because the object-oriented features of those languages make it unnecessary.

## 30.7 Waiting for Acknowledgments in a Publisher

The *Publisher's* **wait\_for\_acknowledgments()** operation blocks the calling thread until either all data written by the *Publisher's* reliable *DataWriters* is acknowledged or the duration specified by the **max\_wait** parameter elapses, whichever happens first.

Note that if a thread is blocked in the call to **wait\_for\_acknowledgments()** on a *Publisher* and a different thread writes new DDS samples on any of the *Publisher's* reliable *DataWriters*, the new DDS samples must be acknowledged before unblocking the thread that is waiting on **wait\_for\_acknowledgments()**.

```
DDS_ReturnCode_t wait_for_acknowledgments (const DDS_Duration_t & max_wait)
```

This operation returns **DDS\_RETCODE\_OK** if all the DDS samples were acknowledged, or **DDS\_RETCODE\_TIMEOUT** if the **max\_wait** duration expired first.

There is a similar operation available for individual *DataWriters*, see [31.11 Waiting for Acknowledgments in a DataWriter on page 417](#).

The reliability protocol used by *Connex* is discussed in [Reliability Models for Sending Data \(Chapter 32 on page 446\)](#).

## 30.8 Statuses for Publishers

There are no statuses specific to the Publisher itself. The following statuses can be monitored by the *PublisherListener* for the *Publisher's DataWriters*.

- [31.6.5 OFFERED\\_DEADLINE\\_MISSED Status on page 404](#)
- [31.6.4 LIVELINESS\\_LOST Status on page 403](#)
- [31.6.6 OFFERED\\_INCOMPATIBLE\\_QOS Status on page 404](#)
- [31.6.7 PUBLICATION\\_MATCHED Status on page 405](#)
- [31.6.8 RELIABLE\\_WRITER\\_CACHE\\_CHANGED Status \(DDS Extension\) on page 406](#)
- [31.6.9 RELIABLE\\_READER\\_ACTIVITY\\_CHANGED Status \(DDS Extension\) on page 408](#)

## 30.9 Suspending and Resuming Publications

The operations **suspend\_publications()** and **resume\_publications()** provide a *hint* to *Connex* that multiple data-objects within the Publisher are about to be written. *Connex* does not currently use this hint.

# Chapter 31 DataWriters

To create a *DataWriter*, you need a *DomainParticipant* and a *Topic*.

You need a *DataWriter* for each *Topic* that you want to publish. Once you have a *DataWriter*, you can use it to perform the operations listed in [Table 31.1 DataWriter Operations](#). The most important operation is `write()`, described in [31.8 Writing Data on page 410](#). For more details on all operations, see the API Reference HTML documentation.

*DataWriters* are created by using operations on a *DomainParticipant* or a *Publisher*, as described in [31.1 Creating DataWriters on page 393](#). If you use the *DomainParticipant*'s operations, the *DataWriter* will belong to an implicit *Publisher* that is automatically created by the middleware. If you use a *Publisher*'s operations, the *DataWriter* will belong to that *Publisher*. So either way, the *DataWriter* belongs to a *Publisher*.

**Note:** Some operations cannot be used within a listener callback, see [15.8.8.1 Restricted Operations in Listener Callbacks on page 57](#).

Table 31.1 DataWriter Operations

Working with ...	Operation	Description	Reference
DataWriters	assert_liveliness	Manually asserts the liveliness of the <i>DataWriter</i> .	<a href="#">31.17 Asserting Liveliness on page 444</a>
	enable	Enables the <i>DataWriter</i> .	<a href="#">15.2 Enabling DDS Entities on page 35</a>
	equals	Compares two <i>DataWriter</i> 's QoS structures for equality.	<a href="#">31.15.2 Comparing QoS Values on page 439</a>
	get_qos	Gets the QoS.	<a href="#">31.15 Setting DataWriter QoS Policies on page 433</a>
	lookup_instance	Gets a handle, given an instance. (Useful for keyed data types only.)	<a href="#">31.14.5 Looking up an Instance Handle on page 430</a>
	set_qos	Modifies the QoS.	<a href="#">31.15 Setting DataWriter QoS Policies on page 433</a>
	set_qos_with_profile	Modifies the QoS based on a QoS profile.	<a href="#">31.15 Setting DataWriter QoS Policies on page 433</a>
	get_listener	Gets the currently installed Listener.	<a href="#">31.4 Setting Up DataWriter-Listeners on page 395</a>
	set_listener	Replaces the Listener.	

Table 31.1 DataWriter Operations

Working with ...	Operation	Description	Reference
FooDataWriter (See <a href="#">31.7 Using a Type-Specific DataWriter (FooDataWriter)</a> on page 409)	dispose	States that the instance no longer exists. (Useful for keyed data types only.)	<a href="#">31.14.3 Disposing Instances</a> on page 428
	dispose_w_timestamp	Same as dispose, but allows the application to override the automatic source_timestamp. (Useful for keyed data types only.)	
	flush	Makes the batch available to be sent on the network.	<a href="#">31.9 Flushing Batches of DDS Data Samples</a> on page 416
	get_key_value	Maps an instance_handle to the corresponding key.	<a href="#">31.14.6 Getting the Key Value for an Instance</a> on page 430
	narrow	A type-safe way to cast a pointer. This takes a DDSDataWriter pointer and 'narrows' it to a 'FooDataWriter' where 'Foo' is the related data type.	<a href="#">31.7 Using a Type-Specific DataWriter (FooDataWriter)</a> on page 409
	register_instance	States the intent of the <i>DataWriter</i> to write values of the data-instance that matches a specified key. Improves the performance of subsequent writes to the instance. (Useful for keyed data types only.)	<a href="#">31.14.2 Registering Instances</a> on page 426 and <a href="#">31.14.4 Unregistering Instances</a> on page 429
	register_instance_w_timestamp	Like register_instance, but allows the application to override the automatic source_timestamp. (Useful for keyed data types only.)	
	unregister_instance	Reverses register_instance. Relinquishes the ownership of the instance. (Useful for keyed data types only.)	
	unregister_instance_w_timestamp	Like unregister_instance, but allows the application to override the automatic source_timestamp. (Useful for keyed data types only.)	
	write	Writes a new value for a data-instance.	<a href="#">31.8 Writing Data</a> on page 410
write_w_timestamp	Same as write, but allows the application to override the automatic source_timestamp.		
FooDataWriter (See <a href="#">31.7 Using a Type-Specific DataWriter (FooDataWriter)</a> on page 409)	write_w_params	Same as write, but allows the application to specify parameters such as source_timestamp and instance handle.	<a href="#">31.8 Writing Data</a> on page 410
	dispose_w_params	Same as dispose, but allows the application to specify parameters such as source_timestamp and instance handle..	<a href="#">31.14.3 Disposing Instances</a> on page 428
	register_w_params	Same as register, but allows the application to specify parameters such as source_timestamp, instance handle.	<a href="#">31.14.2 Registering Instances</a> on page 426 and <a href="#">31.14.4 Unregistering Instances</a> on page 429
	unregister_w_params	Same as unregister, but allows the application to specify parameters such as source_timestamp, and instance handle.	

Table 31.1 DataWriter Operations

Working with ...	Operation	Description	Reference
Matched Subscriptions	get_matched_subscriptions	Gets a list of subscriptions that have a matching <i>Topic</i> and compatible QoS. These are the subscriptions currently associated with the <i>DataWriter</i> .	31.16.1 Finding Matching Subscriptions on page 442
	get_matched_subscription_data	Gets information on a subscription with a matching <i>Topic</i> and compatible QoS.	
	get_matched_subscription_locators	Gets a list of locators for subscriptions that have a matching <i>Topic</i> and compatible QoS. These are the subscriptions currently associated with the <i>DataWriter</i> .	
	get_matched_subscription_participant_data	Gets information about the <i>DomainParticipant</i> of a matching subscription.	31.16.2 Finding the Matching Subscription's ParticipantBuiltinTopicData on page 443
	is_matched_subscription_active	Enables you to query whether the matched <i>DataReader</i> (identified using the instance handle returned by <b>get_matched_subscriptions</b> ) is active. <b>get_matched_subscriptions</b> returns all matching <i>DataReaders</i> , including those that are not active. This operation enables you to see which matching <i>DataReaders</i> are active.	31.16.1 Finding Matching Subscriptions on page 442
Status	get_status_changes	Gets a list of statuses that have changed since the last time the application read the status or the listeners were called.	15.4 Getting Status and Status Changes on page 38
	get_liveliness_lost_status	Gets LIVELINESS_LOST status.	31.6 Statuses for DataWriters on page 397
	get_offered_deadline_missed_status	Gets OFFERED_DEADLINE_MISSED status.	
	get_offered_incompatible_qos_status	Gets OFFERED_INCOMPATIBLE_QOS status.	
	get_publication_match_status	Gets PUBLICATION_MATCHED_QOS status.	

Table 31.1 DataWriter Operations

Working with ...	Operation	Description	Reference
Status cont'd	get_reliable_writer_cache_changed_status	Gets RELIABLE_WRITER_CACHE_CHANGED status	
	get_reliable_reader_activity_changed_status	Gets RELIABLE_READER_ACTIVITY_CHANGED status	
	get_datawriter_cache_status	Gets DATA_WRITER_CACHE_status	
	get_datawriter_protocol_status	Gets DATA_WRITER_PROTOCOL status	
	get_matched_subscription_datawriter_protocol_status	Gets DATA_WRITER_PROTOCOL status for this <i>DataWriter</i> , per matched subscription identified by the subscription_handle.	31.6 Statuses for DataWriters on page 397
	get_matched_subscription_datawriter_protocol_status_by_locator	Gets DATA_WRITER_PROTOCOL status for this <i>DataWriter</i> , per matched subscription as identified by a locator.	
Other	get_publisher	Gets the <i>Publisher</i> to which the <i>DataWriter</i> belongs.	31.16.3 Finding Related DDS Entities on page 444
	get_topic	Get the Topic associated with the <i>DataWriter</i> .	
	wait_for_acknowledgements	Blocks the calling thread until either all data written by the <i>DataWriter</i> is acknowledged by all matched Reliable <i>DataReaders</i> , or until the a specified timeout duration, max_wait, elapses.	31.11 Waiting for Acknowledgments in a <i>DataWriter</i> on page 417

## 31.1 Creating DataWriters

Before you can create a *DataWriter*, you need a *DomainParticipant*, a *Topic*, and optionally, a *Publisher*.

*DataWriters* are created by calling `create_datawriter()` or `create_datawriter_with_profile()`—these operations exist for *DomainParticipants* and *Publishers*. If you use the *DomainParticipant* to create a *DataWriter*, it will belong to the implicit *Publisher* described in [30.1 Creating Publishers Explicitly vs. Implicitly on page 376](#). If you use a *Publisher*'s operations to create a *DataWriter*, it will belong to that *Publisher*.

A *QoS profile* is way to use QoS settings from an XML file or string. With this approach, you can change QoS settings without recompiling the application. For details, see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

Note: In the Modern C++ API *DataWriters* provide constructors whose first argument is a *Publisher*. The only required arguments are the publisher and the topic.

```

DDSDataWriter* create_datawriter (
    DDSTopic *topic,
    const DDS_DataWriterQos &qos,
    DDSDataWriterListener *listener,
    DDS_StatusMask mask)
DDSDataWriter * create_datawriter_with_profile(
    DDSTopic * topic,
    const char * library_name,
    const char * profile_name,
    DDSDataWriterListener * listener,
    DDS_StatusMask mask)

```

Where:

<b>topic</b>	The <i>Topic</i> that the <i>DataWriter</i> will publish. This must have been previously created by the same <i>DomainParticipant</i> .
<b>qos</b>	If you want the default QoS settings (described in the API Reference HTML documentation), use the constant <code>DDS_DATAWRITER_QOS_DEFAULT</code> for this parameter (see <a href="#">Figure 31.1: Creating a DataWriter with Default QoS Policies and a Listener below</a> ). If you want to customize any of the QoS Policies, supply a QoS structure (see <a href="#">31.15 Setting DataWriter QoS Policies on page 433</a> ).  <b>Note:</b> If you use <code>DDS_DATAWRITER_QOS_DEFAULT</code> for the <b>qos</b> parameter, it is not safe to create the <i>DataWriter</i> while another thread may be simultaneously calling the <i>Publisher's</i> <code>set_default_datawriter_qos()</code> operation.
<b>listener</b>	<i>Listeners</i> are callback routines. <i>Connex</i> uses them to notify your application of specific events (status changes) that may occur with respect to the <i>DataWriter</i> . The <i>listener</i> parameter may be set to NULL; in this case, the <i>PublisherListener</i> (or if that is NULL, the <i>DomainParticipantListener</i> ) will be used instead. For more information, see <a href="#">31.4 Setting Up DataWriterListeners on the next page</a>
<b>mask</b>	This bit-mask indicates which status changes will cause the <i>Listener</i> to be invoked. The bits set in the mask must have corresponding callbacks implemented in the <i>Listener</i> . If you use NULL for the <i>Listener</i> , use <code>DDS_STATUS_MASK_NONE</code> for this parameter. If the <i>Listener</i> implements all callbacks, use <code>DDS_STATUS_MASK_ALL</code> . For information on statuses, see <a href="#">15.8 Listeners on page 46</a> .
<b>library_name</b>	A QoS Library is a named set of QoS profiles. See <a href="#">50.2 QoS Profiles on page 906</a> .
<b>profile_name</b>	A QoS profile groups a set of related QoS, usually one per entity. See <a href="#">50.2 QoS Profiles on page 906</a> .

For more examples on how to create a *DataWriter*, see [31.15.1 Configuring QoS Settings when the DataWriter is Created on page 437](#)

After you create a *DataWriter*, you can use it to write data. See [31.8 Writing Data on page 410](#).

**Note:** When a *DataWriter* is created, only those transports already registered are available to the *DataWriter*. The built-in transports are implicitly registered when (a) the *DomainParticipant* is enabled, (b) the first *DataWriter* is created, or (c) you look up a built-in data reader, whichever happens first.

**Figure 31.1: Creating a DataWriter with Default QoS Policies and a Listener**

```

// MyWriterListener is user defined, extends DDSDataWriterListener
DDSDataWriterListener* writer_listener = new MyWriterListener();
DDSDataWriter* writer = publisher->create_datawriter(
    topic,
    DDS_DATAWRITER_QOS_DEFAULT,
    writer_listener,

```

```

DDS_STATUS_MASK_ALL);
if (writer == NULL) {
    // ... error
};
// narrow it for your specific data type
FooDataWriter* foo_writer = FooDataWriter::narrow(writer);

```

## 31.2 Getting All DataWriters

To retrieve all the *DataWriters* created by the *Publisher*, use the *Publisher's* `get_all_datawriters()` operation:

```

DDS_ReturnCode_t get_all_datawriters(DDS_Publisher* self,
                                     struct DDS_DataWriterSeq* writers);

```

In the Modern C++ API, use the freestanding function `rti::pub::find_datawriters()`.

## 31.3 Deleting DataWriters

(Note: in the Modern C++ API, *Entities* are automatically destroyed, see [15.1 Creating and Deleting DDS Entities on page 33](#))

To delete a single *DataWriter*, use the *Publisher's* `delete_datawriter()` operation:

```

DDS_ReturnCode_t delete_datawriter (
    DDSDataWriter *a_datawriter)

```

**Note:** A *DataWriter* cannot be deleted within its own writer listener callback, see [15.8.8.1 Restricted Operations in Listener Callbacks on page 57](#)

To delete all of a *Publisher's* *DataWriters*, use the *Publisher's* `delete_contained_entities()` operation (see [30.3.1 Deleting Contained DataWriters on page 379](#)).

## 31.4 Setting Up DataWriterListeners

*DataWriters* may optionally have *Listeners*. *Listeners* are essentially callback routines and provide the means for *Connex* to notify your application of the occurrence of events (status changes) relevant to the *DataWriter*. For more general information on *Listeners*, see [15.8 Listeners on page 46](#).

**Note:** Some operations cannot be used within a listener callback, see [15.8.8.1 Restricted Operations in Listener Callbacks on page 57](#).

If you do not implement a *DataWriterListener*, the associated *PublisherListener* is used instead. If that *Publisher* also does not have a *Listener*, then the *DomainParticipant's Listener* is used if one exists (see [30.5 Setting Up PublisherListeners on page 385](#) and [16.3.6 Setting Up DomainParticipantListeners on page 94](#)).

*Listeners* are typically set up when the *DataWriter* is created (see [Chapter 30 Publishers on page 373](#)). You can also set one up after creation by using the `set_listener()` operation. *Connex* will invoke a *DataWriter's Listener* to report the status changes listed in [Table 31.2 DataWriterListener Callbacks](#) (if

the Listener is set up to handle the particular status, see [31.4 Setting Up DataWriterListeners on the previous page](#)).

**Table 31.2 DataWriterListener Callbacks**

This DataWriterListener callback...	... is triggered by ...
on_instance_replaced()	A replacement of an existing instance by a new instance; see <a href="#">47.6.1 Configuring DataWriter Instance Replacement on page 802</a>
on_liveliness_lost	A change to <a href="#">31.6.4 LIVELINESS_LOST Status on page 403</a>
on_offered_deadline_missed	A change to <a href="#">31.6.5 OFFERED_DEADLINE_MISSED Status on page 404</a>
on_offered_incompatible_qos	A change to <a href="#">31.6.6 OFFERED_INCOMPATIBLE_QOS Status on page 404</a>
on_publication_matched	A change to <a href="#">31.6.7 PUBLICATION_MATCHED Status on page 405</a>
on_reliable_writer_cache_changed	A change to <a href="#">31.6.8 RELIABLE_WRITER_CACHE_CHANGED Status (DDS Extension) on page 406</a>
on_reliable_reader_activity_changed	A change to <a href="#">31.6.9 RELIABLE_READER_ACTIVITY_CHANGED Status (DDS Extension) on page 408</a>
on_sample_removed	Removal of a sample from the <i>DataWriter</i> queue, when the sample was written with a cookie using the <code>write_w_params</code> API or if the <i>DataWriter</i> supports loaned samples, which are used by Zero Copy over shared memory and FlatData language binding (see <a href="#">Chapter 34 Sending Large Data on page 497</a> )
on_application_acknowledgment	Application acknowledgment (see <a href="#">31.6.1 APPLICATION_ACKNOWLEDGMENT_STATUS on page 398</a> )
on_service_request_accepted	A change to <a href="#">31.6.10 SERVICE_REQUEST_ACCEPTED Status (DDS Extension) on page 408</a> .

## 31.5 Checking DataWriter Status

You can access an individual communication status for a *DataWriter* with the operations shown in [Table 31.3 DataWriter Status Operations](#).

**Table 31.3 DataWriter Status Operations**

Use this operation...	...to retrieve this status:
<code>get_datawriter_cache_status</code>	<a href="#">31.6.2 DATA_WRITER_CACHE_STATUS on the next page</a>
<code>get_datawriter_protocol_status</code>	<a href="#">31.6.3 DATA_WRITER_PROTOCOL_STATUS on page 399</a>
<code>get_matched_subscription_datawriter_protocol_status</code>	
<code>get_matched_subscription_datawriter_protocol_status_by_locator</code>	
<code>get_liveliness_lost_status</code>	<a href="#">31.6.4 LIVELINESS_LOST Status on page 403</a>
<code>get_offered_deadline_missed_status</code>	<a href="#">31.6.5 OFFERED_DEADLINE_MISSED Status on page 404</a>
<code>get_offered_incompatible_qos_status</code>	<a href="#">31.6.6 OFFERED_INCOMPATIBLE_QOS Status on page 404</a>
<code>get_publication_match_status</code>	<a href="#">31.6.7 PUBLICATION_MATCHED Status on page 405</a>
<code>get_reliable_writer_cache_changed_status</code>	<a href="#">31.6.8 RELIABLE_WRITER_CACHE_CHANGED Status (DDS Extension) on page 406</a>
<code>get_reliable_reader_activity_changed_status</code>	<a href="#">31.6.9 RELIABLE_READER_ACTIVITY_CHANGED Status (DDS Extension) on page 408</a>
<code>get_service_request_accepted_status</code>	<a href="#">31.6.10 SERVICE_REQUEST_ACCEPTED Status (DDS Extension) on page 408</a>
<code>get_status_changes</code>	A list of what changed in all of the above.

These methods are useful in the event that no *Listener* callback is set to receive notifications of status changes. If a *Listener* is used, the callback will contain the new status information, in which case calling these methods is unlikely to be necessary.

The `get_status_changes()` operation provides a list of statuses that have changed since the last time the status changes were ‘reset.’ A status change is reset each time the application calls the corresponding `get_*_status()`, as well as each time *Connex* returns from calling the *Listener* callback associated with that status.

For more on status, see [31.4 Setting Up DataWriterListeners on page 395](#), [31.6 Statuses for DataWriters below](#), and [15.8 Listeners on page 46](#).

## 31.6 Statuses for DataWriters

There are several types of statuses available for a *DataWriter*. You can use the `get_*_status()` operations ([31.15 Setting DataWriter QoS Policies on page 433](#)) to access them, or use a *DataWriterListener* ([31.4 Setting Up DataWriterListeners on page 395](#)) to listen for changes in their values. Each status has an associated data structure and is described in more detail in the following sections.

- [31.6.1 APPLICATION\\_ACKNOWLEDGMENT\\_STATUS on the next page](#)
- [31.6.2 DATA\\_WRITER\\_CACHE\\_STATUS on the next page](#)

- [31.6.3 DATA\\_WRITER\\_PROTOCOL\\_STATUS](#) on the next page
- [31.6.4 LIVELINESS\\_LOST](#) Status on page 403
- [31.6.5 OFFERED\\_DEADLINE\\_MISSED](#) Status on page 404
- [31.6.6 OFFERED\\_INCOMPATIBLE\\_QOS](#) Status on page 404
- [31.6.7 PUBLICATION\\_MATCHED](#) Status on page 405
- [31.6.8 RELIABLE\\_WRITER\\_CACHE\\_CHANGED](#) Status (DDS Extension) on page 406
- [31.6.9 RELIABLE\\_READER\\_ACTIVITY\\_CHANGED](#) Status (DDS Extension) on page 408
- [31.6.10 SERVICE\\_REQUEST\\_ACCEPTED](#) Status (DDS Extension) on page 408

## 31.6.1 APPLICATION\_ACKNOWLEDGMENT\_STATUS

This status indicates that a *DataWriter* has received an application-level acknowledgment for a DDS sample, and triggers a *DataWriter* callback:

```
void DDSDataWriterListener::on_application_acknowledgment(
    DDSDataWriter * writer,
    const DDS_AcknowledgmentInfo & info)
```

**on\_application\_acknowledgment()** is called when a DDS sample is application-level acknowledged. It provides identities of the DDS sample and the acknowledging *DataReader*, as well as user-specified response data sent from the *DataReader* by the acknowledgment message—see [Table 31.4 DDS\\_AcknowledgmentInfo](#).

**Table 31.4 DDS\_AcknowledgmentInfo**

Type	Field Name	Description
DDS_InstanceHandle_t	subscription_handle	Subscription handle of the acknowledging <i>DataReader</i> .
struct DDS_SampleIdentity_t	sample_identity	Identity of the DDS sample being acknowledged.
DDS_Boolean	valid_response_data	Flag indicating validity of the user response data in the acknowledgment.
struct DDS_AckResponseData_t	response_data	User data payload of application-level acknowledgment message.

This status is only applicable when the *DataWriter*'s Reliability QoS Policy's **acknowledgment\_kind** is `DDS_APPLICATION_AUTO_ACKNOWLEDGMENT_MODE` or `DDS_APPLICATION_EXPLICIT_ACKNOWLEDGMENT_MODE`.

## 31.6.2 DATA\_WRITER\_CACHE\_STATUS

This status keeps track of the number of DDS samples and instances in the *DataWriter*'s queue. For information on instance states, see [19.1 Instance States on page 258](#).

This status does not have an associated *Listener*. You can access this status by calling the *DataWriter*'s `get_datawriter_cache_status()` operation, which will return the status structure described in [Table 31.5 DDS\\_DataWriterCacheStatus](#).

**Table 31.5 DDS\_DataWriterCacheStatus**

Type	Field Name	Description
DDS_Long	sample_count_peak	Highest number of DDS samples in the <i>DataWriter</i> 's queue over the lifetime of the <i>DataWriter</i> .
DDS_Long	sample_count	Current number of DDS samples in the <i>DataWriter</i> 's queue. This number includes meta-samples, which represent the unregistration or disposal of an instance.
DDS_LongLong	alive_instance_count	Number of instances currently in the <i>DataWriter</i> 's queue that have an <b>instance_state</b> of ALIVE.
DDS_LongLong	alive_instance_count_peak	Highest number of ALIVE instances in the <i>DataWriter</i> 's queue over the lifetime of the <i>DataWriter</i> .
DDS_LongLong	disposed_instance_count	Number of instances currently in the <i>DataWriter</i> 's queue that have an <b>instance_state</b> of NOT_ALIVE_DISPOSED.
DDS_LongLong	disposed_instance_count_peak	Highest number of NOT_ALIVE_DISPOSED instances in the <i>DataWriter</i> 's queue over the lifetime of the <i>DataWriter</i> .
DDS_LongLong	unregistered_instance_count	Number of instances currently in the <i>DataWriter</i> 's queue that the <i>DataWriter</i> has unregistered from via the <b>unregister_instance</b> operation.
DDS_LongLong	unregistered_instance_count_peak	Highest number of instances that the <i>DataWriter</i> has unregistered from, over the lifetime of the <i>DataWriter</i> .

### 31.6.3 DATA\_WRITER\_PROTOCOL\_STATUS

This status includes internal protocol related metrics (such as the number of DDS samples pushed, pulled, filtered) and the status of wire-protocol traffic.

- **Pulled DDS samples** are DDS samples sent for repairs (that is, DDS samples that had to be resent), for late joiners, and all DDS samples sent by the local *DataWriter* when **push\_on\_write** (in [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 788](#)) is `DDS_BOOLEAN_FALSE`.
- **Pushed DDS samples** are DDS samples sent on `write()` when **push\_on\_write** is `DDS_BOOLEAN_TRUE`.
- **Filtered DDS samples** are DDS samples that are not sent due to *DataWriter* filtering (time-based filtering and ContentFilteredTopics), but this field is not currently supported.
- **DATA\_FRAG messages** are fragments of samples if you are using DDS-level fragmentation. See [34.3 Large Data Fragmentation on page 524](#) for more information.

This status does not have an associated Listener. You can access this status by calling the following operations on the *DataWriter* (all of which return the status structure described in [Table 31.6 DDS\\_DataWriterProtocolStatus](#)):

- **get\_datawriter\_protocol\_status()** returns the sum of the protocol status for all the matched subscriptions for the *DataWriter*.
- **get\_matched\_subscription\_datawriter\_protocol\_status()** returns the protocol status of a particular matched subscription, identified by a `subscription_handle`.
- **get\_matched\_subscription\_datawriter\_protocol\_status\_by\_locator()** returns the protocol status of a particular matched subscription, identified by a locator. (See [24.1.1 Locator Format on page 327](#).)

**Note:** Status/data for a matched subscription is kept even if the *DataReader* is not active (has not responded to a heartbeat message with an ACK/NACK message after `max_heartbeat_retries` has been reached). The status/data will be removed only if the *DataReader* is gone: that is, the *DataReader* is destroyed and this change is propagated through a discovery update, or the *DataReader's DomainParticipant* is gone (either gracefully or its liveliness expired and *Connex* is configured to purge not-alive participants). Once a matched *DataReader* is gone, its status is deleted. If you try to get the status/data for a matched *DataReader* that is gone, the 'get status' or 'get data' call will return an error.

**Table 31.6 DDS\_DataWriterProtocolStatus**

Type	Field Name	Description
DDS_LongLong	<code>pushed_sample_count</code>	The number of user DDS samples pushed on write from this <i>DataWriter</i> to a matching <i>DataReader</i> . This field counts protocol (RTPS) messages pushed by a <i>DataWriter</i> when writing, unregistering, and disposing. The count is the number of sends done internally, and it may be greater than the number of user writes. This field counts whole samples, not fragments (in the case of large data). The fragment count is tracked in the <code>pushed_fragment_count</code> .
	<code>pushed_sample_count_change</code>	Change in the <code>pushed_sample_count</code> since the last time the status was read.
	<code>pushed_sample_bytes</code>	The number of bytes of user DDS samples pushed on write from this <i>DataWriter</i> to a matching <i>DataReader</i> . This field counts bytes of protocol (RTPS) messages pushed by a <i>DataWriter</i> when writing, unregistering, and disposing. The count of bytes corresponds to the number of sends done internally, and it may be greater than the number of user writes. When data fragmentation is used (for large data), this statistic is incremented as fragments are written.
	<code>pushed_sample_bytes_change</code>	Change in <code>pushed_sample_bytes</code> since the last time the status was read.

Table 31.6 DDS\_DataWriterProtocolStatus

Type	Field Name	Description
DDS_LongLong	<b>Not supported</b> filtered_sample_count	The number of user samples preemptively filtered by this <i>DataWriter</i> due to ContentFilteredTopics.
	<b>Not supported</b> filtered_sample_count_change	Change in the <b>filtered_sample_count</b> since the last time the status was read.
	<b>Not supported</b> filtered_sample_bytes	The number of bytes of user samples preemptively filtered by this <i>DataWriter</i> due to ContentFilteredTopics.
	<b>Not supported</b> filtered_sample_bytes_change	Change in the <b>filtered_sample_bytes</b> since the last time the status was read.
DDS_LongLong	sent_heartbeat_count	The number of Heartbeats sent between this <i>DataWriter</i> and matching <i>DataReaders</i> .
	sent_heartbeat_count_change	Change in the <b>sent_heartbeat_count</b> since the last time the status was read.
	sent_heartbeat_bytes	The number of bytes of Heartbeats sent between this <i>DataWriter</i> and matching <i>DataReaders</i> .
	sent_heartbeat_bytes_change	The incremental change in the number of bytes of Heartbeats sent between this <i>DataWriter</i> and matching <i>DataReaders</i> since the last time the status was read.
DDS_LongLong	pulled_sample_count	The number of user DDS samples pulled from this <i>DataWriter</i> by matching <i>DataReaders</i> . When data fragmentation is used, this statistic is incremented as fragments are written.
	pulled_sample_count_change	Change in the <b>pulled_sample_count</b> since the last time the status was read.
	pulled_sample_bytes	The number of bytes of user DDS samples pulled from this <i>DataWriter</i> by matching <i>DataReaders</i> . When data fragmentation is used, this statistic is incremented as fragments are written.
	pulled_sample_bytes_change	Change in <b>pulled_sample_bytes</b> since the last time the status was read.
DDS_LongLong	received_ack_count	The number of ACKs from a <i>DataReader</i> received by this <i>DataWriter</i> .
	received_ack_count_change	Change in the <b>received_ack_count</b> since the last time the status was read.
	received_ack_bytes	The number of bytes of ACKs from a <i>DataReader</i> received by this <i>DataWriter</i> .
	received_ack_bytes_change	Change in <b>received_ack_bytes</b> since the last time the status was read.

Table 31.6 DDS\_DataWriterProtocolStatus

Type	Field Name	Description
DDS_LongLong	received_nack_count	The number of NACKs from a <i>DataReader</i> received by this <i>DataWriter</i> .
	received_nack_count_change	Change in the <b>received_nack_count</b> since the last time the status was read.
	received_nack_bytes	The number of bytes of NACKs from a <i>DataReader</i> received by this <i>DataWriter</i> .
	received_nack_bytes_change	Change in the <b>received_nack_bytes</b> since the last time the status was read.
DDS_LongLong	sent_gap_count	The number of GAPS sent from this <i>DataWriter</i> to matching <i>DataReaders</i> .
	sent_gap_count_change	Change in the <b>sent_gap_count</b> since the last time the status was read.
	sent_gap_bytes	The number of bytes of GAPS sent from this <i>DataWriter</i> to matching <i>DataReaders</i> .
	sent_gap_bytes_change	Change in the <b>sent_gap_bytes</b> since the last time the status was read.
DDS_LongLong	<b>Not supported</b> rejected_sample_count	These fields are not supported.
	<b>Not supported</b> rejected_sample_count_change	
DDS_Long	send_window_size	Current size of the send window (maximum number of outstanding DDS samples allowed in the <i>DataWriter</i> 's queue), as determined by the <b>min/max_send_window_size</b> fields in <a href="#">Table 47.14 DDS_RtpsReliableWriterProtocol.t</a> . (See <a href="#">47.5.4 Configuring the Send Window Size on page 796</a> for information on how the send window size might change.)
DDS_LongLong	pushed_fragment_count	The number of fragments (DATA_FRAG messages) that have been pushed from this <i>DataWriter</i> to a <i>DataReader</i> . This count is incremented as each DATA_FRAG message is sent, not when the entire sample has been sent. Applicable only when data is fragmented.
	pushed_fragment_bytes	The number of bytes of DATA_FRAG messages that have been pushed by this <i>DataWriter</i> . This statistic is incremented as each DATA_FRAG message is sent, not when the entire sample has been sent. Applicable only when data is fragmented.
	pulled_fragment_count	The number of fragments (DATA_FRAG messages) that have been pulled from this <i>DataWriter</i> by a <i>DataReader</i> . This count is incremented as each DATA_FRAG message is sent, not when the entire sample has been sent. Applicable only when data is fragmented.
	pulled_fragment_bytes	The number of bytes of DATA_FRAG messages that have been pulled from this <i>DataWriter</i> by a <i>DataReader</i> . This statistic is incremented as each DATA_FRAG message is sent, not when the entire sample has been sent. Applicable only when data is fragmented.

Table 31.6 DDS\_DataWriterProtocolStatus

Type	Field Name	Description
DDS_LongLong	received_nack_fragment_count	The number of NACK_FRAG messages that have been received by this <i>DataWriter</i> . NACK FRAG RTPS messages are sent when large data is used in conjunction with reliable communication. They have the same properties as NACK messages, but instead of applying to samples, they apply to fragments. Applicable only when data is fragmented.
	received_nack_fragment_bytes	The number of bytes of NACK_FRAG messages that have been received by this <i>DataWriter</i> . NACK FRAG RTPS messages are sent when large data is used in conjunction with reliable communication. They have the same properties as NACK messages, but instead of applying to samples, they apply to fragments. Applicable only when data is fragmented.
DDS_SequenceNumber_t	first_available_sample_sequence_number	Sequence number of the first available DDS sample in the <i>DataWriter</i> 's reliability queue.
	last_available_sample_sequence_number	Sequence number of the last available DDS sample in the <i>DataWriter</i> 's reliability queue.
	first_unacknowledged_sample_sequence_number	Sequence number of the first unacknowledged DDS sample in the <i>DataWriter</i> 's reliability queue.
	first_available_sample_virtual_sequence_number	Virtual sequence number of the first available DDS sample in the <i>DataWriter</i> 's reliability queue.
	last_available_sample_virtual_sequence_number	Virtual sequence number of the last available DDS sample in the <i>DataWriter</i> 's reliability queue.
	first_unacknowledged_sample_virtual_sequence_number	Virtual sequence number of the first unacknowledged DDS sample in the <i>DataWriter</i> 's reliability queue.
DDS_SequenceNumber_t	first_unacknowledged_sample_subscription_handle	Instance Handle of the matching remote <i>DataReader</i> for which the <i>DataWriter</i> has kept the first available DDS sample in the reliability queue.
	first_unelapsed_keep_duration_sample_sequence_number	Sequence number of the first DDS sample kept in the <i>DataWriter</i> 's queue whose keep_duration (applied when <b>disable_positive_acks</b> is set) has not yet elapsed.

### 31.6.4 LIVELINESS\_LOST Status

A change to this status indicates that the *DataWriter* failed to signal its liveliness within the time specified by the [47.15 LIVELINESS QosPolicy on page 825](#).

It is different than the [31.6.9 RELIABLE\\_READER\\_ACTIVITY\\_CHANGED Status \(DDS Extension\) on page 408](#) status that provides information about the liveliness of a *DataWriter*'s matched *DataReaders*; this status reflects the *DataWriter*'s own liveliness.

The structure for this status appears in [Table 31.7 DDS\\_LivelinessLostStatus](#).

**Table 31.7 DDS\_LivelinessLostStatus**

Type	Field Name	Description
DDS_Long	total_count	Cumulative number of times the <i>DataWriter</i> failed to explicitly signal its liveliness within the liveliness period.
DDS_Long	total_count_change	The change in total_count since the last time the Listener was called or the status was read.

The *DataWriterListener*'s **on\_liveliness\_lost()** callback is invoked when this status changes. You can also retrieve the value by calling the *DataWriter*'s **get\_liveliness\_lost\_status()** operation.

### 31.6.5 OFFERED\_DEADLINE\_MISSED Status

A change to this status indicates that the *DataWriter* failed to write data within the time period set in its [47.7 DEADLINE QoS Policy on page 804](#).

The structure for this status appears in [Table 31.8 DDS\\_OfferedDeadlineMissedStatus](#).

**Table 31.8 DDS\_OfferedDeadlineMissedStatus**

Type	Field Name	Description
DDS_Long	total_count	Cumulative number of times the <i>DataWriter</i> failed to write within its offered deadline.
DDS_Long	total_count_change	The change in total_count since the last time the <i>Listener</i> was called or the status was read.
DDS_InstanceHandle_t	last_instance_handle	Handle to the last data-instance in the <i>DataWriter</i> for which an offered deadline was missed.

The *DataWriterListener*'s **on\_offered\_deadline\_missed()** operation is invoked when this status changes. You can also retrieve the value by calling the *DataWriter*'s **get\_deadline\_missed\_status()** operation.

### 31.6.6 OFFERED\_INCOMPATIBLE\_QOS Status

A change to this status indicates that the *DataWriter* discovered a *DataReader* for the same *Topic*, but that *DataReader* had requested QoS settings incompatible with this *DataWriter*'s offered QoS.

The structure for this status appears in [Table 31.9 DDS\\_OfferedIncompatibleQoSStatus](#).

Table 31.9 DDS\_OfferedIncompatibleQoSStatus

Type	Field Name	Description
DDS_Long	total_count	Cumulative number of times the <i>DataWriter</i> discovered a <i>DataReader</i> for the same <i>Topic</i> with a requested QoS that is incompatible with that offered by the <i>DataWriter</i> .
DDS_Long	total_count_change	The change in total_count since the last time the <i>Listener</i> was called or the status was read.
DDS_QoSPolicyId_t	last_policy_id	The ID of the QoSPolicy that was found to be incompatible the last time an incompatibility was detected. (Note: if there are multiple incompatible policies, only one of them is reported here.)
DDS_QoSPolicyCountSeq	policies	A list containing—for each policy—the total number of times that the <i>DataWriter</i> discovered a <i>DataReader</i> for the same <i>Topic</i> with a requested QoS that is incompatible with that offered by the <i>DataWriter</i> .

The *DataWriterListener*'s **on\_offered\_incompatible\_qos()** callback is invoked when this status changes. You can also retrieve the value by calling the *DataWriter*'s **get\_offered\_incompatible\_qos\_status()** operation.

### 31.6.7 PUBLICATION\_MATCHED Status

A change to this status indicates that the *DataWriter* discovered a matching *DataReader*.

A 'match' occurs only if the *DataReader* and *DataWriter* have the same *Topic*, same or compatible data type, and compatible QoS Policies. (For more information on compatible data types, see the [RTI Connex Core Libraries Extensible Types Guide](#).) In addition, if user code has directed *Connex* to ignore certain *DataReaders*, then those *DataReaders* will never be matched. See [27.2 Ignoring Publications and Subscriptions on page 354](#) for more on setting up a *DomainParticipant* to ignore specific *DataReaders*.

This status is also changed (and the listener, if any, called) when a match is ended. A local *DataWriter* will become "unmatched" from a remote *DataReader* when that *DataReader* goes away for any of the following reasons:

- The matched *DataReader*'s *DomainParticipant* has lost liveliness.
- This *DataWriter* or the matched *DataReader* has changed QoS such that the entities are now incompatible.
- The matched *DataReader* has been deleted.

This status may reflect changes from multiple match or unmatched events, and the **current\_count\_change** can be used to determine the number of changes since the listener was called back or the status was checked.

The structure for this status appears in [Table 31.10 DDS\\_PublicationMatchedStatus](#).

Table 31.10 DDS\_PublicationMatchedStatus

Type	Field Name	Description
DDS_Long	total_count	Cumulative number of times that this <i>DataWriter</i> discovered a "match" with a <i>DataReader</i> . This number increases whenever a new match is discovered. It does not decrease when an existing match goes away for any of the reasons listed above.
	total_count_change	The changes in <b>total_count</b> since the last time the listener was called or the status was read. Note that this number will never be negative (because it's the total number of times the <i>DataWriter</i> ever matched with a <i>DataReader</i> ).
	current_count	The number of <i>DataReaders</i> currently matched to the <i>DataWriter</i> . This number increases when a new match is discovered and decreases when an existing match goes away for any of the reasons listed above.
	current_count_peak	Greatest number of <i>DataReaders</i> that matched this <i>DataWriter</i> simultaneously. That is, there was no moment in time when more than this many <i>DataReaders</i> matched this <i>DataWriter</i> . (As a result, <b>total_count</b> can be higher than <b>current_count_peak</b> .)
	current_count_change	The change in <b>current_count</b> since the last time the listener was called or the status was read. Note that a negative <b>current_count_change</b> means that one or more <i>DataReaders</i> have become unmatched for one or more of the reasons listed above.
DDS_InstanceHandle_t	last_subscription_handle	This InstanceHandle can be used to look up which remote <i>DataReader</i> was the last to cause this <i>DataWriter</i> 's status to change, using the <i>DataWriter</i> 's <b>get_matched_subscription_data()</b> method.  If the <i>DataReader</i> no longer matches this <i>DataWriter</i> due to any of the reasons listed above except incompatible QoS, then the <i>DataReader</i> has been purged from this <i>DataWriter</i> 's <i>DomainParticipant</i> discovery database. (See <a href="#">Chapter 22 Discovery Overview on page 309</a> .) In that case, the <i>DataWriter</i> 's <b>get_matched_subscription_data()</b> method will not be able to return information about the <i>DataReader</i> . The only way to get information about the lost <i>DataReader</i> is if you cached the information previously.

The *DataWriterListener*'s **on\_publication\_matched()** callback is invoked when this status changes. You can also retrieve the value by calling the *DataWriter*'s **get\_publication\_match\_status()** operation.

### 31.6.8 RELIABLE\_WRITER\_CACHE\_CHANGED Status (DDS Extension)

A change to this status indicates that the number of unacknowledged DDS samples<sup>1</sup> in a reliable *DataWriter*'s cache has reached one of these trigger points:

- The cache is empty (contains no unacknowledged DDS samples)
- The cache is full (the number of unacknowledged DDS samples has reached the value specified in **DDS\_ResourceLimitsQosPolicy::max\_samples**)
- The number of unacknowledged DDS samples has reached a high or low watermark. See the **high\_watermark** and **low\_watermark** fields in [Table 47.14 DDS\\_RtpsReliableWriterProtocol\\_t](#) of the [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\)](#) on page 788.

<sup>1</sup>If batching is enabled, this still refers to a number of *DDS samples*, not *batches*.

For more about the reliable protocol used by *Connex* and specifically, what it means for a DDS sample to be ‘unacknowledged,’ see [Reliability Models for Sending Data \(Chapter 32 on page 446\)](#).

The structure for this status appears in [Table 31.11 DDS\\_ReliableWriterCacheChangedStatus](#). The supporting structure, [DDS\\_ReliableWriterCacheEventCount](#), is described in [Table 31.12 DDS\\_ReliableWriterCacheEventCount](#).

**Table 31.11 DDS\_ReliableWriterCacheChangedStatus**

Type	Field Name	Description
DDS_ReliableWriterCacheEventCount	empty_reliable_writer_cache	How many times the reliable <i>DataWriter's</i> cache of unacknowledged DDS samples has become empty.
	full_reliable_writer_cache	How many times the reliable <i>DataWriter's</i> cache of unacknowledged DDS samples has become full.
	low_watermark_reliable_writer_cache	How many times the reliable <i>DataWriter's</i> cache of unacknowledged DDS samples has fallen to the low watermark.
	high_watermark_reliable_writer_cache	How many times the reliable <i>DataWriter's</i> cache of unacknowledged DDS samples has risen to the high watermark.
DDS_Long	unacknowledged_sample_count	The current number of unacknowledged DDS samples in the <i>DataWriter's</i> cache.
	unacknowledged_sample_count_peak	The highest value that <b>unacknowledged_sample_count</b> has reached until now.
DDS_LongLong	replaced_unacknowledged_sample_count	Total number of unacknowledged samples that have been replaced by a <i>DataWriter</i> after applying the KEEP_LAST setting in the <a href="#">47.12 HISTORY QosPolicy on page 818</a> policy.

**Table 31.12 DDS\_ReliableWriterCacheEventCount**

Type	Field Name	Description
DDS_Long	total_count	The total number of times the event has occurred.
DDS_Long	total_count_change	The number of times the event has occurred since the <i>Listener</i> was last invoked or the status read.

The *DataWriterListener's* **on\_reliable\_writer\_cache\_changed()** callback is invoked when this status changes. You can also retrieve the value by calling the *DataWriter's* **get\_reliable\_writer\_cache\_changed\_status()** operation.

If a reliable *DataWriter's* send window is finite, with both **RtpsReliableWriterProtocol\_t.min\_send\_window\_size** and **RtpsReliableWriterProtocol\_t.max\_send\_window\_size** set to positive values, then **full\_reliable\_writer\_cache\_status** counts the number of times the unacknowledged DDS sample count reaches the send window size.

## 31.6.9 RELIABLE\_READER\_ACTIVITY\_CHANGED Status (DDS Extension)

This status indicates that one or more reliable *DataReaders* has become active or inactive.

This status is the reciprocal status to the [40.7.4 LIVELINESS\\_CHANGED Status on page 634](#) on the *DataReader*. It is different than [31.6.4 LIVELINESS\\_LOST Status on page 403](#) status on the *DataWriter*, in that the latter informs the *DataWriter* about its *own* liveliness; this status informs the *DataWriter* about the liveliness of its matched *DataReaders*.

A reliable *DataReader* is considered active by a reliable *DataWriter* with which it is matched if that *DataReader* acknowledges the DDS samples that it has been sent in a timely fashion. For the definition of "timely" in this context, see [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 788](#).

This status is only used for *DataWriters* whose [47.21 RELIABILITY QosPolicy on page 845](#) is set to RELIABLE. For best-effort *DataWriters*, all counts in this status will remain at zero.

The structure for this status appears in [Table 31.13 DDS\\_ReliableReaderActivityChangedStatus](#).

**Table 31.13 DDS\_ReliableReaderActivityChangedStatus**

Type	Field Name	Description
DDS_Long	active_count	The current number of reliable readers currently matched with this reliable <i>DataWriter</i> .
	inactive_count	The number of reliable readers that have been dropped by this reliable <i>DataWriter</i> because they failed to send acknowledgments in a timely fashion.
	active_count_change	The change in the number of active reliable <i>DataReaders</i> since the <i>Listener</i> was last invoked or the status read.
	inactive_count_change	The change in the number of inactive reliable <i>DataReaders</i> since the <i>Listener</i> was last invoked or the status read.
DDS_InstanceHandle_t	last_instance_handle	The instance handle of the last reliable <i>DataReader</i> to be determined to be inactive.

The *DataWriterListener*'s **on\_reliable\_reader\_activity\_changed()** callback is invoked when this status changes. You can also retrieve the value by calling the *DataWriter*'s **get\_reliable\_reader\_activity\_changed\_status()** operation.

## 31.6.10 SERVICE\_REQUEST\_ACCEPTED Status (DDS Extension)

A change to this status indicates that ServiceRequest for the TopicQuery service is dispatched to this *DataWriter* for processing. For more information, see [Topic Queries \(Chapter 60 on page 1142\)](#).

The structure for this status appears in [Table 31.14 DDS\\_ServiceRequestAcceptedStatus](#).

The *DataWriterListener*'s **on\_service\_request\_accepted()** callback is invoked when this status changes.

You can also retrieve the value by calling the *DataWriter's* `get_service_request_accepted_status()` operation.

**Table 31.14 DDS\_ServiceRequestAcceptedStatus**

Type	Field Name	Description
DDS_Long	total_count	The total cumulative number of ServiceRequests that have been accepted by a <i>DataWriter</i> .
	total_count_change	The incremental changes in total_count since the last time the listener was called or the status was read.
	current_count	The current number of ServiceRequests that have been accepted by this <i>DataWriter</i> .
	current_count_change	The change in current_count since the last time the listener was called or the status was read.
DDS_InstanceHandle_t	last_request_handle	A handle to the last DDS_ServiceRequest that caused the <i>DataWriter's</i> status to change.
DDS_Long	service_id	ID of the service to which the accepted Request belongs

## 31.7 Using a Type-Specific DataWriter (FooDataWriter)

(Note: This section does not apply to the Modern C++ API, where a *DataWriter's* data type is part of its template definition: **DataWriter<Foo>**)

Recall that a *Topic* is bound to a data type that specifies the format of the data associated with the *Topic*. Data types are either defined dynamically or in code generated from definitions in IDL or XML; see [Data Types and DDS Data Samples \(Chapter 17 on page 110\)](#). For each of your application's generated data types, such as 'Foo', there will be a *FooDataWriter* class (or a set of functions in C). This class allows the application to use a type-safe interface to interact with DDS samples of type 'Foo'. You will use the *FooDataWriter's* `write()` operation used to send data. For dynamically defined data-types, you will use the *DynamicDataWriter* class.

In fact, you will use the *FooDataWriter* any time you need to perform type-specific operations, such as registering or writing instances. [Table 31.1 DataWriter Operations](#) indicates which operations must be called using *FooDataWriter*. For operations that are not type-specific, you can call the operation using either a *FooDataWriter* or a *DDSDataWriter* object<sup>1</sup>.

You may notice that the *Publisher's* `create_datawriter()` operation returns a pointer to an object of type **DDSDataWriter**; this is because the `create_datawriter()` method is used to create *DataWriters* of any data type. However, when executed, the function actually returns a specialization (an object of a derived class) of the *DataWriter* that is specific for the data type of the associated *Topic*. For a *Topic* of type 'Foo', the object actually returned by `create_datawriter()` is a **FooDataWriter**.

<sup>1</sup>In the C API, the non type-specific operations must be called using a *DDS\_DataWriter* pointer.

To safely cast a generic **DDSDataWriter** pointer to a **FooDataWriter** pointer, you should use the static **narrow()** method of the **FooDataWriter** class. The **narrow()** method will return **NULL** if the generic **DDSDataWriter** pointer is not pointing at an object that is really a **FooDataWriter**.

For instance, if you create a *Topic* bound to the type ‘**Alarm**’, all *DataWriters* created for that *Topic* will be of type ‘**AlarmDataWriter**.’ To access the type-specific methods of **AlarmDataWriter**, you must cast the generic **DDSDataWriter** pointer returned by **create\_datawriter()**. For example:

```
DDSDataWriter* writer = publisher->create_datawriter(
    topic,writer_qos, NULL, NULL);
AlarmDataWriter *alarm_writer = AlarmDataWriter::narrow(writer);
if (alarm_writer == NULL) {
    // ... error
};
```

In the C API, there is also a way to do the opposite of **narrow()**. **FooDataWriter\_as\_datawriter()** casts a **FooDataWriter** as a **DDSDataWriter**, and **FooDataReader\_as\_datareader()** casts a **FooDataReader** as a **DDSDataReader**.

## 31.8 Writing Data

The **write()** operation informs *Connex* that there is a new value for a data-instance to be published for the corresponding *Topic*. By default, calling **write()** will send the data immediately over the network (assuming that there are matched *DataReaders*). However, you can configure and execute operations on the *DataWriter*’s *Publisher* to buffer the data so that it is sent in a batch with data from other *DataWriters* or even to prevent the data from being sent. Those sending “modes” are configured using the [46.6 PRESENTATION QosPolicy on page 760](#) as well as the *Publisher*’s **suspend/resume\_publications()** operations. The actual transport-level communications may be done by a separate, lower-priority thread when the *Publisher* is configured to send the data for its *DataWriters*. For more information on threads, see [Part 11: Connex Threading Model \(on page 1180\)](#).

When you call **write()**, *Connex* automatically attaches a stamp of the current time that is sent with the DDS data sample to the *DataReader*(s). The timestamp appears in the **source\_timestamp** field of the **DDS\_SampleInfo** structure that is provided along with your data using *DataReaders* (see [41.6 The SampleInfo Structure on page 676](#)).

```
DDS_ReturnCode_t write (const Foo &instance_data,
    const DDS_InstanceHandle_t &handle)
```

You can use an alternate *DataWriter* operation called **write\_w\_timestamp()**. This performs the same action as **write()**, but allows the application to explicitly set the **source\_timestamp**. This is useful when you want the user application to set the value of the timestamp instead of the default clock used by *Connex*.

```
DDS_ReturnCode_t write_w_timestamp (
    const Foo &instance_data,
    const DDS_InstanceHandle_t &handle,
    const DDS_Time_t &source_timestamp)
```

Note that, in general, the application should not mix these two ways of specifying timestamps. That is, for each *DataWriter*, the application should either always use the automatic timestamping mechanism (by calling the normal operations) or always specify a timestamp (by calling the “**w\_timestamp**” variants of the operations). Mixing the two methods may result in not receiving sent data.

You can also use an alternate *DataWriter* operation, **write\_w\_params()**, which performs the same action as **write()**, but allows the application to explicitly set the fields contained in the **DDS\_WriteParams** structure, see [Table 31.15 DDS\\_WriteParams\\_t](#).

**Table 31.15 DDS\_WriteParams\_t**

Type	Field Name	Description
DDS_Boolean	replace_auto	Allows retrieving the actual value of those fields that were automatic. When this field is set to true, the fields that were configured with an automatic value (for example, DDS_AUTO_SAMPLE_IDENTITY in identity) receive their actual value after write_w_params is called.
DDS_SampleIdentity_t	identity	Identity of the DDS sample being written. The identity consists of a pair (Virtual Writer GUID, Virtual Sequence Number). When the value DDS_AUTO_SAMPLE_IDENTITY is used, the <b>write_w_params()</b> operation will determine the DDS sample identity as follows: <ul style="list-style-type: none"> <li>The Virtual Writer GUID (<b>writer_guid</b>) is the virtual GUID associated with the <i>DataWriter</i> writing the DDS sample. This virtual GUID is configured using the member <b>virtual_guid</b> in <a href="#">47.5 DATA_WRITER_PROTOCOL QosPolicy (DDS Extension)</a> on page 788.</li> <li>The Virtual Sequence Number (<b>sequence_number</b>) is increased by one with respect to the previous value.</li> </ul> <p>The virtual sequence numbers for a given virtual GUID must be strictly monotonically increasing. If you try to write a DDS sample with a sequence number smaller or equal to the last sequence number, the write operation will fail.</p> <p>A <i>DataReader</i> can inspect the identity of a received DDS sample by accessing the fields <b>original_publication_virtual_guid</b> and <b>original_publication_virtual_sequence_number</b> in <a href="#">41.6 The SampleInfo Structure</a> on page 676.</p>
DDS_SampleIdentity_t	related_sample_identity	The identity of another DDS sample related to this one. The value of this field identifies another DDS sample that is logically related to the one that is written. For example, the <i>DataWriter</i> created by a Replier (sets <a href="#">Introduction to the Request-Reply Communication Pattern (61.1 on page 1146)</a> ) uses this field to associate the identity of the DDS request sample to reponse sample. To specify that there is no related DDS sample identity use the value DDS_UNKNOWN_SAMPLE_IDENTITY, A <i>DataReader</i> can inspect the related DDS sample identity of a received DDS sample by accessing the fields <b>related_original_publication_virtual_guid</b> and <b>related_original_publication_virtual_sequence_number</b> in <a href="#">41.6 The SampleInfo Structure</a> on page 676.
DDS_Time	source_timestamp	Source timestamp that will be associated to the DDS sample that is written. If source_timestamp is set to DDS_TIMER_INVALID, the middleware will assign the value. A <i>DataReader</i> can inspect the source_timestamp value of a received DDS sample by accessing the field <b>source_timestamp</b> <a href="#">41.6 The SampleInfo Structure</a> on page 676.
DDS_InstanceHandle_t	handle	The instance handle. This value can be either the handle returned by a previous call to <b>register_instance()</b> or the special value DDS_HANDLE_NIL.

Table 31.15 DDS\_WriteParams\_t

Type	Field Name	Description
DDS_Long	priority	<p>Positive integer designating the relative priority of the DDS sample, used to determine the transmission order of pending transmissions.</p> <p>To use publication priorities, the <i>DataWriter's</i> <a href="#">47.20 PUBLISH_MODE QosPolicy (DDS Extension) on page 843</a> must be set for asynchronous publishing and the <i>DataWriter</i> must use a <i>FlowController</i> with a highest-priority first scheduling_policy.</p> <p>For Multi-channel <i>DataWriters</i>, the publication priority of a DDS sample may be used as a filter criteria for determining channel membership.</p> <p>For more information, see <a href="#">34.4.4 Prioritized DDS Samples on page 538</a>.</p>
DDS_Long	flag	<p>Flags for the DDS sample, represented as a 32-bit integer, of which only the 16 least-significant bits are used. RTI reserves least-significant bits [0-7] for middleware-specific usage. The application can use least significant bits [8-15].</p> <p>An application can inspect the flags associated with a received DDS sample by checking the <b>flag</b> field in <a href="#">41.6 The SampleInfo Structure on page 676</a>.</p> <p>For details about the reserved bits see <a href="#">41.6 The SampleInfo Structure on page 676</a>.</p> <p>Default 0 (no flags are set).</p>
struct DDS_GUID_t	source_guid	Identifies the application logical data source associated with the sample being written.
struct DDS_GUID_t	related_source_guid	Identifies the application logical data source that is related to the sample being written.
struct DDS_GUID_t	related_reader_guid	Identifies a <i>DataReader</i> that is logically related to the sample that is being written.

When using the C API, a newly created variable of type `DDS_WriteParams_t` should be initialized by setting it to `DDS_WRITEPARAMS_DEFAULT`.

The `write()` operation also asserts liveness on the *DataWriter*, the associated *Publisher*, and the associated *DomainParticipant*. It has the same effect with regards to liveness as an explicit call to `assert_liveliness()`, see [31.17 Asserting Liveness on page 444](#) and the [47.15 LIVELINESS QosPolicy on page 825](#). Maintaining liveness is important for *DataReaders* to know that the *DataWriter* still exists and for the proper behavior of the [47.17 OWNERSHIP QosPolicy on page 833](#).

See also: [16.3.15 Configuring the Clock per DomainParticipant on page 105](#).

### 31.8.1 Blocking During a write()

The `write()` operation may block if the [47.21 RELIABILITY QosPolicy on page 845](#) *kind* is set to *Reliable*, the send window is full, or the modification would cause data to be lost. Specifically, `write()` may block in the following situations (note that the list may not be exhaustive):

- If the send window is specified (`max/min_send_window_size` fields in the `DDS_RtpsReliableWriterProtocol_t` structure in the [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS](#)

[Extension](#)) on page 788 are not LENGTH\_UNLIMITED) and the send window is full. Blocking in this case occurs with both KEEP\_LAST and KEEP\_ALL history **kinds**.

- If **max\_samples** or **max\_samples\_per\_instance** in the [47.22 RESOURCE\\_LIMITS QoSPolicy on page 850](#) (or **max\_batches** in [47.6 DATA\\_WRITER\\_RESOURCE\\_LIMITS QoSPolicy \(DDS Extension\) on page 800](#)) are exceeded and none of the samples can be replaced because they are not fully ACKed. Blocking in this case only applies to the KEEP\_ALL history **kind**.

This operation may also block when using BEST\_EFFORT Reliability [47.21 RELIABILITY QoSPolicy on page 845](#)) and ASYNCHRONOUS Publish Mode ([47.20 PUBLISH\\_MODE QoSPolicy \(DDS Extension\) on page 843](#)) QoS settings. In this case, the *DataWriter* will queue DDS samples until they are sent by the asynchronous publishing thread. The number of DDS samples that can be stored is determined by the [47.12 HISTORY QoSPolicy on page 818](#). If the asynchronous thread does not send DDS samples fast enough (such as when using a slow FlowController ([34.4 FlowControllers \(DDS Extension\) on page 532](#))), the queue may fill up. In that case, subsequent write calls will block.

If this operation does block for any of the above reasons, the [47.21 RELIABILITY QoSPolicy on page 845](#)'s **max\_blocking\_time** configures the maximum time the write operation may block (waiting for space to become available). If **max\_blocking\_time** elapses before the *DataWriter* can store the modification without exceeding the limits, the operation will fail and return **RETCODE\_TIMEOUT** for KEEP\_ALL configurations.

## 31.8.2 write() behavior with KEEP\_LAST and KEEP\_ALL

Following is how the write operation behaves when KEEP\_LAST (in the [47.12 HISTORY QoSPolicy on page 818](#)) and RELIABLE (in the [47.21 RELIABILITY QoSPolicy on page 845](#)) are used:

- The send window size is determined by the **max/min\_send\_window\_size** fields in the `DDS_RtpsReliableWriterProtocol_t` structure in the [47.5 DATA\\_WRITER\\_PROTOCOL QoSPolicy \(DDS Extension\) on page 788](#). If a send window is specified (**max\_send\_window\_size** is not UNLIMITED) and the window is full, the write operation will block until one of the samples in the send window is protocol-acknowledged (ACKed) ([Note 1](#)) or until the **max\_blocking\_time** in the [47.21 RELIABILITY QoSPolicy on page 845](#) (**writer\_qos.reliability.max\_blocking\_time**) expires.
- Then, the *DataWriter* will try to add the new sample to the writer history.
- If the instance associated with the sample is present in the writer history and there are **depth** (in the [47.12 HISTORY QoSPolicy on page 818](#)) samples in the instance, the *DataWriter* will replace the oldest sample of that instance independently of that sample's acknowledged status, and the write operation will return `DDS_RETCODE_OK`. Otherwise, no sample will be replaced and the write operation will continue.
- If the instance associated with the sample is not present in the writer history and **max\_instances** (in the [47.22 RESOURCE\\_LIMITS QoSPolicy on page 850](#)) is exceeded, the *DataWriter* will try

to replace an existing instance (and its samples) according to the value of the **instance\_replacement** field in the [47.6 DATA\\_WRITER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 800](#) (see [47.6.1 Configuring DataWriter Instance Replacement on page 802](#)).

- If no instance can be replaced, the write operation returns a `DDS_RETCODE_OUT_OF_RESOURCES` error.
- If **max\_samples** (in the [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#)) is exceeded, the *DataWriter* will try to drop a sample from a different instance as follows:
  - The *DataWriter* will try first to remove a fully ACKed ([Note 2](#)) sample from a different instance 'I' as long as that sample is not the last remaining sample for the instance 'I'. To find this sample, the *DataWriter* starts iterating from the oldest sample in the writer history to the newest sample.
  - If no such sample is found, the *DataWriter* will replace the oldest sample in the writer history.
- The sample is added to the writer history, and the write operation returns `DDS_RETCODE_OK`.

Following is how the write operation behaves when `KEEP_ALL` (in the [47.12 HISTORY QosPolicy on page 818](#)) and `RELIABLE` (in the [47.21 RELIABILITY QosPolicy on page 845](#)) are used:

- The send window size is determined by the **max/min\_send\_window\_size** fields in the `DDS_RtpsReliableWriterProtocol_t` structure in the [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 788](#). If a send window is specified (**max\_send\_window\_size** is not `UNLIMITED`) and the window is full, the write operation will block until one of the samples in the send window is protocol-ACKed ([Note 1](#)) or until the **max\_blocking\_time** in the [47.21 RELIABILITY QosPolicy on page 845](#) (**writer\_qos.reliability.max\_blocking\_time**) expires.
  - If **writer\_qos.reliability.max\_blocking\_time** expires, the write operation returns `DDS_RETCODE_TIMEOUT`.
- When a sample is protocol-ACKed ([Note 1](#)) before **max\_blocking\_time** expires, the *DataWriter* will try to add the sample to the writer history as follows:
  - If the instance associated with the sample is not present in the writer history and **max\_instances** is exceeded, the *DataWriter* will try to replace an existing instance (and its samples) according to the value of the **instance\_replacement** field in the [47.6 DATA\\_WRITER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 800](#) (see [47.6.1 Configuring DataWriter Instance Replacement on page 802](#)).
    - If no instance can be replaced, the write operation returns a `DDS_RETCODE_OUT_OF_RESOURCES` error.
  - If **max\_samples** is exceeded, the *DataWriter* will go through the samples in the order in which they were added, and it will replace the first sample that is fully ACKed ([Note 2](#)).

- If no fully ACKed sample is found, the *DataWriter* will block (Note 3) until a sample is fully ACKed and can be replaced or **writer\_qos.reliability.max\_blocking\_time** expires. If **writer\_qos.reliability.max\_blocking\_time** expires, the write operation will return DDS\_RETCODE\_TIMEOUT.
- If **max\_samples\_per\_instance** is exceeded, the *DataWriter* will go through the samples of the instance in the order in which they were added, and it will replace the first sample that is fully ACKed.
  - If no fully ACKed sample is found, the *DataWriter* will block (Note 3) until a sample is fully ACKed and can be replaced or **writer\_qos.reliability.max\_blocking\_time** expires. If **writer\_qos.reliability.max\_blocking\_time** expires, the write operation will return DDS\_RETCODE\_TIMEOUT.
- The sample is added to the writer history, and the write operation returns DDS\_RETCODE\_OK.

See [31.12.1 Application Acknowledgment Kinds on page 418](#) for more information on the following notes:

**Note 1:** A sample in the writer history is considered “protocol ACKed” when the sample has been individually ACKed at the RTPS protocol level by each one of the *DataReaders* that matched the *DataWriter* at the moment the sample was added to the *DataWriter* queue.

- Late joiners do not change the protocol ACK state of a sample. If a sample is marked as protocol ACKed because it has been acknowledged by all the matching *DataReaders* and a *DataReader* joins later on, the historical sample is still considered protocol ACKed even if it has not been received by the late joiner.
- If a sample 'S1' is protocol ACKed and a TopicQuery is received, triggering the publication of 'S1', the sample is still considered protocol ACKed. If a sample 'S1' is not ACKed and a TopicQuery is received triggering the publication of 'S1', the *DataWriter* will require that both the matching *DataReaders* on the live RTPS channel and the *DataReader* on the TopicQuery channel individually protocol ACK the sample in order to consider the sample protocol ACKed.

**Note 2:** A sample in the writer history is considered “fully ACKed” when all of the following conditions are met:

- The sample is protocol-ACKed.
- The sample has been “application-level ACKed” by all the *DataReaders* matching the *DataWriter* that have their **reader\_qos.reliability.acknowledgment\_kind** set to **AUTO\_ACKNOWLEDGMENT\_MODE** or **EXPLICIT\_ACKNOWLEDGMENT\_MODE**. Once the sample is application-level ACKed, it

cannot change its status to not ACKed after new *DataReaders* are matched. (Application-level ACK occurs when the application acknowledges receipt of a sample.)

- If required subscriptions are enabled (see [47.1 AVAILABILITY QoSPolicy \(DDS Extension\) on page 769](#)), the sample must also be ACKed by all the required subscriptions configured on the *DataWriter*.

**Note 3:** It is possible within a single call to the write operation for a *DataWriter* to block both when the send window is full and then again when **max\_samples** or **max\_samples\_per\_instance** is exceeded. This can happen because blocking on the send window only considers protocol-ACKed samples, while blocking based on resource limits considers fully-ACKed samples. In any case, the total max blocking time of a single call to the write operation will not exceed **writer\_qos.reliability.max\_blocking\_time**.

The write operation on a *DataWriter* configured to use batching may also block if the sample being written cannot be added to the existing outstanding batch and the batch has to be synchronously flushed within the context of the write thread (see [47.2.1 Synchronous and Asynchronous Flushing on page 775](#)). The flushing operation may block under the same scenarios described above for individual samples, taking into account that the send window is applied per batch and not per sample.

The **unregister\_instance()** and **dispose()** operations, with regards to KEEP\_LAST and KEEP\_ALL, behave the same as for the **write()** operation. See [31.14.2 Registering Instances on page 426](#), [31.14.4 Unregistering Instances on page 429](#), and [31.14.3 Disposing Instances on page 428](#).

## 31.9 Flushing Batches of DDS Data Samples

The **flush()** operation makes a batch of DDS data samples available to be sent on the network.

```
DDS_ReturnCode_t flush ()
```

If the *DataWriter*'s [47.20 PUBLISH\\_MODE QoSPolicy \(DDS Extension\) on page 843](#) **kind** is **not** ASYNCHRONOUS, the batch will be sent on the network immediately in the context of the calling thread.

If the *DataWriter*'s PublishModeQoSPolicy **kind** is ASYNCHRONOUS, the batch will be sent in the context of the asynchronous publishing thread.

The **flush()** operation may block based on the conditions described in [31.8.1 Blocking During a write\(\) on page 412](#).

If this operation does block, the **max\_blocking\_time** in the [47.21 RELIABILITY QoSPolicy on page 845](#) configures the maximum time the write operation may block (waiting for space to become available). If **max\_blocking\_time** elapses before the *DataWriter* is able to store the modification without exceeding the limits, the operation will fail and return TIMEOUT.

For more information on batching, see the [47.2 BATCH QoSPolicy \(DDS Extension\) on page 773](#).

## 31.10 Writing Coherent Sets of DDS Data Samples

A publishing application can request that a set of DDS data-sample changes be propagated in such a way that they are interpreted at the receivers' side as a cohesive set of modifications. In this case, the receiver will only be able to access the data after all the modifications in the set are available at the subscribing end.

This is useful in cases where the values are inter-related. For example, suppose you have two data-instances representing the ‘altitude’ and ‘velocity vector’ of the same aircraft. If both are changed, it may be important to ensure that reader see both together (otherwise, it may erroneously interpret that the aircraft is on a collision course).

To use this mechanism in C, Traditional C++, Java and .NET:

1. Call the *Publisher's* **begin\_coherent\_changes()** operation to indicate the start a coherent set.
2. For each DDS sample in the coherent set: call the *FooDataWriter's* **write()** operation.
3. Call the *Publisher's* **end\_coherent\_changes()** operation to terminate the set.

In the Modern C++ API:

1. Instantiate a **dds::pub::CoherentSet** passing a publisher to the constructor
2. For each DDS sample in the coherent set call **dds::pub::DataWriter<Foo>::write()**.
3. Let the **dds::pub::CoherentSet** destructor terminate the set or explicitly call **dds::pub::CoherentSet::end()**

Calls to **begin\_coherent\_changes()** and **end\_coherent\_changes()** can be nested. *Publisher's* samples (samples published by any of the *DataWriters* within the *Publisher*) that are not published within a **begin\_coherent\_changes/end\_coherent\_changes** block will not be provided to the *DataReaders* as a set.

See also: the **coherent\_access** field in the [46.6 PRESENTATION QosPolicy on page 760](#) and the **coherent\_set\_info** field in [41.6 The SampleInfo Structure on page 676](#).

## 31.11 Waiting for Acknowledgments in a DataWriter

The *DataWriter's* **wait\_for\_acknowledgments()** operation blocks the calling thread until either all data written by the reliable *DataWriter* is acknowledged by (a) all reliable *DataReaders* that are matched and alive *and* (b) by all required subscriptions (see [31.13 Required Subscriptions on page 424](#)), or until the duration specified by the **max\_wait** parameter elapses, whichever happens first.

Note that if a thread is blocked in the call to **wait\_for\_acknowledgments()** on a *DataWriter* and a different thread writes new DDS samples on the same *DataWriter*, the new DDS samples must be acknowledged before unblocking the thread waiting on **wait\_for\_acknowledgments()**.

```
DDS_ReturnCode_t wait_for_acknowledgments (
    const DDS_Duration_t & max_wait)
```

This operation returns **DDS\_RETCODE\_OK** if all the DDS samples were acknowledged, or **DDS\_RETCODE\_TIMEOUT** if the **max\_wait** duration expired first.

If the *DataWriter* does not have its [47.21 RELIABILITY QosPolicy on page 845](#) **kind** set to **RELIABLE**, the operation will immediately return **DDS\_RETCODE\_OK**.

There is a similar operation available at the *Publisher* level, see [30.7 Waiting for Acknowledgments in a Publisher on page 387](#).

The reliability protocol used by *Connex*t is discussed in [Reliability Models for Sending Data \(Chapter 32 on page 446\)](#). The application acknowledgment mechanism is discussed in [31.12 Application Acknowledgment below](#) and [Guaranteed Delivery of Data \(Chapter 33 on page 485\)](#).

## 31.12 Application Acknowledgment

The [47.21 RELIABILITY QosPolicy on page 845](#) determines whether or not data published by a *DataWriter* will be reliably delivered by *Connex*t to matching *DataReaders*. The reliability protocol used by *Connex*t is discussed in [Reliability Models for Sending Data \(Chapter 32 on page 446\)](#).

With protocol-level reliability alone, the producing application knows that the information is received by the protocol layer on the consuming side. However, the producing application cannot be certain that the consuming application read that information or was able to successfully understand and process it. The information could arrive in the consumer's protocol stack and be placed in the *DataReader* cache but the consuming application could either crash before it reads it from the cache, not read its cache, or read the cache using queries or conditions that prevent that particular DDS data sample from being accessed. Furthermore, the consuming application could access the DDS sample, but not be able to interpret its meaning or process it in the intended way.

The mechanism to let a *DataWriter* know to keep the DDS sample around, not just until it has been acknowledged by the reliability protocol, but until the application has been able to process the DDS sample is aptly called *Application Acknowledgment*. A reliable *DataWriter* will keep the DDS samples until the application acknowledges the DDS samples. When the subscriber application is restarted, the middleware will know that the application did not acknowledge successfully processing the DDS samples and will resend them.

### 31.12.1 Application Acknowledgment Kinds

*Connex*t supports *three* kinds of application acknowledgment, which is configured in the [47.21 RELIABILITY QosPolicy on page 845](#)):

1. **DDS\_PROTOCOL\_ACKNOWLEDGMENT\_MODE** (Default): In essence, this mode is identical to using no application-level acknowledgment. DDS samples are acknowledged according to the Real-Time Publish-Subscribe (RTPS) reliability protocol. RTPS AckNack messages will

acknowledge that the middleware received the DDS sample.

2. `DDS_APPLICATION_AUTO_ACKNOWLEDGMENT_MODE`: DDS samples are automatically acknowledged by the middleware after the subscribing application accesses them, either through calling `take()` or `read()` on the DDS sample. If the `read()` or `take()` operation loans the samples, the acknowledgment is done after the `return_loan()` operation is called. Otherwise, for `read()` or `take()` operations that make a copy, acknowledgment is done after the `read()` or `take()` operations are executed.
3. `DDS_APPLICATION_EXPLICIT_ACKNOWLEDGMENT_MODE`: DDS samples are acknowledged after the subscribing application explicitly calls `acknowledge` on the DDS sample. This can be done by either calling the *DataReader's* `acknowledge_sample()` or `acknowledge_all()` operations. When using `acknowledge_sample()`, the application will provide the `DDS_SampleInfo` to identify the DDS sample being acknowledge. When using `acknowledge_all`, all the DDS samples that have been read or taken by the reader will be acknowledged.

**Note:** Even in `DDS_APPLICATION_EXPLICIT_ACKNOWLEDGMENT_MODE`, some DDS samples may be automatically acknowledged. This is the case when DDS samples are filtered out by the reader using time-based filter, or using content filters. Additionally, when the reader is explicitly configured to use `KEEP_LAST` history kind, DDS samples may be replaced in the reader queue due to resource constraints. In that case, the DDS sample will be automatically acknowledged by the middleware if it has not been read by the application before it was replaced. To truly guarantee successful processing of DDS samples, it is recommended to use `KEEP_ALL` history kind.

## 31.12.2 Explicitly Acknowledging a Single DDS Sample (C++)

```
void MyReaderListener::on_data_available(DDSDataReader *reader)
{
    Foo sample;
    DDS_SampleInfo info;
    FooDataReader* fooReader = FooDataReader::narrow(reader);
    DDS_ReturnCode_t retcode = fooReader->take_next_sample(
        sample, info);
    if (retcode == DDS_RETCODE_OK) {
        if (info.valid_data) {
            // Process sample
            ...
            retcode = reader->acknowledge_sample(info);
            if (retcode != DDS_RETCODE_OK) {
                // Error
            }
        }
    } else {
        // Not OK or NO DATA
    }
}
```

### 31.12.3 Explicitly Acknowledging All DDS samples (C++)

```
void MyReaderListener::on_data_available(DDSDataReader *reader)
{
    ...
    // Loop while samples available
    for(;;) {
        retcode = string_reader->take_next_sample(
            sample, info);
        if (retcode == DDS_RETCODE_NO_DATA) {
            // No more samples
            break;
        }
        // Process sample
        ...
    }
    retcode = reader->acknowledge_all();
    if (retcode != DDS_RETCODE_OK) {
        // Error
    }
}
}
```

### 31.12.4 Notification of Delivery with Application Acknowledgment

A *DataWriter* can get notification of delivery with Application Acknowledgment using two different mechanisms:

- *DataWriter's* `wait_for_acknowledgments()` operation

A *DataWriter* can use the `wait_for_acknowledgments()` operation to be notified when all the DDS samples in the *DataWriter's* queue have been acknowledged. See [31.11 Waiting for Acknowledgments in a DataWriter on page 417](#).

```
retCode = fooWriter->write(sample, DDS_HANDLE_NIL);
if (retCode != DDS_RETCODE_OK) {
    // Error
}
retcode = writer->wait_for_acknowledgments(timeout);
if (retCode != DDS_RETCODE_OK) {
    if (retCode == DDS_RETCODE_TIMEOUT) {
        // Timeout: Sample not acknowledged yet
    } else {
        // Error
    }
}
}
```

Using `wait_for_acknowledgments()` does not provide a way to get delivery notifications on a per *DataReader* and DDS sample basis. If your application requires acknowledgment of message receipt, use the second mechanism described below.

- *DataWriter's* listener callback `on_application_acknowledgment()`

An application can install a *DataWriter* listener callback `on_application_acknowledgment()` to receive a notification when a DDS sample is acknowledged by a *DataReader*. As part of this notification, you can access:

- The subscription handle of the acknowledging *DataReader*.
- The Identity of the DDS sample being acknowledged.
- The response data associated with the DDS sample being acknowledged.

For more information, see [31.6.1 APPLICATION\\_ACKNOWLEDGMENT\\_STATUS](#) on page 398.

## 31.12.5 Application-Level Acknowledgment Protocol

When the subscribing application confirms it has successfully processed a DDS sample, an AppAck RTPS message is sent to the publishing application. This message will be resent until the publishing application confirms receipt of the AppAck message by sending an AppAckConf RTPS message. See [Figure 31.2: AppAck RTPS Messages Sent when Application Acknowledges a DDS Sample](#) below through [Figure 31.4: AppAck RTPS Messages Sent as a Sequence of Intervals, Combined to Optimize for Bandwidth on the next page](#).

Figure 31.2: AppAck RTPS Messages Sent when Application Acknowledges a DDS Sample

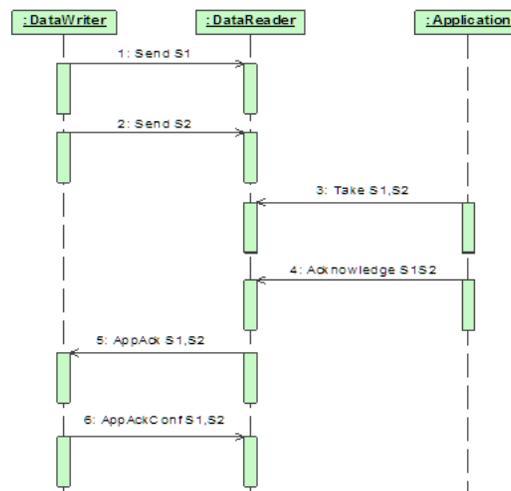

Figure 31.3: AppAck RTPS Messages Resent Until Acknowledged Through AppAckConf RTPS Message

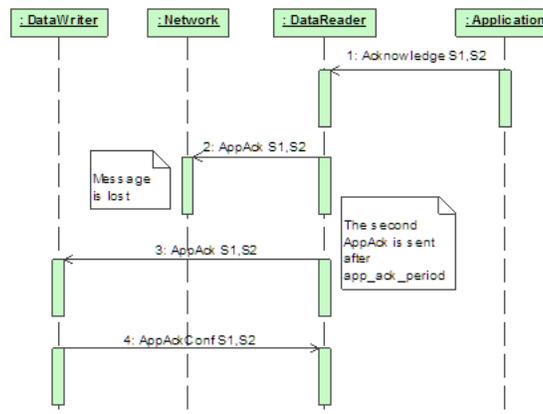

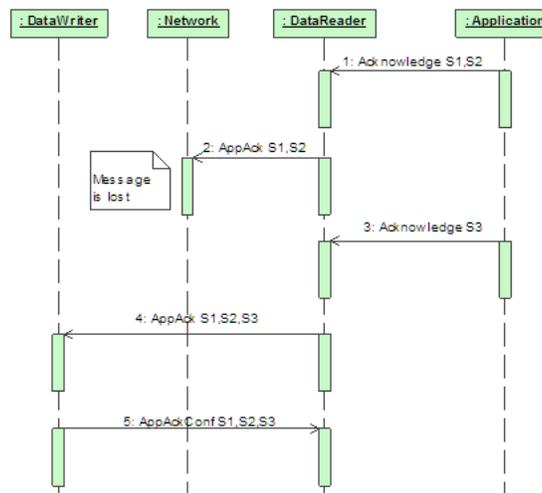

Figure 31.4: AppAck RTPS Messages Sent as a Sequence of Intervals, Combined to Optimize for Bandwidth

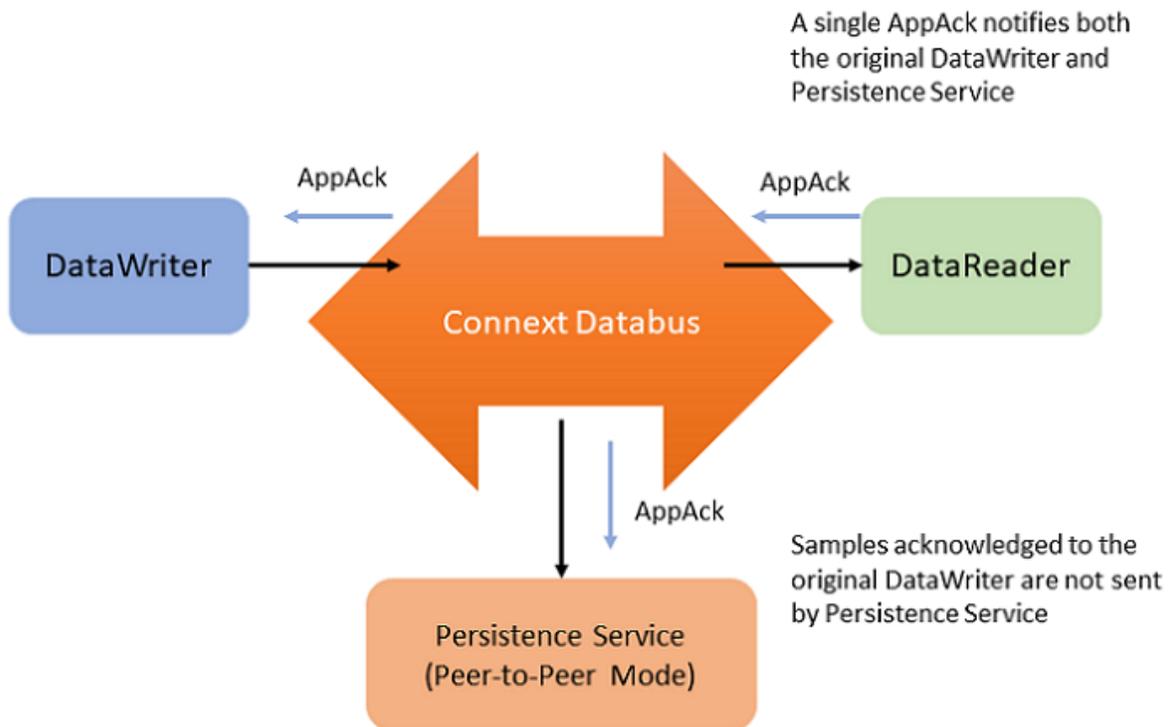

## 31.12.6 Periodic and Non-Periodic AppAck Messages

You can configure whether AppAck RTPS messages are sent immediately or periodically through the [48.1 DATA\\_READER\\_PROTOCOL QosPolicy \(DDS Extension\)](#) on page 871. The `samples_per_app_ack` on page 874 (in [Table 48.2 DDS\\_RtpsReliableReaderProtocol\\_t](#)) determines the minimum number of DDS samples acknowledged by one application-level Acknowledgment message. The middleware will not send an AppAck message until it has at least this many DDS samples pending acknowledgment. By default, `samples_per_app_ack` is 1 and the AppAck RTPS message is sent immediately. Independently, the `app_ack_period` on page 874 (in [Table 48.2 DDS\\_RtpsReliableReaderProtocol\\_t](#)) determines the rate at which a *DataReader* will send AppAck messages.

## 31.12.7 Application Acknowledgment and Persistence Service

Application Acknowledgment is fully supported by *RTI Persistence Service*. The combination of Application Acknowledgment and *Persistence Service* is actually a common configuration. In addition to keeping DDS samples available until fully acknowledged, *Persistence Service*, when used in peer-to-peer mode, can take advantage of AppAck messages to avoid sending duplicate messages to the subscribing application. Because AppAck messages are sent to all matching writers, when the subscriber acknowledges the original publisher, *Persistence Service* will also be notified of this event and will not send out duplicate messages. This is illustrated in [Figure 31.5: Application Acknowledgment and Persistence Service](#) below.

Figure 31.5: Application Acknowledgment and Persistence Service

## 31.12.8 Application Acknowledgment and Routing Service

Application Acknowledgment is supported by *RTI Routing Service*: That is, *Routing Service* will acknowledge the DDS sample it has processed. *Routing Service* is an active participant in the *Connex* system and not transparent to the publisher or subscriber. As such, *Routing Service* will acknowledge to the publisher, and the subscriber will acknowledge to *Routing Service*. However, the publisher will not get a notification from the subscriber directly.

## 31.13 Required Subscriptions

The [47.9 DURABILITY QoSPolicy on page 809](#) specifies whether acknowledged DDS samples need to be kept in the *DataWriter's* queue and made available to late-joining applications. When a late joining application is discovered, available DDS samples will be sent to the late joiner. With the Durability QoS alone, there is no way to specify or characterize the intended consumers of the information and you do not have control over which DDS samples will be kept for late-joining applications. If while waiting for late-joining applications, the middleware needs to free up DDS samples, it will reclaim DDS samples if they have been previously acknowledged by active/matching readers.

There are scenarios where you know a priori that a particular set of applications will join the system: e.g., a logging service or a known processing application. The *Required Subscription* feature is designed to keep data until these known late joining applications acknowledge the data.

Another use case is when *DataReaders* become temporarily inactive due to not responding to heartbeats, or when the subscriber temporarily became disconnected and purged from the discovery database. In both cases, the *DataWriter* will no longer keep the DDS sample for this *DataReader*. The *Required Subscription* feature will keep the data until these known *DataReaders* have acknowledged the data.

To use Required Subscriptions, the *DataReaders* and *DataWriters* must have their [47.21 RELIABILITY QoSPolicy on page 845](#) **kind** set to RELIABLE.

### 31.13.1 Named, Required and Durable Subscriptions

Before describing the Required Subscriptions, it is important to understand a few concepts:

- **Named Subscription:** Through the [47.11 ENTITY\\_NAME QoSPolicy \(DDS Extension\) on page 817](#), each *DataReader* can be given a specific name. This name can be used by tools to identify a specific *DataReader*. Additionally, the *DataReader* can be given a `role_name`. For example: LOG\_APP\_1 *DataReader* belongs to the logger applications (`role_name = "LOGGER"`).
- **Required Subscription** is a named subscription to which a *DataWriter* is configured to deliver data to. This is true even if the *DataReaders* serving those subscriptions are not available yet. The *DataWriter* must store the DDS sample until it has been acknowledged by all active reliable *DataReaders* and acknowledged by all required subscriptions. The *DataWriter* is not waiting for a specific *DataReader*, rather it is waiting for *DataReaders* belonging to the required subscription by setting their `role_name` to the subscription name.
- **Durable Subscription** is a required subscription where DDS samples are stored and forwarded by an external service. In this case, the required subscription is served by *RTI Persistence Service*. See [74.9 Configuring Durable Subscriptions in Persistence Service on page 1226](#).

## 31.13.2 Durability QoS and Required Subscriptions

The [47.9 DURABILITY QoS Policy on page 809](#) and the Required Subscriptions feature complement each other.

The `DurabilityQoSPolicy` determines whether or not *Connex* will store and deliver previously acknowledged DDS samples to new *DataReaders* that join the network later. You can specify to either *not* make the DDS samples available (`DDS_VOLATILE_DURABILITY_QOS` kind), or to make them available and declare you are storing the DDS samples in memory (`DDS_TRANSIENT_LOCAL_DURABILITY_QOS` or `DDS_TRANSIENT_DURABILITY_QOS` kind) or in permanent storage (`DDS_PERSISTENT_DURABILITY_QOS`).

Required subscriptions help answer the question of *when* a DDS sample is considered acknowledged before the `DurabilityQoSPolicy` determines whether to keep it. When required subscriptions are used, a DDS sample is considered acknowledged by a *DataWriter* when both the active *DataReaders* and a quorum of required subscriptions have acknowledged the DDS sample. (Acknowledging a DDS sample can be done either at the protocol or application level—see [31.12 Application Acknowledgment on page 418](#)).

### 31.13.3 Required Subscriptions Configuration

Each *DataReader* can be configured to be part of a named subscription, by giving it a **role\_name** using the [47.11 ENTITY\\_NAME QoS Policy \(DDS Extension\) on page 817](#). A *DataWriter* can then be configured using the [47.1 AVAILABILITY QoS Policy \(DDS Extension\) on page 769](#) (**required\_matched\_endpoint\_groups**) with a list of required named subscriptions identified by the **role\_name**. Additionally, the *DataWriter* can be configured with a *quorum* or minimum number of *DataReaders* from a given named subscription that must receive a DDS sample.

When configured with a list of required subscriptions, a *DataWriter* will store a DDS sample until the DDS sample is acknowledged by all active reliable *DataReaders*, as well as all required subscriptions. When a quorum is specified, a minimum number of *DataReaders* of the required subscription must acknowledge a DDS sample in order for the DDS sample to be considered acknowledged. Specifying a quorum provides a level of redundancy in the system as multiple applications or services acknowledge they have received the DDS sample. Each individual *DataReader* is identified using its own virtual GUID (see [48.1 DATA\\_READER\\_PROTOCOL QoS Policy \(DDS Extension\) on page 871](#)).

## 31.14 Managing Instances (Working with Keyed Data Types)

This section applies only to data types that use keys; see [Chapter 8 DDS Samples, Instances, and Keys on page 17](#). Using the following operations for non-keyed types has no effect. This section describes how instances work on *DataWriters*. See also [Chapter 19 Working with Instances on page 257](#).

*Topics* come in two flavors: those whose associated data type has specified some fields as defining the ‘key,’ and those whose associated data type has not. An example of a data-type that specifies key fields is shown in [Figure 31.6: Data Type with a Key on the next page](#).

Figure 31.6: Data Type with a Key

```
typedef struct Flight {
    @key int32    flightId;
    string departureAirport;
    string arrivalAirport;
    Time_t departureTime;
    Time_t estimatedArrivalTime;
    Location_t currentPosition;
};
```

### 31.14.1 Writing Instances

If the data type has some fields that act as a ‘key,’ the *Topic* contains one or more instances whose values can be independently maintained. In [Figure 31.6: Data Type with a Key](#) above, the **flightId** is the ‘key’. Different flights will have different values for the key. Each flight is an instance of the *Topic*. Each **write()** (or **write()** variation such as **write\_w\_timestamp()**) will update the information about a single flight—meaning that when a *DataWriter* calls **write()**, the *DataWriter* is updating the instance represented by the **flightId**.

When a *DataWriter* updates an instance by calling **write()**, a sample of that instance is sent to matching *DataReaders*, and the *DataReaders* consider the instance to be ALIVE.

If the *DataWriter*’s [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#) specifies a **max\_instances** limit that is not infinite, the limit will apply when writing. If a *DataWriter* writes an instance that it has not written before, and it has already reached the **max\_instances** limit, it will try to reclaim the memory used by an existing instance. The rules for which instances it can replace are described in [31.14.7 Instance Memory Management on page 430](#).

If the *DataWriter* cannot reclaim the memory used by an existing instance, the **write()** call will fail. For more information on the behavior of the **write()** call when the **max\_instances** limit is hit, see [31.8.2 write\(\) behavior with KEEP\\_LAST and KEEP\\_ALL on page 413](#).

### 31.14.2 Registering Instances

If your data type has a key, you may improve performance of any operation that modifies the instance, such as any variation of **write()** or **dispose()**, by providing a non-NIL instance handle. An instance handle contains the pre-calculated instance keyhash so that it does not need to be calculated again. The instance handle for an instance can be retrieved once the instance is registered.

A *DataWriter* can register and retrieve an instance handle for an instance in two ways:

- Explicitly, with the **register\_instance()** operation. The **register\_instance()** operation provides a handle to the instance (of type **DDS\_InstanceHandle\_t**) that can be used later to refer to the instance.

- Implicitly by providing a NIL instance handle to one of the variations of the **write()** or **dispose()** calls. After one of these calls has been made, the instance handle for the now-registered instance can be retrieved using the *DataWriter* **lookup\_instance()** call.

Once you have an instance handle, you can use it while writing to avoid calculating the instance key-hash in every write call. This performance improvement may be significant if your data is relatively small or your key fields are relatively complex. (If your data itself is large or complex, the time to calculate the keyhash may be insignificant relative to the time to serialize your data.)

You can register any number of instances up to the maximum number of instances configured in the *DataWriter*'s [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#). Explicit instance registration is completely optional. Note that registration through the **register\_instance()** call only affects the *DataWriter*: matching *DataReaders* are not notified that the instance is **ALIVE** when the *DataWriter* registers the instance. An instance is only recognized as **ALIVE** when a *DataWriter* writes the instance. When an application registers instances and uses the instance handles for increased performance, it must keep a mapping between instance handles and instances. See the **Warning** below.

**Figure 31.7: Explicitly Registering an Instance**

```
Flight myFlight;
// writer is a previously-created FlightDataWriter
myFlight.flightId = 265;
DDS_InstanceHandle_t f1265Handle =
writer->register_instance(myFlight);
...
// Each time we update the flight, we can pass the handle
myFlight.departureAirport    = "SJC";
myFlight.arrivalAirport      = "LAX";
myFlight.departureTime       = {120000, 0};
myFlight.estimatedArrivalTime = {130200, 0};
myFlight.currentPosition     = { {37, 20}, {121, 53} };
if (writer->write(myFlight, f1265Handle) != DDS_RETCODE_OK) {
// ... handle error
}
// The writer can declare that it will no longer update information about
// this flight by unregistering itself from the instance

if (writer->unregister_instance(myFlight, f1265Handle) !=
DDS_RETCODE_OK) {
// ... handle error
}
```

**Warning:** If you decide to manage instance handles using your own application logic, make sure you keep a correct mapping between the instance and instance handle. If you pass the wrong instance handle when writing data, *Connex* will assume that you are writing the instance associated with the handle. It does not check that the key fields match that handle, because that would negate the performance improvement from passing the handle. Passing

the wrong instance handle can lead to strange behavior, because *Connex*t will treat your data sample as though it belongs to the wrong instance.

For example, if you have the History QoS Policy **kind** set to `KEEP_LAST` and **depth** set to 1 on the *DataReader*, *Connex*t should keep the last sample for each instance. But if you pass the wrong instance handle when writing, the *DataReader* will overwrite the wrong sample (in the wrong instance). As a result, a *DataReader* will not get updates for the instance it expects. An incorrect instance handle will affect all QoS policies that are applied per instance; see [19.2.1 QoS Policies that are Applied per Instance on page 264](#).

When you are done using an instance, you can unregister it. See [31.14.4 Unregistering Instances on the next page](#).

### 31.14.3 Disposing Instances

The **dispose()** operation informs *DataReaders* that, as far as the *DataWriter* knows, the instance no longer exists and can be considered “not alive.” When the **dispose()** operation is called, the instance state stored in the **DDS\_SampleInfo** structure, accessed through *DataReaders*, will change to **NOT\_ALIVE\_DISPOSED** for that particular instance.

Often, systems use the **NOT\_ALIVE\_DISPOSED** state to indicate that some object is completely gone from the system. For example, in a flight tracking system, when a flight lands, a *DataWriter* may dispose of the instance corresponding to the flight. In that case, all *DataReaders* who are monitoring the flight will see the instance state change to **NOT\_ALIVE\_DISPOSED**, indicating that the flight has landed.

**Note:** If a *DataWriter* calls **dispose()**, it does not give up ownership of the instance (unlike when it calls **unregister\_instance()**, in which case it is declaring that it will no longer have any updates for the instance and therefore does give up ownership of the instance to other *DataWriters* that may still be actively updating the instance).

**Attention:** Disposing does not free up memory by default. For instance, when the *DataWriter* calls **dispose()** to indicate that a flight has landed, it must keep the dispose message in its queue so all matching *DataReaders* get notified that the flight has landed (i.e., has been disposed). Also, in terms of memory management, *Connex*t may reclaim unregistered instances before disposed ones, or not reclaim disposed instances at all, depending on your QoS settings. See [31.14.7 Instance Memory Management on page 430](#).

See also:

- [47.31.1 Unregistering vs. Disposing on page 867](#)
- [47.5.5 Propagating Serialized Keys with Disposed-Instance Notifications on page 796](#)

- [47.31.2 Autodisposing Unregistered Instances on page 868](#)

## 31.14.4 Unregistering Instances

The `unregister_instance()` operation informs *DataReaders* that the *DataWriter* is no longer updating the instance. When a *DataWriter* will no longer update an instance, you can unregister it. To unregister a *DataWriter* from an instance, use the *DataWriter*'s `unregister_instance()` operation. Unregistering tells *Connex*t that the *DataWriter* has no more information on this instance; thus, it does not intend to modify that instance anymore, allowing *Connex*t to recover any resources it allocated for the instance.

`unregister_instance()` should only be used on instances that have been previously registered. Instances can be registered explicitly with the `register_instance()` operation, or implicitly with any variation of the `write()` or `dispose()` operations. See [Figure 31.7: Explicitly Registering an Instance on page 427](#).

Once all *DataWriters* have unregistered from an instance, the matched *DataReaders* will eventually get an indication that the instance no longer has any *DataWriters*. This is communicated to the subscribing application by means of the `DDS_SampleInfo` that accompanies each DDS sample (see [41.6 The SampleInfo Structure on page 676](#)). Once there are no *DataWriters* for the instance, the *DataReader* will see the value of `DDS_InstanceStateKind` for that instance to be `NOT_ALIVE_NO_WRITERS`.

Note that *DataReaders* can't distinguish between a scenario where all *DataWriters* explicitly unregister from an instance and a scenario where all *DataWriters* have lost liveliness. For more information on *DataWriter* liveliness, see the [47.15 LIVELINESS QoS Policy on page 825](#).

The `unregister_instance()` operation may affect the ownership of the instance (see the [47.17 OWNERSHIP QoS Policy on page 833](#)). If the **DataWriter** was the exclusive owner of the instance, then calling `unregister_instance()` relinquishes that ownership, and another *DataWriter* can become the exclusive owner of the instance. (In contrast, if a *DataWriter* calls `dispose()`, it does not give up ownership of the instance.)

The `unregister_instance()` operation indicates only that a particular *DataWriter* no longer has any information/data on an instance and thus no longer has anything to say about the instance. It does not indicate that anything about the instance itself has changed, such as its existence or the associated data. For example, a *DataWriter* that is tracking a flight may unregister from an instance when the flight goes out of range—this does not mean that the position of the flight has changed or that the flight has landed, just that the *DataWriter* no longer has any knowledge of the flight; other *DataWriters* may still update the flight's position.

The `autodispose_unregistered_instances` field in the [47.31 WRITER\\_DATA\\_LIFECYCLE QoS Policy on page 866](#) controls whether instances are automatically disposed of when they are unregistered. (By default, they are not. See [47.31.2 Autodisposing Unregistered Instances on page 868](#).) When this QoS is true and the *DataWriter* unregisters from an instance, two samples are sent to the *DataReader* to notify it that the instance is both unregistered and disposed. The rules about which instance memory can be reclaimed are documented in [31.14.7 Instance Memory Management on the next page](#).

The `unregister_instance()` operation adds one sample (or two) to the *DataWriter* queue, so the behavior of `unregister_instance()` with regards to `KEEP_LAST` and `KEEP_ALL` is the same as for the `write()` operation. See [31.8.2 write\(\) behavior with KEEP\\_LAST and KEEP\\_ALL on page 413](#). (Two samples are added if `autodispose_unregistered_instances` is set to `TRUE`; *Connex* makes a dispose and an unregister sample. See [autodispose\\_unregistered\\_instances on page 867](#) in the [47.31 WRITER\\_DATA\\_LIFECYCLE QoS Policy on page 866](#).)

See also:

- [47.31.1 Unregistering vs. Disposing on page 867](#)
- [47.31.2 Autodisposing Unregistered Instances on page 868](#)

## 31.14.5 Looking up an Instance Handle

Some operations, such as `write()`, accept an `instance_handle` parameter. If you need to get such a handle, you can call the *FooDataWriter*'s `lookup_instance()` operation, which takes an instance as a parameter and returns a handle to that instance. This is useful only for keyed data types.

```
DDS_InstanceHandle_t lookup_instance (const Foo & key_holder)
```

The instance must have already been registered, written, or disposed. If the instance is not known to the *DataWriter*, this operation returns `DDS_HANDLE_NIL`.

## 31.14.6 Getting the Key Value for an Instance

Once you have an instance handle (using `register_instance()` or `lookup_instance()`), you can use the *DataWriter*'s `get_key_value()` operation to retrieve the value of the key of the corresponding instance. The key fields of the data structure passed into `get_key_value()` will be filled out with the original values used to generate the instance handle. The key fields are defined when the data type is defined (see [Chapter 8 DDS Samples, Instances, and Keys on page 17](#)).

Following our example in [Figure 31.7: Explicitly Registering an Instance on page 427](#), `register_instance()` returns a `DDS_InstanceHandle_t` that can be used in the call to the *FlightDataWriter*'s `get_key_value()` operation. The value of the key is returned in a structure of type `Flight` with the `flightId` field filled in with the integer 265.

See also: [47.5.5 Propagating Serialized Keys with Disposed-Instance Notifications on page 796](#).

## 31.14.7 Instance Memory Management

In *Connex*, memory is primarily pre-allocated when creating entities. When data is keyed, the memory associated with each instance used for storing instance-specific metadata is allocated when the *DataWriter* is created. Memory is not freed at runtime, unless you delete an entity. Instead, memory is made available to be reused by the *DataWriter*, or 'reclaimed'.

Instance memory in the *DataWriter* is reclaimed two ways:

- **Lazily (Default):** when a resource limit such as **max\_instances** is hit. Only once this limit is hit will *Connex*t reclaim memory as described in the following sections.
- **Proactively (Non-Default):** after a time delay, configured by **autopurge\_unregister\_instance\_delay** or **autopurge\_disposed\_instances\_delay**, as long as all samples of that instance are fully-acknowledged (see [31.8.2 write\(\) behavior with KEEP\\_LAST and KEEP\\_ALL on page 413](#)). In this case, the instance data is purged, freeing up memory for future use (i.e., for "reclaiming").

In the default case, *Connex*t has to decide which instances to replace first. This is controlled by the following QoS policies and settings.

### 31.14.7.1 WriterDataLifecycle: autopurge\_unregister\_instances\_delay

When **autopurge\_unregister\_instances\_delay** in the [47.31 WRITER\\_DATA\\_LIFECYCLE QoS Policy on page 866](#) is 0, *Connex*t will clean up all the resources associated with an unregistered instance (most notably, the DDS sample history of non-volatile *DataWriters*) when all the instance's samples have been acknowledged by all its live *DataReaders*, including the sample that indicates the unregistration. By default, **autopurge\_unregister\_instances\_delay** is disabled (the delay is INFINITE). If the delay is set to zero, the *DataWriter* will clean up as soon as all the samples are acknowledged after the call to **unregister\_instance()**. A non-zero value for the delay can be useful in two ways:

- To keep the historical DDS samples for late-joiners for a period of time.
- In the context of the builtin discovery *DataWriters*, if the applications temporarily lose the connection before the unregistration (which represents the remote entity destruction), to provide the DDS samples that indicate the dispose and unregister actions once the connection is reestablished.

*This delay can also be set for discovery data through these fields in the [44.3 DISCOVERY\\_CONFIG QoS Policy \(DDS Extension\) on page 703](#):*

- **publication\_writer\_data\_lifecycle.autopurge\_unregister\_instances\_delay**
- **subscription\_writer\_data\_lifecycle.autopurge\_unregister\_instances\_delay**
- **publication\_writer\_data\_lifecycle.autopurge\_disposed\_instances\_delay**
- **subscription\_writer\_data\_lifecycle.autopurge\_disposed\_instances\_delay**

### 31.14.7.2 DataWriterResourceLimits: replace\_empty\_instances

The **replace\_empty\_instances** field in the [47.6 DATA\\_WRITER\\_RESOURCE\\_LIMITS QoS Policy \(DDS Extension\) on page 800](#) defines whether instances with no samples in the *DataWriter* queue be replaced first, regardless of their instance state. If there are multiple empty instances, **replace\_empty\_**

**instances** will replace unregistered instances, then disposed instances, then alive instances. If **replace\_empty\_instances** is true, empty instances will always be replaced first before any instance that may qualify for replacement based on the **instance\_replacement** field in the [47.6 DATA\\_WRITER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\)](#) on page 800.

Values: true/false

### 31.14.7.3 DataWriterResourceLimits: instance\_replacement

This **instance\_replacement** field in the [47.6 DATA\\_WRITER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\)](#) on page 800 defines which instance states can be replaced, and the order in which they are allowed to be replaced. This setting takes effect if all samples for an instance are fully acknowledged.

Values:

- DDS\_UNREGISTERED\_INSTANCE\_REPLACEMENT
- DDS\_ALIVE\_INSTANCE\_REPLACEMENT
- DDS\_DISPOSED\_INSTANCE\_REPLACEMENT
- DDS\_ALIVE\_THEN\_DISPOSED\_INSTANCE\_REPLACEMENT
- DDS\_DISPOSED\_THEN\_ALIVE\_INSTANCE\_REPLACEMENT
- DDS\_ALIVE\_OR\_DISPOSED\_INSTANCE\_REPLACEMENT

**Warning:** Unregistered instances are always replaced first even if you don't choose DDS\_UNREGISTERED\_INSTANCE\_REPLACEMENT. Because unregistering an instance indicates that the *DataWriter* will no longer update the instance, it is assumed that reclaiming these resources first will avoid information loss in your system.

When a *DataWriter* disposes an instance, it cannot replace the memory related to that instance unless **autopurge\_disposed\_instances\_delay** is finite, the **instance\_replacement** field in the [47.6 DATA\\_WRITER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\)](#) on page 800 indicates that disposed instances can be replaced when instance resource limits are reached, or the instance is empty and **replace\_empty\_instances** is true.

See also:

- [47.31.1 Unregistering vs. Disposing on page 867](#)
- [47.31.2 Autodisposing Unregistered Instances on page 868](#)

## 31.14.8 Consequences of Unpurged Dispose Messages

There are consequences of having many unpurged dispose messages in the *DataWriter's* queue. If the *DataWriter's* [47.9 DURABILITY QosPolicy on page 809](#) **kind** is not VOLATILE, those dispose

messages will be delivered to late-joining *DataReaders*, which may cause an unexpected spike in network traffic. In addition, the *DataReaders* will not notify the application about those previously-disposed instances, because by default *DataReaders* will not propagate dispose messages for instances that were previously unknown. (This behavior can be changed by using the **propagate\_dispose\_of\_unregistered\_instances** QoS setting on the *DataReader*.)

Failing to purge disposed instances will cause similar behavior when using TopicQueries. When the *DataWriter* sends the response to the TopicQuery, it will include the unpurged dispose messages, causing high network traffic. In general, all dispose and unregister messages always pass filters (associated with ContentFilteredTopics, TopicQueries, or QueryConditions). This means that even if a TopicQuery’s filter expression only specifies a specific key value or set of key values, all dispose messages for all instances in the *DataWriter* queue will be sent in response to the TopicQuery. To avoid this when using TopicQueries, use the special statement at the beginning of the query: “@instance\_state = ALIVE AND” followed by the rest of the expression. This prevents the *DataWriter* from sending not-alive samples.

See also:

- [47.5.5 Propagating Serialized Keys with Disposed-Instance Notifications on page 796](#)
- [47.31.2 Autodisposing Unregistered Instances on page 868](#)

## 31.14.9 Consequences of DataWriters Reclaiming Disposed Instances

If your network is subject to disconnections, and disposed instances are purged, it’s possible that a dispose message is not received by every *DataReader*, leading to *DataReaders* recognizing different instance states. This happens if your network disconnection is long enough for a reliable *DataReader* to be marked as inactive and the disposed instance is purged during the disconnection. If the disposed message is not purged during the disconnection, it is still possible for the dispose message to be delivered after reconnection if the [47.9 DURABILITY QoSPolicy on page 809](#) is not VOLATILE.

If you have one or more *RTI Routing Service* applications in your network, leading to multiple places where instance state gets cached and might be reclaimed, it is even more likely that a dispose message might not be received by every *DataReader*.

## 31.15 Setting DataWriter QoS Policies

The *DataWriter*’s QoS Policies control its resources and behavior.

The **DDS\_DataWriterQos** structure has the following format:

```
DDS_DataWriterQos struct {
    DDS_DurabilityQoSPolicy           durability;
    DDS_DurabilityServiceQoSPolicy    durability_service;
    DDS_DeadlineQoSPolicy             deadline;
    DDS_LatencyBudgetQoSPolicy        latency_budget;
    DDS_LivelinessQoSPolicy           liveliness;
```

```

DDS_ReliabilityQosPolicy      reliability;
DDS_DestinationOrderQosPolicy destination_order;
DDS_HistoryQosPolicy         history;
DDS_ResourceLimitsQosPolicy   resource_limits;
DDS_TransportPriorityQosPolicy transport_priority;
DDS_LifespanQosPolicy        lifespan;
DDS_UserDataQosPolicy        user_data;
DDS_OwnershipQosPolicy       ownership;
DDS_OwnershipStrengthQosPolicy ownership_strength;
DDS_WriterDataLifecycleQosPolicy writer_data_lifecycle;
DDS_DataRepresentationQosPolicy representation;
DDS_DataTagQosPolicy         data_tags;
// extensions to the DDS standard:
DDS_DataWriterResourceLimitsQosPolicy writer_resource_limits;
DDS_DataWriterProtocolQosPolicy protocol;
DDS_TransportSelectionQosPolicy transport_selection;
DDS_TransportUnicastQosPolicy unicast;
DDS_PublishModeQosPolicy     publish_mode;
DDS_PropertyQosPolicy        property;
DDS_ServiceQosPolicy         service;
DDS_BatchQosPolicy           batch;
DDS_MultiChannelQosPolicy    multi_channel;
DDS_AvailabilityQosPolicy    availability;
DDS_EntityNameQosPolicy      publication_name;
DDS_TopicQueryDispatchQosPolicy topic_query_dispatch;
    DDS_DataWriterTransferModeQosPolicy transfer_mode;
DDS_TypeSupportQosPolicy     type_support;
} DDS_DataWriterQos;

```

**Note:** `set_qos()` cannot always be used within a listener callback, see [15.8.8.1 Restricted Operations in Listener Callbacks on page 57](#).

[Table 31.16 DataWriter QosPolicies](#) summarizes the meaning of each policy. (They appear alphabetically in the table.) For information on *why* you would want to change a particular QosPolicy, see the referenced section. For defaults and valid ranges, please refer to the API Reference HTML documentation.

Table 31.16 DataWriter QoS Policies

QoS Policy	Description
Availability	<p>This QoS policy is used in the context of two features:</p> <p><a href="#">47.1.1 Availability QoS Policy and Collaborative DataWriters on page 770</a></p> <p><a href="#">47.1 AVAILABILITY QoS Policy (DDS Extension) on page 769</a></p> <p>For Collaborative DataWriters, Availability specifies the group of <i>DataWriters</i> expected to collaboratively provide data and the timeouts that control when to allow data to be available that may skip DDS samples.</p> <p>For Required Subscriptions, Availability configures a set of Required Subscriptions on a <i>DataWriter</i>.</p> <p>See <a href="#">47.1 AVAILABILITY QoS Policy (DDS Extension) on page 769</a></p>
Batch	<p>Specifies and configures the mechanism that allows <i>Connex</i>t to collect multiple DDS user data samples to be sent in a single network packet, to take advantage of the efficiency of sending larger packets and thus increase effective throughput. See <a href="#">47.2 BATCH QoS Policy (DDS Extension) on page 773</a>.</p>
DataRepresentation	<p>Specifies which version of the Extended Common Data Representation (CDR) is offered. See <a href="#">47.3 DATA_REPRESENTATION QoS Policy on page 780</a>.</p>
DataTag	<p>A sequence of (name, value) string pairs that may be used by the Access Control plugin. See <a href="#">47.4 DATATAG QoS Policy on page 787</a>.</p>
DataWriterProtocol	<p>This QoS Policy configures the <i>Connex</i>t on-the-network protocol, RTPS. See <a href="#">47.5 DATA_WRITER_PROTOCOL QoS Policy (DDS Extension) on page 788</a>.</p>
DataWriterResourceLimits	<p>Controls how many threads can concurrently block on a write() call of this <i>DataWriter</i>. See <a href="#">47.6 DATA_WRITER_RESOURCE_LIMITS QoS Policy (DDS Extension) on page 800</a>.</p>
Deadline	<p>For a <i>DataReader</i>, it specifies the maximum expected elapsed time between arriving DDS data samples.</p> <p>For a <i>DataWriter</i>, it specifies a commitment to publish DDS samples with no greater elapsed time between them.</p> <p>See <a href="#">47.7 DEADLINE QoS Policy on page 804</a>.</p>
DestinationOrder	<p>Controls how <i>Connex</i>t will deal with data sent by multiple <i>DataWriters</i> for the same topic. Can be set to "by reception timestamp" or to "by source timestamp". See <a href="#">47.8 DESTINATION_ORDER QoS Policy on page 806</a>.</p>
Durability	<p>Specifies whether or not <i>Connex</i>t will store and deliver data that were previously published to new <i>DataReaders</i>. See <a href="#">47.9 DURABILITY QoS Policy on page 809</a>.</p>
DurabilityService	<p>Various settings to configure the external <i>Persistence Service</i> used by <i>Connex</i>t for <i>DataWriters</i> with a Durability QoS setting of Persistent Durability. See <a href="#">47.10 DURABILITY SERVICE QoS Policy on page 814</a>.</p>
EntityName	<p>Assigns a name to a <i>DataWriter</i>. See <a href="#">47.11 ENTITY_NAME QoS Policy (DDS Extension) on page 817</a>.</p>
History	<p>Specifies how much data must to stored by <i>Connex</i>t for the <i>DataWriter</i> or <i>DataReader</i>. This QoS Policy affects the <a href="#">47.21 RELIABILITY QoS Policy on page 845</a> as well as the <a href="#">47.9 DURABILITY QoS Policy on page 809</a>. See <a href="#">47.12 HISTORY QoS Policy on page 818</a>.</p>
LatencyBudget	<p>Suggestion to <i>Connex</i>t on how much time is allowed to deliver data. See <a href="#">47.13 LATENCYBUDGET QoS Policy on page 823</a>.</p>
Lifespan	<p>Specifies how long <i>Connex</i>t should consider data sent by an user application to be valid. See <a href="#">47.14 LIFESPAN QoS Policy on page 824</a>.</p>
Liveliness	<p>Specifies and configures the mechanism that allows <i>DataReaders</i> to detect when <i>DataWriters</i> become disconnected or "dead." See <a href="#">47.15 LIVELINESS QoS Policy on page 825</a>.</p>

Table 31.16 DataWriter QoS Policies

QoS Policy	Description
MultiChannel	Configures a <i>DataWriter's</i> ability to send data on different multicast groups (addresses) based on the value of the data. See <a href="#">47.16 MULTI_CHANNEL QoS Policy (DDS Extension) on page 830</a> .
Ownership	Along with OwnershipStrength, specifies if <i>DataReaders</i> for a topic can receive data from multiple <i>DataWriters</i> at the same time. See <a href="#">47.17 OWNERSHIP QoS Policy on page 833</a> .
OwnershipStrength	Used to arbitrate among multiple <i>DataWriters</i> of the same instance of a Topic when Ownership QoS Policy is EXCLUSIVE. See <a href="#">47.18 OWNERSHIP_STRENGTH QoS Policy on page 836</a> .
Partition	Adds string identifiers that are used for matching <i>DataReaders</i> and <i>DataWriters</i> for the same Topic. See <a href="#">46.5 PARTITION QoS Policy on page 751</a> .
Property	Stores name/value (string) pairs that can be used to configure certain parameters of <i>Connex</i> that are not exposed through formal QoS policies. It can also be used to store and propagate application-specific name/value pairs, which can be retrieved by user code during discovery. See <a href="#">47.19 PROPERTY QoS Policy (DDS Extension) on page 837</a> .
PublishMode	Specifies how <i>Connex</i> sends application data on the network. By default, data is sent in the user thread that calls the <i>DataWriter's</i> <code>write()</code> operation. However, this QoS Policy can be used to tell <i>Connex</i> to use its own thread to send the data. See <a href="#">47.20 PUBLISH_MODE QoS Policy (DDS Extension) on page 843</a> .
Reliability	Specifies whether or not <i>Connex</i> will deliver data reliably. See <a href="#">47.21 RELIABILITY QoS Policy on page 845</a> .
ResourceLimits	Controls the amount of physical memory allocated for <i>Entities</i> , if dynamic allocations are allowed, and how they occur. Also controls memory usage among different instance values for keyed topics. See <a href="#">47.22 RESOURCE_LIMITS QoS Policy on page 850</a> .
Service	Intended for use by RTI infrastructure services. User applications should not modify its value. See <a href="#">47.23 SERVICE QoS Policy (DDS Extension) on page 853</a> .
TopicQueryDispatch	Configures the ability of a <i>DataWriter</i> to publish samples in response to a TopicQuery. See <a href="#">47.24 TOPIC_QUERY_DISPATCH QoS Policy (DDS Extension) on page 854</a> .
TransferMode	Configures the properties of a Zero Copy <i>DataWriter</i> . See <a href="#">47.25 TRANSFER_MODE QoS Policy on page 855</a> .
TransportPriority	Set by a <i>DataWriter</i> to tell <i>Connex</i> that the data being sent is a different "priority" than other data. See <a href="#">47.26 TRANSPORT_PRIORITY QoS Policy on page 856</a> .
TransportSelection	Allows you to select which physical transports a <i>DataWriter</i> or <i>DataReader</i> may use to send or receive its data. See <a href="#">47.27 TRANSPORT_SELECTION QoS Policy (DDS Extension) on page 858</a> .
TransportUnicast	Specifies a subset of transports and port number that can be used by an Entity to receive data. See <a href="#">47.28 TRANSPORT_UNICAST QoS Policy (DDS Extension) on page 859</a> .
TypeSupport	Used to attach application-specific value(s) to a <i>DataWriter</i> or <i>DataReader</i> . These values are passed to the serialization or deserialization routine of the associated data type. Also controls whether padding bytes are set to 0 during serialization. See <a href="#">47.29 TYPESUPPORT QoS Policy (DDS Extension) on page 863</a> .
UserData	Along with Topic Data QoS Policy and Group Data QoS Policy, used to attach a buffer of bytes to <i>Connex's</i> discovery meta-data. See <a href="#">47.30 USER_DATA QoS Policy on page 864</a> .
WriterDataLifeCycle	Controls how a <i>DataWriter</i> handles the lifecycle of the instances (keys) that the <i>DataWriter</i> is registered to manage. See <a href="#">47.31 WRITER_DATA_LIFECYCLE QoS Policy on page 866</a> .

Many of the *DataWriter* QoS Policies also apply to *DataReaders* (see [Chapter 40 DataReaders on page 615](#)). For a *DataWriter* to communicate with a *DataReader*, their QoS Policies must be compatible. Generally, for the QoS Policies that apply both to the *DataWriter* and the *DataReader*, the setting in the

*DataWriter* is considered an “offer” and the setting in the *DataReader* is a “request.” Compatibility means that what is offered by the *DataWriter* equals or surpasses what is requested by the *DataReader*. Each policy’s description includes compatibility restrictions. For more information on compatibility, see [42.1 QoS Requested vs. Offered Compatibility—the RxO Property on page 687](#).

Some of the policies may be changed after the *DataWriter* has been created. This allows the application to modify the behavior of the *DataWriter* while it is in use. To modify the QoS of an already-created *DataWriter*, use the `get_qos()` and `set_qos()` operations on the *DataWriter*. This is a general pattern for all *Entities*, described in [49.3 Changing the QoS for an Existing Entity on page 903](#).

## 31.15.1 Configuring QoS Settings when the DataWriter is Created

As described in [31.1 Creating DataWriters on page 393](#), there are different ways to create a *DataWriter*, depending on how you want to specify its QoS (with or without a QoS Profile).

- In [Figure 31.1: Creating a DataWriter with Default QoS Policies and a Listener on page 394](#), there is an example of how to create a *DataWriter* with default QoS Policies by using the special constant, `DDS_DATAWRITER_QOS_DEFAULT`, which indicates that the default QoS values for a *DataWriter* should be used. The default *DataWriter* QoS values are configured in the *Publisher* or *DomainParticipant*; you can change them with `set_default_datawriter_qos()` or `set_default_datawriter_qos_with_profile()`. Then any *DataWriters* created with the *Publisher* will use the new default values. As described in [Chapter 49 Configuring QoS Programmatically on page 900](#), this is a general pattern that applies to the construction of all *Entities*.
- To create a *DataWriter* with non-default QoS without using a QoS Profile, see the example code in [Figure 31.8: Creating a DataWriter with Modified QoS Policies \(not from a profile\) on the next page](#). It uses the *Publisher*’s `get_default_writer_qos()` method to initialize a `DDS_DataWriter-QoS` structure. Then the policies are modified from their default values before the structure is used in the `create_datawriter()` method.
- You can also create a *DataWriter* and specify its QoS settings via a QoS Profile. To do so, you will call `create_datawriter_with_profile()`, as seen in [Figure 31.9: Creating a DataWriter with a QoS Profile on the next page](#).
- If you want to use a QoS profile, but then make some changes to the QoS before creating the *DataWriter*, call `get_datawriter_qos_from_profile()` and `create_datawriter()` as seen in [Figure 31.10: Getting QoS Values from a Profile, Changing QoS Values, Creating a DataWriter with Modified QoS Values on the next page](#).

For more information, see [31.1 Creating DataWriters on page 393](#) and [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

### Notes:

- The examples in this section use the Traditional C++ API; for examples in the Modern C++ API, see the sections "DataWriter Use Cases," "QoS Use Cases," and "QoS Provider Use Cases" in the API Reference HTML documentation, under "Programming How-To's."
- In C, you must initialize the QoS structures before they are used, see [42.2 Special QoS Policy Handling Considerations for C on page 688](#).

**Figure 31.8: Creating a DataWriter with Modified QoS Policies (not from a profile)**

```
DDS_DataWriterQos writer_qos;
// initialize writer_qos with default values
publisher->get_default_datawriter_qos(writer_qos);
// make QoS changes
writer_qos.history.depth = 5;
// Create the writer with modified qos
DDSDataWriter * writer = publisher->create_datawriter(
    topic, writer_qos, NULL, DDS_STATUS_MASK_NONE);
if (writer == NULL) {
    // ... error
}
// narrow it for your specific data type
FooDataWriter* foo_writer = FooDataWriter::narrow(writer);
```

**Figure 31.9: Creating a DataWriter with a QoS Profile**

```
// Create the datawriter
DDSDataWriter * writer =
    publisher->create_datawriter_with_profile(
        topic, "MyWriterLibrary", "MyWriterProfile",
        NULL, DDS_STATUS_MASK_NONE);
if (writer == NULL) {
    // ... error
};
// narrow it for your specific data type
FooDataWriter* foo_writer = FooDataWriter::narrow(writer);
```

**Figure 31.10: Getting QoS Values from a Profile, Changing QoS Values, Creating a DataWriter with Modified QoS Values**

```
DDS_DataWriterQos writer_qos;
// Get writer QoS from profile
retcode = factory->get_datawriter_qos_from_profile(
    writer_qos, "WriterProfileLibrary", "WriterProfile");
if (retcode != DDS_RETCODE_OK) {
    // handle error
}
// Makes QoS changes
writer_qos.history.depth = 5;
DDSDataWriter * writer = publisher->create_datawriter(
    topic, writer_qos, NULL, DDS_STATUS_MASK_NONE);
if (participant == NULL) {
    // handle error
}
```

## 31.15.2 Comparing QoS Values

The `equals()` operation compares two *DataWriter*'s `DDS_DataWriterQoS` structures for equality. It takes two parameters for the two *DataWriter*'s QoS structures to be compared, then returns `TRUE` if they are equal (all values are the same) or `FALSE` if they are not equal.

## 31.15.3 Changing QoS Settings After the DataWriter Has Been Created

There are two ways to change an existing *DataWriter*'s QoS after it has been created—again depending on whether or not you are using a QoS Profile.

- To change QoS programmatically (that is, without using a QoS Profile), use `get_qos()` and `set_qos()`. See the example code in [Figure 31.11: Changing the QoS of an Existing DataWriter \(without a QoS Profile\) below](#). It retrieves the current values by calling the *DataWriter*'s `get_qos()` operation. Then it modifies the value and calls `set_qos()` to apply the new value. Note, however, that some QoS Policies cannot be changed after the *DataWriter* has been enabled—this restriction is noted in the descriptions of the individual QoS Policies.
- You can also change a *DataWriter*'s (and all other *Entities*'s) QoS by using a QoS Profile and calling `set_qos_with_profile()`. For an example, see [Figure 31.12: Changing the QoS of an Existing DataWriter with a QoS Profile below](#). For more information, see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

**Figure 31.11: Changing the QoS of an Existing DataWriter (without a QoS Profile)**

```
DDS_DataWriterQos writer_qos;
// Get current QoS.
if (datawriter->get_qos(writer_qos) != DDS_RETCODE_OK) {
    // handle error
}
// Makes QoS changes here
writer_qos.history.depth = 5;
// Set the new QoS
if (datawriter->set_qos(writer_qos) != DDS_RETCODE_OK ) {
    // handle error
}
```

### Note:

- In C, you must initialize the QoS structures before they are used, see [42.2 Special QoS Policy Handling Considerations for C on page 688](#).

**Figure 31.12: Changing the QoS of an Existing DataWriter with a QoS Profile**

```
retcode = writer->set_qos_with_profile(
    "WriterProfileLibrary", "WriterProfile");
if (retcode != DDS_RETCODE_OK) {
```

```
// handle error
}
```

## 31.15.4 Using a Topic's QoS to Initialize a DataWriter's QoS

Several *DataWriter* QoS Policies can also be found in the QoS Policies for *Topics* (see [18.1.3 Setting Topic QoS Policies on page 250](#)). The QoS Policies set in the Topic do not directly affect the *DataWriters* (or *DataReaders*) that use that *Topic*. In many ways, some QoS Policies are a *Topic*-level concept, even though the DDS standard allows you to set different values for those policies for different *DataWriters* and *DataReaders* of the same *Topic*. Thus, the policies in the **DDS\_TopicQos** structure exist as a way to help centralize and annotate the intended or suggested values of those QoS Policies. *Connex* does not check to see if the actual policies set for a *DataWriter* is aligned with those set in the *Topic* to which it is bound.

There are many ways to use the QoS Policies' values set in the *Topic* when setting the QoS Policies' values in a *DataWriter*. The most straightforward way is to get the values of policies directly from the *Topic* and use them in the policies for the *DataWriter*, as shown in [Figure 31.13: Copying Selected QoS from a Topic when Creating a DataWriter below](#).

**Figure 31.13: Copying Selected QoS from a Topic when Creating a DataWriter**

```
DDS_DataWriterQos writer_qos;
DDS_TopicQos topic_qos;
// topic and publisher already created
// get current QoS for the topic, default QoS for the writer
if (topic->get_qos(topic_qos) != DDS_RETCODE_OK) {
    // handle error
}
if (publisher->get_default_datawriter_qos(writer_qos)
    != DDS_RETCODE_OK) {
    // handle error
}
// Copy specific policies from topic QoS to writer QoS
writer_qos.deadline = topic_qos.deadline;
writer_qos.reliability = topic_qos.reliability;
// Create the DataWriter with the modified QoS
DDSDataWriter* writer = publisher->create_datawriter(topic,
    writer_qos, NULL, DDS_STATUS_MASK_NONE);
```

### Note:

- In C, you must initialize the QoS structures before they are used, see [42.2 Special QoS Policy Handling Considerations for C on page 688](#).

You can use the *Publisher*'s **copy\_from\_topic\_qos()** operation to copy all of the common policies from the *Topic* QoS to a *DataWriter* QoS. This is illustrated in [Figure 31.14: Copying all QoS from a Topic when Creating a DataWriter on the next page](#).

Figure 31.14: Copying all QoS from a Topic when Creating a DataWriter

```

DDS_DataWriterQos writer_qos;
DDS_TopicQos topic_qos;
// topic, publisher, writer_listener already created
if (topic->get_qos(topic_qos) != DDS_RETCODE_OK) {
// handle error
}
if (publisher->get_default_datawriter_qos(writer_qos)
    != DDS_RETCODE_OK)
{
// handle error
}
// copy relevant QoS from topic into writer's qos
publisher->copy_from_topic_qos(writer_qos, topic_qos);
// Optionally, modify policies as desired
writer_qos.deadline.duration.sec = 1;
writer_qos.deadline.duration.nanosec = 0;
// Create the DataWriter with the modified QoS
DDSDataWriter* writer = publisher->create_datawriter(topic,
    writer_qos, writer_listener, DDS_STATUS_MASK_ALL);

```

In another design pattern, you may want to start with the default QoS values for a *DataWriter* and override them with the QoS values of the *Topic*. [Figure 31.15: Combining Default Topic and DataWriter QoS \(Option 1\)](#) below gives an example of how to do this.

Because this is a common pattern, *Connex* provides a special macro, **DDS\_DATAWRITER\_QOS\_USE\_TOPIC\_QOS**, that can be used to indicate that the *DataWriter* should be created with the set of QoS values that results from modifying the default *DataWriter* QoS Policies with the QoS values specified by the *Topic*. [Figure 31.16: Combining Default Topic and DataWriter QoS \(Option 2\)](#) on the next page shows how the macro is used.

The code fragments shown in [Figure 31.15: Combining Default Topic and DataWriter QoS \(Option 1\)](#) below and [Figure 31.16: Combining Default Topic and DataWriter QoS \(Option 2\)](#) on the next page result in identical QoS settings for the created *DataWriter*.

**Note:**

- In C, you must initialize the QoS structures before they are used, see [42.2 Special QoS Policy Handling Considerations for C](#) on page 688.

Figure 31.15: Combining Default Topic and DataWriter QoS (Option 1)

```

DDS_DataWriterQos writer_qos;
DDS_TopicQos topic_qos;
// topic, publisher, writer_listener already created
if (topic->get_qos(topic_qos) != DDS_RETCODE_OK) {
// handle error

```

```

}
if (publisher->get_default_datawriter_qos(writer_qos)
    != DDS_RETCODE_OK) {
// handle error
}
if (publisher->copy_from_topic_qos(writer_qos, topic_qos)
    != DDS_RETCODE_OK) {
// handle error
}
// Create the DataWriter with the combined QoS
DDSDataWriter* writer =
    publisher->create_datawriter(topic, writer_qos,
        writer_listener, DDS_STATUS_MASK_ALL);

```

**Figure 31.16: Combining Default Topic and DataWriter QoS (Option 2)**

```

// topic, publisher, writer_listener already created
DDSDataWriter* writer = publisher->create_datawriter (topic,
DDS_DATAWRITER_QOS_USE_TOPIC_QOS,
writer_listener, DDS_STATUS_MASK_ALL);

```

For more information on the general use and manipulation of QoS Policies, see [Chapter 49 Configuring QoS Programmatically on page 900](#).

## 31.16 Navigating Relationships Among DDS Entities

### 31.16.1 Finding Matching Subscriptions

The following *DataWriter* operations can be used to get information on the *DataReaders* that are currently associated with the *DataWriter* (that is, the *DataReaders* to which *Connex* will send the data written by the *DataWriter*). A subscription consists of information about the *DataReader* and its associated *Subscriber* and *Topic*.

- **get\_matched\_subscriptions()**
- **get\_matched\_subscription\_data()**
- **get\_matched\_subscription\_locators()**

**get\_matched\_subscriptions()** will return a sequence of handles to matched *DataReaders*. You can use these handles in the **get\_matched\_subscription\_data()** method to get information about the *DataReader* such as the values of its QoS Policies, as well as information about its *Subscriber* and *Topic*.

**get\_matched\_subscription\_locators()** retrieves a list of locators for subscriptions currently "associated" with the *DataWriter*. Matched subscription locators include locators for all those subscriptions in the same DDS domain that have a matching Topic, compatible QoS, and a common partition that the *DomainParticipant* has not indicated should be "ignored." These are the locators that *Connex* uses to communicate with matching *DataReaders*. (See [24.1.1 Locator Format on page 327](#).)

**Note:** In the Modern C++ API, these operations are freestanding functions in the `dds::pub` or `rti::pub` namespaces.

You can also get the `DATA_WRITER_PROTOCOL_STATUS` for matching subscriptions with these operations (see [31.6.3 DATA\\_WRITER\\_PROTOCOL\\_STATUS on page 399](#)):

- `get_matched_subscription_datawriter_protocol_status()`
- `get_matched_subscription_datawriter_protocol_status_by_locator()`

**Notes:**

- The `get_matched_subscriptions()` function includes the return of handles of matched *DataReaders* that are no longer active. All of the handles returned by this function are valid inputs to the `get_matched_subscription_data()` function.
- Status/data for a matched subscription is kept even if the matched *DataReader* is not active. Status/data for a matched subscription will be removed only if the *DataReader* is gone: that is, the *DataReader* is destroyed and this change is propagated through a discovery update, or the *DataReader's DomainParticipant* is gone (either gracefully or its liveliness expired and *Connex* is configured to purge not-alive participants). Once a matched *DataReader* is gone, its status is deleted. If you try to get the status/data for a matched *DataReader* that is gone, the 'get status' or 'get data' call will return an error.
- If you want to know which matched *DataReaders* are not active, use `is_matched_subscription_active()`. See [Table 31.1 DataWriter Operations on page 390](#).
- *DataReaders* that have been ignored using the *DomainParticipant's ignore\_subscription()* operation are not considered to be matched even if the *DataReader* has the same *Topic* and compatible QoS Policies. Thus, they will not be included in the list of *DataReaders* returned by `get_matched_subscriptions()` or `get_matched_subscription_locators()`. See [27.2 Ignoring Publications and Subscriptions on page 354](#) for more on `ignore_subscription()`.
- The `get_matched_subscription_data()` operation does not retrieve the `type_code` information from built-in-topic data structures. This information is available through the `on_data_available()` callback (if a *DataReaderListener* is installed on the *SubscriptionBuiltinTopicDataReader*).

See also: [31.16.2 Finding the Matching Subscription's ParticipantBuiltinTopicData below](#)

## 31.16.2 Finding the Matching Subscription's ParticipantBuiltinTopicData

`get_matched_subscription_participant_data()` allows you to get the `DDS_ParticipantBuiltinTopicData` (see [Table 28.1 Participant Built-in Topic's Data Type \(DDS\\_ParticipantBuiltinTopicData\)](#)) of a matched subscription using a subscription handle.

This operation retrieves the information on a discovered *DomainParticipant* associated with the subscription that is currently matching with the *DataWriter*. The subscription handle passed into this operation must correspond to a subscription currently associated with the *DataWriter*. Otherwise, the operation will fail with `RETCODE_BAD_PARAMETER`. The operation may also fail with `RETCODE_PRECONDITION_NOT_MET` if the subscription corresponds to the same *DomainParticipant* to which the *DataWriter* belongs.

Use `get_matched_subscriptions()` (see [31.16.1 Finding Matching Subscriptions on page 442](#)) to find the subscriptions that are currently matched with the *DataWriter*.

### 31.16.3 Finding Related DDS Entities

These operations are useful for obtaining a handle to various related *Entities*:

- `get_publisher()`
- `get_topic()`

`get_publisher()` returns the *Publisher* that created the *DataWriter*. `get_topic()` returns the *Topic* with which the *DataWriter* is associated.

## 31.17 Asserting Liveliness

The `assert_liveliness()` operation can be used to manually assert the liveliness of the *DataWriter* without writing data. This operation is only useful if the kind of [47.15 LIVELINESS QoS Policy on page 825](#) is `MANUAL_BY_PARTICIPANT` or `MANUAL_BY_TOPIC`.

How *DataReaders* determine if *DataWriters* are alive is configured using the [47.15 LIVELINESS QoS Policy on page 825](#). The `lease_duration` parameter of the LIVELINESS QoS Policy is a contract by the *DataWriter* to all of its matched *DataReaders* that it will send a packet within the time value of the `lease_duration` to state that it is still alive.

There are three ways to assert liveliness. One is to have *Connex* itself send liveliness packets periodically when the kind of LIVELINESS QoS Policy is set to `AUTOMATIC`. The other two ways to assert liveliness, used when liveliness is set to `MANUAL`, are to call `write()` to send data or to call the `assert_liveliness()` operation without sending data.

## 31.18 Turbo Mode and Automatic Throttling for DataWriter Performance—Experimental Features

This section describes two experimental features. The *DataWriter* has many QoS settings that can affect the latency and throughput of outgoing data. There are QoS settings to control send window size (see [32.4.2.1 Understanding the Send Queue and Setting its Size on page 455](#)) and settings that allow to aggregate multiple DDS samples together to reduce CPU and bandwidth utilization (see [47.2](#)

[BATCH QoSPolicy \(DDS Extension\) on page 773](#) and [34.4 FlowControllers \(DDS Extension\) on page 532](#)). The choice of settings that provide the best performance depends on several factors, such as the frequency of writing data, the size of the data, or the condition of the network. If these factors do not change over time, you can choose values for those QoS settings that best suit your system. If these factors do change over time in your system, you can use the following properties to let *Connex* automatically adjust the QoS settings as system conditions change:

- **dds.domain\_participant.auto\_throttle.enable**: Configures the *DomainParticipant* to gather internal measurements (during *DomainParticipant* creation) that are required for the Auto Throttle feature. This allows *DataWriters* belonging to this *DomainParticipant* to use the Auto Throttle feature. Default: false.
- **dds.data\_writer.auto\_throttle.enable**: Enables automatic throttling in the *DataWriter* so it can automatically adjust the writing rate and the send window size; this minimizes the need for repair DDS samples and improves latency. Default: false. For additional information on automatic throttling, see [47.2.4 Turbo Mode: Automatically Adjusting the Number of Bytes in a Batch—Experimental Feature on page 776](#).

**Note:** This property takes effect only in *DataWriters* that belong to a *DomainParticipant* that has set the property **dds.domain\_participant.auto\_throttle.enable** (described above) to true.

- **dds.data\_writer.enable\_turbo\_mode**: Enables Turbo Mode and adjusts the batch [max\\_data\\_bytes on page 774](#) (see [47.2 BATCH QoSPolicy \(DDS Extension\) on page 773](#)) based on how frequently the *DataWriter* writes data. Default: false. For additional information, see [47.2.4 Turbo Mode: Automatically Adjusting the Number of Bytes in a Batch—Experimental Feature on page 776](#).

The Built-in QoS profile **BuiltinQoSLibExp::Generic.AutoTuning** enables both Turbo Mode and Auto Throttling.

# Chapter 32 Reliability Models for Sending Data

The DCPS reliability model recognizes that the optimal balance between time-determinism and data-delivery reliability varies widely among applications and can vary among different publications within the same application. For example, individual DDS samples of *signal* data can often be dropped because their value disappears when the next DDS sample is sent. However, each DDS sample of *command* data must be received and it must be received in the order sent.

The QosPolicies provide a way to customize the determinism/reliability trade-off on a per *Topic* basis, or even on a per *DataWriter/DataReader* basis.

There are two delivery models:

- Best-effort delivery model: “I’m not concerned about missed or unordered DDS samples.”
- Reliable delivery model: “Make sure all DDS samples get there, in order.”

*Connex* uses *best-effort* delivery by default. The other type of delivery that *Connex* supports is called *reliable*. This chapter provides instructions on how to set up and use reliable communication.

## 32.1 Best-effort Delivery Model

By default, *Connex* uses the best-effort delivery model: there is no effort spent ensuring in-order delivery or resending lost DDS samples. Best-effort *DataReaders* ignore lost DDS samples in favor of the latest DDS sample. Your application is only notified if it does not receive a new DDS sample within a certain time period (set in the [47.7 DEADLINE QosPolicy on page 804](#)).

The best-effort delivery model is best for time-critical information that is sent continuously. For instance, consider a *DataWriter* for the value of a sensor device (such as a the pressure inside a tank), and assume the *DataWriter* sends DDS samples continuously. In this situation, a

*DataReader* for this *Topic* is only interested in having the latest pressure reading available—older DDS samples are obsolete.

## 32.2 Reliable Delivery Model

Reliable delivery means the DDS samples are guaranteed to arrive, in the order published.

The *DataWriter* maintains a *send queue* with space to hold the last  $X$  number of DDS samples sent. Similarly, a *DataReader* maintains a *receive queue* with space for consecutive  $X$  expected DDS samples.

The *send* and *receive queues* are used to temporarily cache DDS samples until *Connex*t is sure the DDS samples have been delivered and are not needed anymore. *Connex*t removes DDS samples from a publication's *send queue* after the DDS sample has been acknowledged by all reliable subscriptions. When positive acknowledgements are disabled (see [47.5 DATA\\_WRITER\\_PROTOCOL QoS Policy \(DDS Extension\) on page 788](#) and [48.1 DATA\\_READER\\_PROTOCOL QoS Policy \(DDS Extension\) on page 871](#)), DDS samples are removed from the send queue after the corresponding keep-duration has elapsed (see [Table 47.14 DDS\\_RtpsReliableWriterProtocol\\_t](#)).

If an out-of-order DDS sample arrives, *Connex*t speculatively caches it in the *DataReader*'s *receive queue* (provided there is space in the queue). Only consecutive DDS samples are passed on to the *DataReader*.

*DataWriters* can be set up to wait for available queue space when sending DDS samples. This will cause the sending thread to block until there is space in the *send queue*. (Or, you can decide to sacrifice sending DDS samples reliably so that the sending rate is not compromised.) If the *DataWriter* is set up to ignore the full queue and sends anyway, then older cached DDS samples will be pushed out of the queue before all *DataReaders* have received them. In this case, the *DataReader* (or its *Subscriber*) is notified of the missing DDS samples through its *Listener* and/or *Conditions*.

*Connex*t automatically sends acknowledgments (ACKNACKs) as necessary to maintain reliable communications. The *DataWriter* may choose to block for a specified duration to wait for these acknowledgments (see [31.11 Waiting for Acknowledgments in a DataWriter on page 417](#)).

*Connex*t establishes a virtual reliable channel between the matching *DataWriter* and all *DataReaders*. This mechanism isolates *DataReaders* from each other, allows the application to control memory usage, and provides mechanisms for the *DataWriter* to balance reliability and determinism. Moreover, the use of *send* and *receive queues* allows *Connex*t to be implemented efficiently without introducing unnecessary delays in the stream.

Note that a successful return code (DDS\_RETCODE\_OK) from `write()` does not necessarily mean that all *DataReaders* have received the data. It only means that the DDS sample has been added to the *DataWriter*'s queue. To see if all *DataReaders* have received the data, look at the [31.6.8 RELIABLE\\_WRITER\\_CACHE\\_CHANGED Status \(DDS Extension\) on page 406](#) to see if any DDS samples are unacknowledged.

Suppose *DataWriter* A reliably publishes a *Topic* to which *DataReaders* B and C reliably subscribe. B has space in its queue, but C does not. Will *DataWriter* A be notified? Will *DataReader* C receive any error messages or callbacks? The exact behavior depends on the QoS settings:

- If `HISTORY_KEEP_ALL` is specified for C, C will reject DDS samples that cannot be put into the queue and request A to resend missing DDS samples. The *Listener* is notified with the `on_sample_rejected()` callback (see [40.7.8 SAMPLE\\_REJECTED Status on page 640](#)). If A has a queue large enough, or A is no longer writing new DDS samples, A won't notice unless it checks the [31.6.8 RELIABLE\\_WRITER\\_CACHE\\_CHANGED Status \(DDS Extension\) on page 406](#).
- If `HISTORY_KEEP_LAST` is specified for C, C will drop old DDS samples and accept new ones. To A, it is as if all DDS samples have been received by C (that is, they have all been acknowledged).

## 32.3 Overview of the Reliable Protocol

An important advantage of *Connex* is that it can offer the reliability and other QoS guarantees mandated by DDS on top of a very wide variety of transports, including packet-based transports, unreliable networks, multicast-capable transports, bursty or high-latency transports, etc. *Connex* is also capable of maintaining liveliness and application-level QoS even in the presence of sporadic connectivity loss at the transport level, an important benefit in mobile networks. *Connex* accomplishes this by implementing a reliable protocol that sequences and acknowledges application-level messages and monitors the liveliness of the link. This is called the Real-Time Publish-Subscribe (RTPS) protocol; it is an open, international standard.<sup>1</sup>

In order to work in this wide range of environments, the reliable protocol defined by RTPS is highly configurable with a set of parameters that let the application fine-tune its behavior to trade-off latency, responsiveness, liveliness, throughput, and resource utilization. This section describes the most important features to the extent needed to understand how the configuration parameters affect its operation.

The most important features of the RTPS protocol are:

- Support for both push and pull operating modes
- Support for both positive and negative acknowledgments
- Support for high data-rate *DataWriters*
- Support for multicast *DataReaders*
- Support for high-latency environments

In order to support these features, RTPS uses several types of messages: Data messages (DATA), acknowledgments (ACKNACKs), and heartbeats (HBs).

---

<sup>1</sup>For a link to the RTPS specification, see the RTI website, [www.rti.com](http://www.rti.com).

- **DATA** messages contain snapshots of the value of data-objects and associate the snapshot with a sequence number that *Connex* uses to identify them within the *DataWriter*'s history. These snapshots are stored in the history as a direct result of the application calling **write()** on the *DataWriter*. Incremental sequence numbers are automatically assigned by the *DataWriter* each time **write()** is called. In [Figure 32.1: Basic RTPS Reliable Protocol on the next page](#) through [32.4 Using QosPolicies to Tune the Reliable Protocol on page 452](#), these messages are represented using the notation DATA(<value>, <sequenceNum>). For example, DATA(A,1) represents a message that communicates the value 'A' and associates the sequence number '1' with this message. A DATA is used for both keyed and non-keyed data types.
- **HB** messages announce to the *DataReader* that it should have received all snapshots up to the one tagged with a range of sequence numbers and can also request the *DataReader* to send an acknowledgement back. For example, HB(1-3) indicates to the *DataReader* that it should have received snapshots tagged with sequence numbers 1, 2, and 3 and asks the *DataReader* to confirm this.
- **ACKNACK** messages communicate to the *DataWriter* that particular snapshots have been successfully stored in the *DataReader*'s history. ACKNACKs also tell the *DataWriter* which snapshots are missing on the *DataReader* side. The ACKNACK message includes a set of sequence numbers represented as a bit map. The sequence numbers indicate which ones the *DataReader* is missing. (The bit map contains the base sequence number that has not been received, followed by the number of bits in bit map and the optional bit map. The maximum size of the bit map is 256.) All numbers up to (not including) those in the set are considered positively acknowledged. They are represented in [Figure 32.1: Basic RTPS Reliable Protocol on the next page](#) through [Figure 32.7: Use of heartbeat\\_period on page 464](#) as ACKNACK(<first-missing>) or ACKNACK(<first-missing>-<last-missing>). For example, ACKNACK(4) indicates that the snapshots with sequence numbers 1, 2, and 3 have been successfully stored in the *DataReader* history, and that 4 has not been received.

It is important to note that *Connex* can bundle multiple of the above messages within a single network packet. This 'submessage bundling' provides for higher performance communications.

It is also worth noting that because HB and ACKNACK messages communicate the state of reliable communication between individual writer and reader pairs, *Connex* requires at least one unicast destination so that these messages can be sent to the correct destinations, as opposed to being broadcast over a multicast destination. *Connex* does support enabling sending periodic heartbeats to a multicast destination using the **enable\_multicast\_periodic\_heartbeat** in the [44.9 WIRE\\_PROTOCOL QosPolicy \(DDS Extension\) on page 730](#).

Figure 32.1: Basic RTPS Reliable Protocol

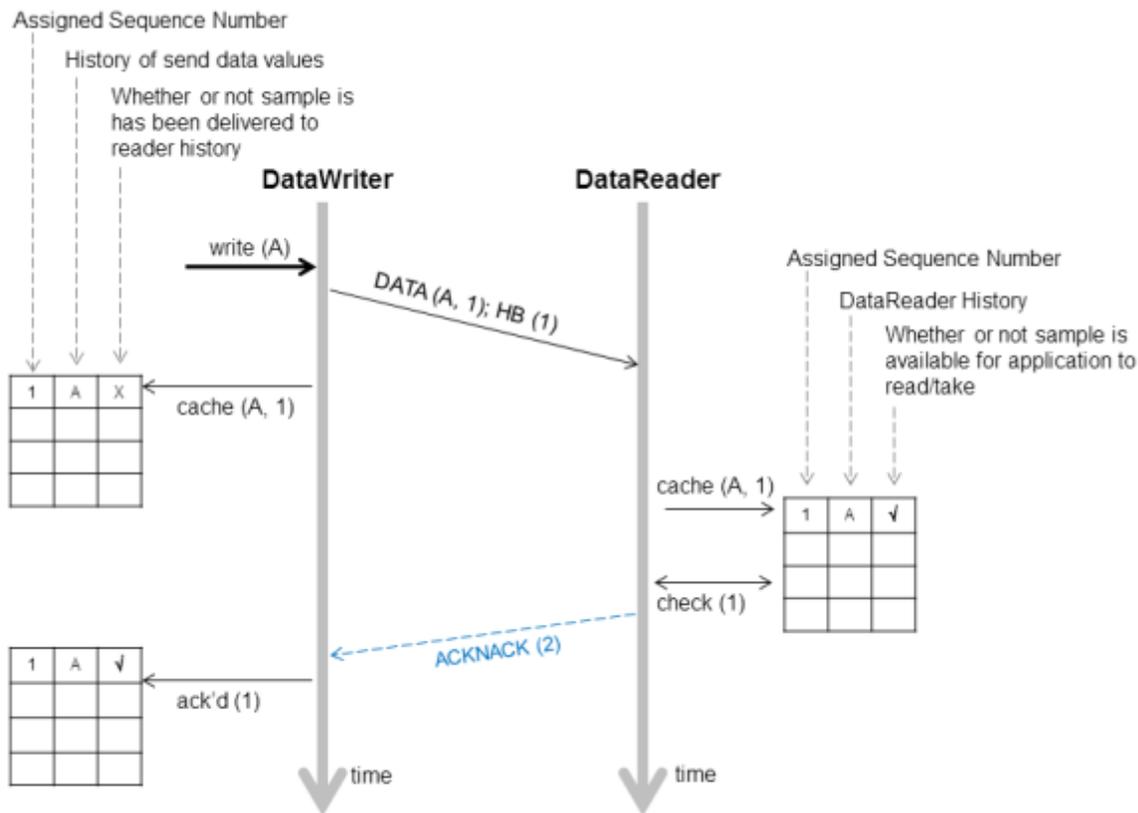

Figure 32.1: Basic RTPS Reliable Protocol above illustrates the basic behavior of the protocol when an application calls the `write()` operation on a *DataWriter* that is associated with a *DataReader*. As mentioned, the RTPS protocol can bundle multiple submessages into a single network packet. In Figure 32.1: Basic RTPS Reliable Protocol above this feature is used to piggyback a HB message to the DATA message. Note that before the message is sent, the data is given a sequence number (1 in this case) which is stored in the *DataWriter*'s send queue. As soon as the message is received by the *DataReader*, it places it into the *DataReader*'s receive queue. From the sequence number the *DataReader* can tell that it has not missed any messages and therefore it can make the data available immediately to the user (and call the *DataReaderListener*). This is indicated by the “✓” symbol. The reception of the HB(1) causes the *DataReader* to check that it has indeed received all updates up to and including the one with `sequenceNumber=1`. Since this is true, it replies with an `ACKNACK(2)` to positively acknowledge all messages up to (but not including) sequence number 2. The *DataWriter* notes that the update has been acknowledged, so it no longer needs to be retained in its send queue. This is indicated by the “✓” symbol.

Figure 32.2: RTPS Reliable Protocol in the Presence of Message Loss

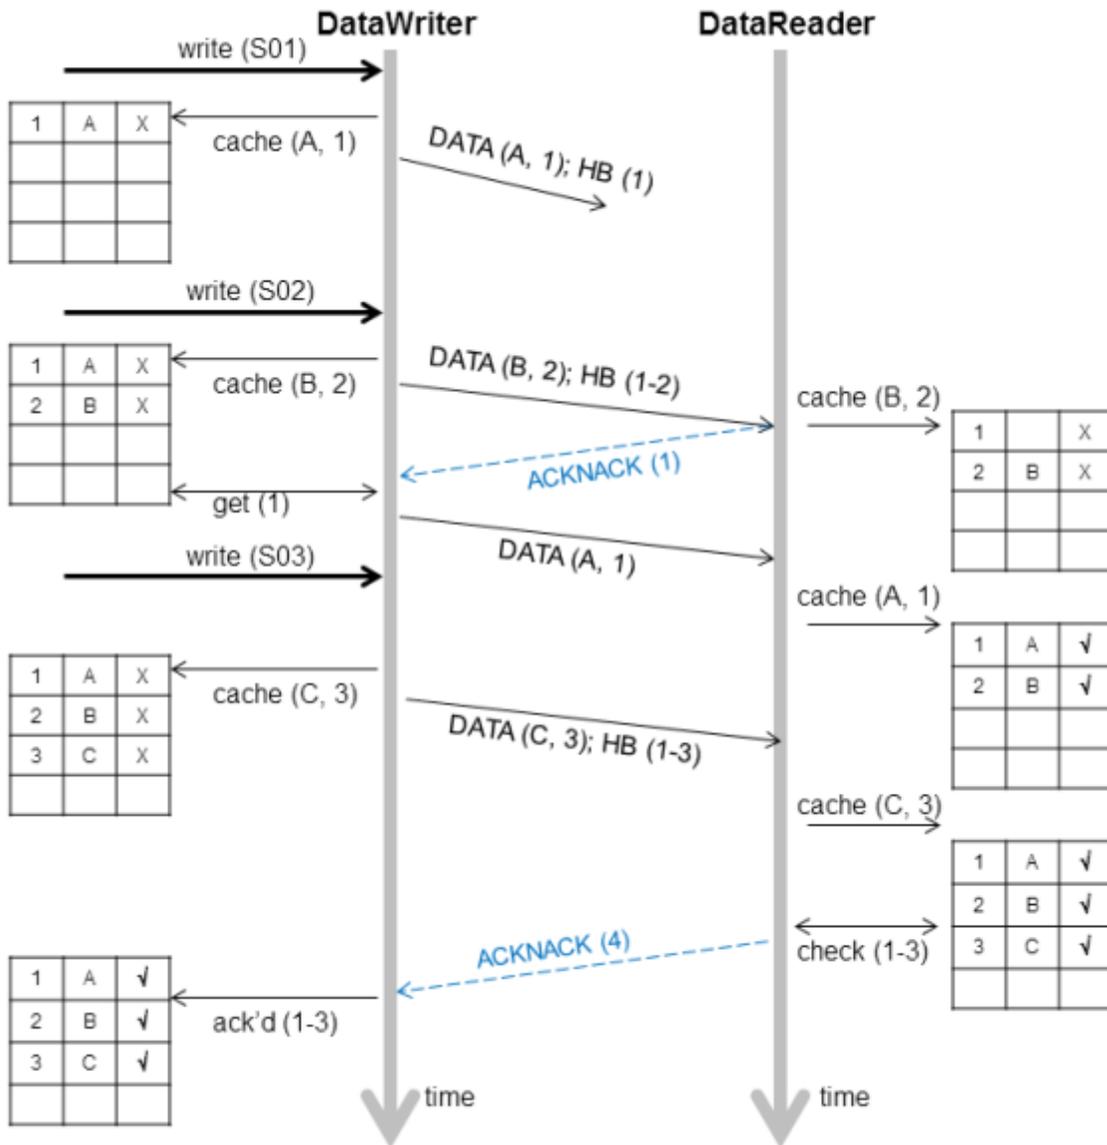

Figure 32.2: RTPS Reliable Protocol in the Presence of Message Loss above illustrates the behavior of the protocol in the presence of lost messages. Assume that the message containing DATA(A,1) is dropped by the network. When the *DataReader* receives the next message (DATA(B,2); HB(1-2)) the *DataReader* will notice that the data associated with sequence number 1 was never received. It realizes this because the heartbeat HB(1-2) tells the *DataReader* that it should have received all messages up to and including the one with sequence number 2. This realization has two consequences:

- The data associated with sequence number 2 (B) is tagged with 'X' to indicate that it is not deliverable to the application (that is, it should not be made available to the application, because the

application needs to receive the data associated with DDS sample 1 (A) first).

- An ACKNACK(1) is sent to the *DataWriter* to request that the data tagged with sequence number 1 be resent.

Reception of the ACKNACK(1) causes the *DataWriter* to resend DATA(A,1). Once the *DataReader* receives it, it can ‘commit’ both A and B such that the application can now access both (indicated by the “✓”) and call the *DataReaderListener*. From there on, the protocol proceeds as before for the next data message (C) and so forth.

A subtle but important feature of the RTPS protocol is that ACKNACK messages are only sent as a direct response to HB messages. This allows the *DataWriter* to better control the overhead of these ‘administrative’ messages. For example, if the *DataWriter* knows that it is about to send a chain of DATA messages, it can bundle them all and include a single HB at the end, which minimizes ACKNACK traffic.

## 32.4 Using QoS Policies to Tune the Reliable Protocol

Reliability is controlled by the QoS Policies in [Table 32.1 QoS Policies for Reliable Communications](#). To enable reliable delivery, read the following sections to learn how to change the QoS for the *DataWriter* and *DataReader*:

- [32.4.1 Enabling Reliability on the next page](#)
- [32.4.2 Tuning Queue Sizes and Other Resource Limits on page 454](#)
- [32.4.4 Controlling Heartbeats and Retries with DataWriterProtocol QoS Policy on page 462](#)
- [32.4.5 Avoiding Message Storms with DataReaderProtocol QoS Policy on page 470](#)
- [32.4.6 Resending DDS Samples to Late-Joiners with the Durability QoS Policy on page 470](#)

Then see [32.4.7 Use Cases on page 470](#) to explore example use cases:

Table 32.1 QoS Policies for Reliable Communications

QoS Policy	Description	Related Entities <sup>1</sup>	Reference
Reliability	To establish reliable communication, this QoS must be set to <b>DDS_RELIABLE_RELIABILITY_QOS</b> for the <i>DataWriter</i> and its <i>DataReaders</i> .	DW, DR	<a href="#">32.4.1 Enabling Reliability below, 47.21 RELIABILITY QoS Policy on page 845</a>
ResourceLimits	This QoS determines the amount of resources each side can use to manage instances and DDS samples of instances. Therefore it controls the size of the <i>DataWriter's</i> send queue and the <i>DataReader's</i> receive queue. The send queue stores DDS samples until they have been ACKed by all <i>DataReaders</i> . The <i>DataReader's</i> receive queue stores DDS samples for the user's application to access.	DW, DR	<a href="#">32.4.2 Tuning Queue Sizes and Other Resource Limits on the next page, 47.22 RESOURCE_LIMITS QoS Policy on page 850</a>
History	This QoS affects how a <i>DataWriter/DataReader</i> behaves when its send/receive queue fills up.	DW, DR	<a href="#">32.4.3 Controlling Queue Depth with the History QoS Policy on page 461, 47.12 HISTORY QoS Policy on page 818</a>
DataWriterProtocol	This QoS configures <i>DataWriter</i> -specific protocol. The QoS can disable positive ACKs for its <i>DataReaders</i> .	DW	<a href="#">32.4.4 Controlling Heartbeats and Retries with DataWriter-Protocol QoS Policy on page 462, 47.5 DATA_WRITER_PROTOCOL QoS Policy (DDS Extension) on page 788</a>
DataReaderProtocol	When a reliable <i>DataReader</i> receives a heartbeat from a <i>DataWriter</i> and needs to return an ACKNACK, the <i>DataReader</i> can choose to delay a while. This QoS sets the minimum and maximum delay. It can also disable positive ACKs for the <i>DataReader</i> .	DR	<a href="#">32.4.5 Avoiding Message Storms with DataReader-Protocol QoS Policy on page 470, 48.1 DATA_READER_PROTOCOL QoS Policy (DDS Extension) on page 871</a>
DataReaderResourceLimits	This QoS determines additional amounts of resources that the <i>DataReader</i> can use to manage DDS samples (namely, the size of the <i>DataReader's</i> internal queues, which cache DDS samples until they are ordered for reliability and can be moved to the <i>DataReader's</i> receive queue for access by the user's application).	DR	<a href="#">32.4.2 Tuning Queue Sizes and Other Resource Limits on the next page, 48.2 DATA_READER_RESOURCE_LIMITS QoS Policy (DDS Extension) on page 876</a>
Durability	This QoS affects whether late-joining <i>DataReaders</i> will receive all previously-sent data or not.	DW, DR	<a href="#">32.4.6 Resending DDS Samples to Late-Joiners with the Durability QoS Policy on page 470, 47.9 DURABILITY QoS Policy on page 809</a>

## 32.4.1 Enabling Reliability

You must modify the [47.21 RELIABILITY QoS Policy on page 845](#) of the *DataWriter* and each of its reliable *DataReaders*. Set the **kind** field to `DDS_RELIABLE_RELIABILITY_QOS`:

<sup>1</sup>DW = DataWriter, DR = DataReader

- *DataWriter*

```
writer_qos.reliability.kind = DDS_RELIABLE_RELIABILITY_QOS;
```

- *DataReader*

```
reader_qos.reliability.kind = DDS_RELIABLE_RELIABILITY_QOS;
```

### 32.4.1.1 Blocking until the Send Queue Has Space Available

The **max\_blocking\_time** property in the [47.21 RELIABILITY QosPolicy on page 845](#) indicates how long a *DataWriter* can be blocked during a **write()**.

If **max\_blocking\_time** is non-zero and the reliability send queue is full, the write is blocked (the DDS sample is not sent). If **max\_blocking\_time** has passed and the DDS sample is still *not* sent, **write()** returns `DDS_RETCODE_TIMEOUT` and the DDS sample is not sent.

If the number of unacknowledged DDS samples in the reliability send queue drops below **max\_samples** (set in the [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#)) before **max\_blocking\_time**, the DDS sample is sent and **write()** returns `DDS_RETCODE_OK`.

If **max\_blocking\_time** is zero and the reliability send queue is full, **write()** returns `DDS_RETCODE_TIMEOUT` and the DDS sample is not sent.

## 32.4.2 Tuning Queue Sizes and Other Resource Limits

Set the [47.12 HISTORY QosPolicy on page 818](#) appropriately to accommodate however many DDS samples should be saved in the *DataWriter*'s send queue or in the *DataReader*'s receive queue.

Set the size of the send window in the `DDS_RtpsReliableWriterProtocol_t` policy (in the [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 788](#)) appropriately to accommodate the maximum number of unacknowledged DDS samples that can be queued at a time from a *DataWriter*.

For more information, see the following sections:

- [32.4.2.1 Understanding the Send Queue and Setting its Size on the next page](#)
- [32.4.2.2 Understanding the Receive Queue and Setting Its Size on page 459](#)
- [47.5.4 Configuring the Send Window Size on page 796](#)

**Note:** The `HistoryQosPolicy`'s **depth** must be less than or equal to the `ResourceLimitsQosPolicy`'s **max\_samples\_per\_instance**; **max\_samples\_per\_instance** must be less than or equal to the `ResourceLimitsQosPolicy`'s **max\_samples** (see [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#)), and **max\_samples\_per\_remote\_writer** (see [48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 876](#)) must be less than or equal to **max\_samples**.

- `depth <= max_samples_per_instance <= max_samples`
- `max_samples_per_remote_writer <= max_samples`

### Examples:

#### *DataWriter*

```
writer_qos.resource_limits.initial_instances = 10;
writer_qos.resource_limits.initial_samples = 200;
writer_qos.resource_limits.max_instances = 100;
writer_qos.resource_limits.max_samples = 2000;
writer_qos.resource_limits.max_samples_per_instance = 20;
writer_qos.history.depth = 20;
```

#### *DataReader*

```
reader_qos.resource_limits.initial_instances = 10;
reader_qos.resource_limits.initial_samples = 200;
reader_qos.resource_limits.max_instances = 100;
reader_qos.resource_limits.max_samples = 2000;
reader_qos.resource_limits.max_samples_per_instance = 20;
reader_qos.history.depth = 20;
reader_qos.reader_resource_limits.max_samples_per_remote_writer = 20;
```

### 32.4.2.1 Understanding the Send Queue and Setting its Size

A *DataWriter*'s send queue is used to store each DDS sample it writes. A DDS sample will be removed from the send queue after it has been acknowledged (through an ACKNACK) by all the reliable *DataReaders*. A *DataReader* can request that the *DataWriter* resend a missing DDS sample (through an ACKNACK). If that DDS sample is still available in the send queue, it will be resent. To elicit timely ACKNACKs, the *DataWriter* will regularly send heartbeats to its reliable *DataReaders*.

A *DataWriter*'s send queue size is determined by its [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#), specifically the `max_samples` field. The appropriate value depends on application parameters such as how fast the publication calls `write()`.

A *DataWriter* has a "send window" that is the maximum number of unacknowledged DDS samples allowed in the send queue before a *DataWriter* will start blocking during the `write()` call (see [31.8.1 Blocking During a write\(\) on page 412](#)). The send window enables throttling of the publishing application to avoid overwhelming matched *DataReaders*. If the *DataReaders* are not acknowledging samples fast enough and the *DataWriter*'s send window fills up, the *DataWriter* will be slowed down because each `write()` call will block until the unacknowledged sample count in the send window decreases.

The size of the send window is determined by the `DataWriterProtocolQosPolicy`, specifically the fields `min_send_window_size` and `max_send_window_size` within the `rtps_reliable_writer` field of type `DDS_RtpsReliableWriterProtocol_t`. Other fields can be used to configure a variable-sized send window, where the send window size changes in response to network congestion to maximize the effective send rate. Like for `max_samples`, the appropriate values depend on application parameters. For more

information on configuring the send window size, refer to [47.5.4 Configuring the Send Window Size on page 796](#).

**Strict reliability:** If a *DataWriter* does not receive ACKNACKs from one or more reliable *DataReaders*, it is possible for the reliability send queue—either its finite `max_send_window_size` or its effective `max_send_window_size` if `max_send_window_size` is infinite—to fill up. Effective `max_send_window_size` is defined as either `max_samples` (if batching is not used) or `max_batches` (if batching is used). If you want to achieve strict reliability, the `kind` field in the [47.12 HISTORY QosPolicy on page 818](#) for both the *DataReader* and *DataWriter* must be set to `KEEP_ALL`, positive acknowledgments must be enabled for both the *DataReader* and *DataWriter*, and your publishing application should wait until space is available in the reliability queue before writing any more DDS samples. *Connex* provides two mechanisms to do this:

- Allow the `write()` operation to block until there is space in the reliability queue again to store the DDS sample. The maximum time this call blocks is determined by the `max_blocking_time` field in the [47.21 RELIABILITY QosPolicy on page 845](#) (also discussed in [32.4.1.1 Blocking until the Send Queue Has Space Available on page 454](#)).
- Use the *DataWriter*'s *Listener* to be notified when the reliability queue fills up or empties again.

When the [47.12 HISTORY QosPolicy on page 818](#) on the *DataWriter* is set to `KEEP_LAST`, strict reliability is not guaranteed. When there are `depth` number of DDS samples in the queue (set in the [47.12 HISTORY QosPolicy on page 818](#), see [32.4.3 Controlling Queue Depth with the History QosPolicy on page 461](#)) the oldest DDS sample will be dropped from the queue when a new DDS sample is written. *Note that in such a reliable mode, when the send window is larger than `max_samples` (or `max_batches` if batching is enabled), the *DataWriter* will never block, but strict reliability is no longer guaranteed.* If there is a request for the purged DDS sample from any *DataReaders*, the *DataWriter* will send a heartbeat that no longer contains the sequence number of the dropped DDS sample (it will not be able to send the DDS sample).

Alternatively, a *DataWriter* with `KEEP_LAST` may block on `write()` when its send window is smaller than its send queue. The *DataWriter* will block when its send window is full. After the blocking time has elapsed, the *DataWriter* may replace a DDS sample, regardless of its acknowledgement status. See [31.8.2 write\(\) behavior with KEEP\\_LAST and KEEP\\_ALL on page 413](#) for a detailed explanation of what happens when certain limits are reached during a call to `write()`.

The send queue size is set in the `max_samples` field of the [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#). The appropriate size for the send queue depends on application parameters (such as the send rate), channel parameters (such as end-to-end delay and probability of packet loss), and quality of service requirements (such as maximum acceptable probability of DDS sample loss).

The *DataReader*'s receive queue size should generally be larger than the *DataWriter*'s send queue size. Receive queue size is discussed in [32.4.2.2 Understanding the Receive Queue and Setting Its Size on page 459](#).

A good rule of thumb, based on a simple model that assumes individual packet drops are not correlated and time-independent, is that the size of the reliability send queue,  $N$ , is as shown in [Figure 32.3: Calculating Minimum Send Queue Size for a Desired Level of Reliability](#) below.

**Figure 32.3: Calculating Minimum Send Queue Size for a Desired Level of Reliability**

$$N = 2RT(\log(1-Q))/\log(p)$$

*Simple formula for determining the minimum size of the send queue required for strict reliability*

In the above equation,  $R$  is the rate of sending DDS samples,  $T$  is the round-trip transmission time,  $p$  is the probability of a packet loss in a round trip, and  $Q$  is the required probability that a DDS sample is eventually successfully delivered. Of course, network-transport dropouts must also be taken into account and may influence or dominate this calculation.

[Table 32.2 Required Size of the Send Queue for Different Network Parameters](#) gives the required size of the send queue for several common scenarios.

**Table 32.2 Required Size of the Send Queue for Different Network Parameters**

$Q^1$	$p^2$	$T^3$	$R^4$	$N^5$
99%	1%	0.001 <sup>6</sup> sec	100 Hz	1
99%	1%	0.001 sec	2000 Hz	2
99%	5%	0.001 sec	100 Hz	1
99%	5%	0.001 sec	2000 Hz	4
99.99%	1%	0.001 sec	100 Hz	1
99.99%	1%	0.001 sec	2000 Hz	6
99.99%	5%	0.001 sec	100 Hz	1
99.99%	5%	0.001 sec	2000 Hz	8

**Note:** Packet loss on a network frequently happens in bursts, and the packet loss events are correlated. This means that the probability of a packet being lost is much higher if the previous packet was lost because it indicates a congested network or busy receiver. For this situation, it may be better to use a queue size that can accommodate the longest period of network congestion, as illustrated in [Figure 32.4: Calculating Minimum Send Queue Size for Networks with Dropouts below](#).

**Figure 32.4: Calculating Minimum Send Queue Size for Networks with Dropouts**

$$N = RD(Q)$$

*Send queue size as a function of send rate "R" and maximum dropout time D*

In the above equation R is the rate of sending DDS samples, D(Q) is a time such that Q percent of the dropouts are of equal or lesser length, and Q is the required probability that a DDS sample is eventually successfully delivered. The problem with the above formula is that it is hard to determine the value of D(Q) for different values of Q.

<sup>1</sup>"Q" is the desired level of reliability measured as the probability that any data update will eventually be delivered successfully. In other words, percentage of DDS samples that will be successfully delivered.

<sup>2</sup>"p" is the probability that any single packet gets lost in the network.

<sup>3</sup>"T" is the round-trip transport delay in the network

<sup>4</sup>"R" is the rate at which the publisher is sending updates.

<sup>5</sup>"N" is the minimum required size of the send queue to accomplish the desired level of reliability "Q".

<sup>6</sup>The typical round-trip delay for a dedicated 100 Mbit/second ethernet is about 0.001 seconds.

For example, if we want to ensure that 99.9% of the DDS samples are eventually delivered successfully, and we know that the 99.9% of the network dropouts are shorter than 0.1 seconds, then we would use  $N = 0.1 * R$ . So for a rate of 100Hz, we would use a send queue of  $N = 10$ ; for a rate of 2000Hz, we would use  $N = 200$ .

### 32.4.2.2 Understanding the Receive Queue and Setting Its Size

DDS samples are stored in the *DataReader's* receive queue, which is accessible to the user's application.

A DDS sample is removed from the receive queue after it has been accessed by `take()`, as described in [41.3 Accessing DDS Data Samples with Read or Take on page 665](#). Note that `read()` does not remove DDS samples from the queue.

A *DataReader's* receive queue size is limited by its [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#), specifically the `max_samples` field. The storage of out-of-order DDS samples for each *DataWriter* is also allocated from the *DataReader's* receive queue; this DDS sample resource is shared among all reliable *DataWriters*. That is, **`max_samples`** includes both ordered and out-of-order DDS samples.

A *DataReader* can maintain reliable communications with multiple *DataWriters* (e.g., in the case of the [47.18 OWNERSHIP\\_STRENGTH QosPolicy on page 836](#) setting of SHARED). The maximum number of out-of-order DDS samples from any one *DataWriter* that can occupy in the receive queue is set in the `max_samples_per_remote_writer` field of the [48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 876](#); this value can be used to prevent a single *DataWriter* from using all the space in the receive queue. **`max_samples_per_remote_writer`** must be set to be  $\leq$  **`max_samples`**.

The *DataReader* will cache DDS samples that arrive out of order while waiting for missing DDS samples to be resent. (Up to 256 DDS samples can be resent; this limitation is imposed by the wire protocol.) If there is no room, the *DataReader* has to reject out-of-order DDS samples and request them again later after the missing DDS samples have arrived.

The appropriate size of the receive queue depends on application parameters, such as the *DataWriter's* sending rate and the probability of a dropped DDS sample. However, the receive queue size should generally be larger than the send queue size. Send queue size is discussed in [32.4.2.1 Understanding the Send Queue and Setting its Size on page 455](#).

[Figure 32.5: Effect of Receive-Queue Size on Performance: Large Queue Size on the next page](#) and [Figure 32.6: Effect of Receive Queue Size on Performance: Small Queue Size on page 461](#) compare two hypothetical *DataReaders*, both interacting with the same *DataWriter*. The queue on the left represents an ordering cache, allocated from receive queue—DDS samples are held here if they arrive out of order. The *DataReader* in [Figure 32.5: Effect of Receive-Queue Size on Performance: Large Queue Size on the next page](#) has a sufficiently large receive queue (**`max_samples`**) for the given send rate of the *DataWriter* and other operational parameters. In both cases, we assume that all DDS samples are

taken from the *DataReader* in the *Listener* callback. (See [41.3 Accessing DDS Data Samples with Read or Take](#) on page 665 for information on `take()` and related operations.)

In [Figure 32.6: Effect of Receive Queue Size on Performance: Small Queue Size](#) on the next page, `max_samples` is too small to cache out-of-order DDS samples for the same operational parameters. In both cases, the *DataReaders* eventually receive all the DDS samples in order. However, the *DataReader* with the larger `max_samples` will get the DDS samples earlier and with fewer transactions. In particular, DDS sample “4” is never resent for the *DataReader* with the larger queue size.

Figure 32.5: Effect of Receive-Queue Size on Performance: Large Queue Size

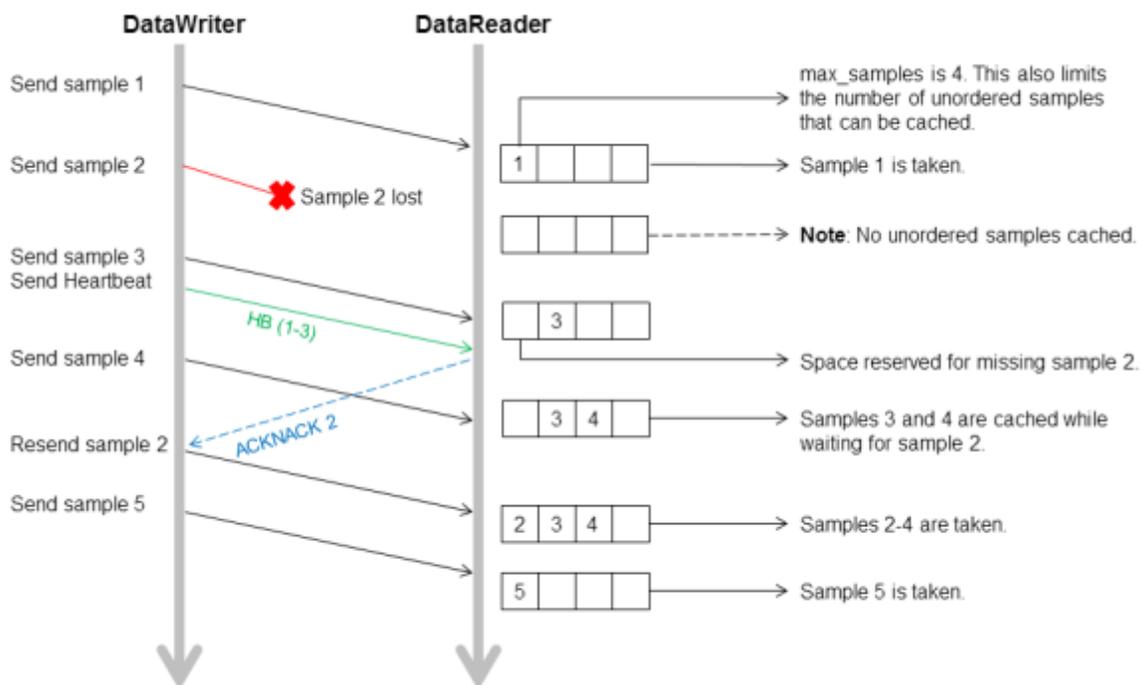

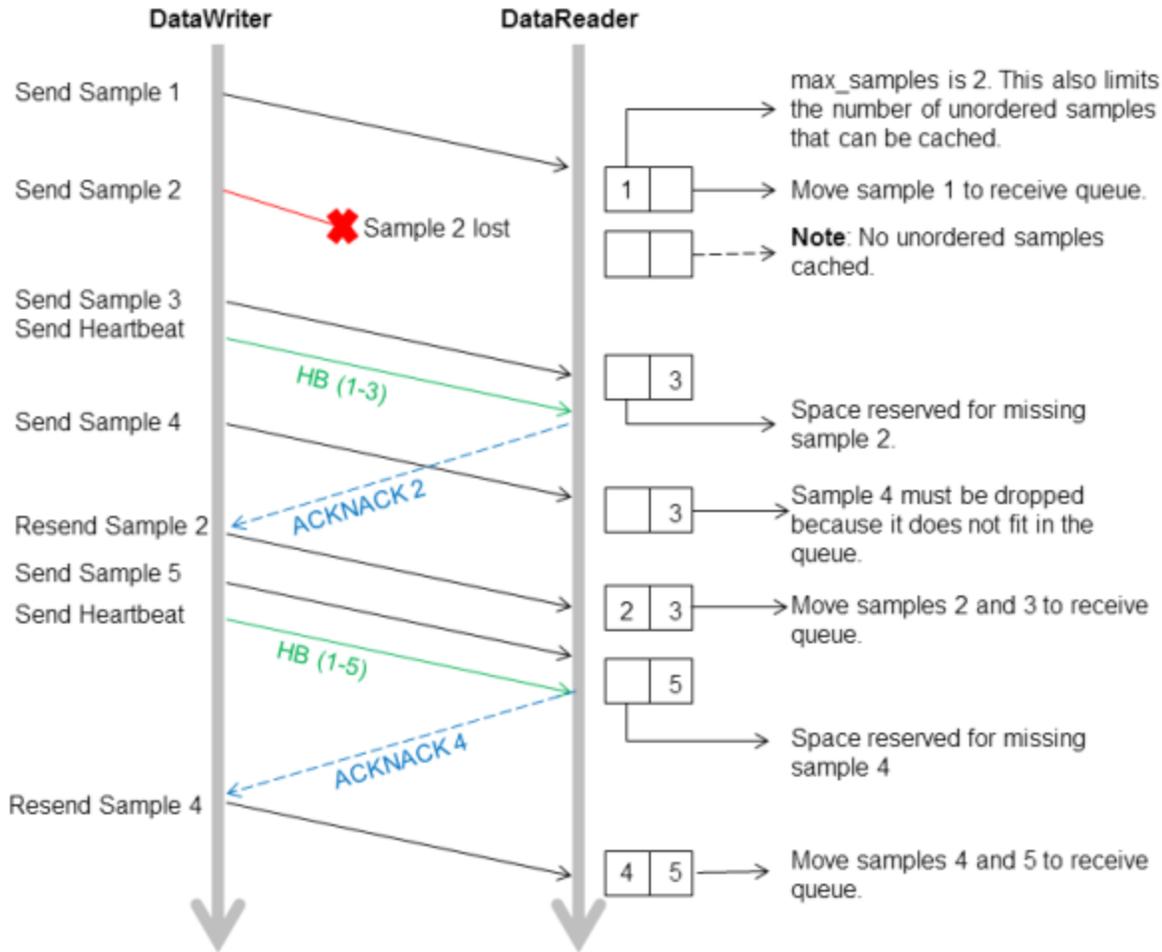

Figure 32.6: Effect of Receive Queue Size on Performance: Small Queue Size

### 32.4.3 Controlling Queue Depth with the History QosPolicy

If you want to achieve strict reliability, set the *kind* field in the [47.12 HISTORY QosPolicy on page 818](#) for both the *DataReader* and *DataWriter* to `KEEP_ALL`; in this case, the *depth* does not matter.

Or, for non-strict reliability, you can leave the **kind** set to `KEEP_LAST` (the default). This will provide non-strict reliability; some DDS samples may not be delivered if the resource limit is reached.

The **depth** field in the [47.12 HISTORY QosPolicy on page 818](#) controls how many DDS samples *Connext* will attempt to keep on the *DataWriter*'s send queue or the *DataReader*'s receive queue. For reliable communications, depth should be  $\geq 1$ . The depth can be set to 1, but cannot be more than the `max_samples_per_instance` in [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#).

Example:

- *DataWriter*

```
writer_qos.history.depth = <number of DDS samples to keep in send queue>;
```

- *DataReader*

```
reader_qos.history.depth = <number of DDS samples to keep in receive queue>;
```

## 32.4.4 Controlling Heartbeats and Retries with DataWriterProtocol QosPolicy

In the *Connex* reliability model, the *DataWriter* sends DDS data samples and heartbeats to reliable *DataReaders*. A *DataReader* responds to a heartbeat by sending an ACKNACK, which tells the *DataWriter* what the *DataReader* has received so far.

In addition, the *DataReader* can request missing DDS samples (by sending an ACKNACK) and the *DataWriter* will respond by resending the missing DDS samples. This section describes some advanced timing parameters that control the behavior of this mechanism. Many applications do not need to change these settings. These parameters are contained in the [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 788](#).

The protocol described in [32.3 Overview of the Reliable Protocol on page 448](#) uses very simple rules such as piggybacking HB messages to each DATA message and responding immediately to ACKNACKs with the requested repair messages. While correct, this protocol would not be capable of accommodating optimum performance in more advanced use cases.

This section describes some of the parameters configurable by means of the `rtps_reliable_writer` structure in the [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 788](#) and how they affect the behavior of the RTPS protocol.

### 32.4.4.1 How Often Heartbeats are Resent (heartbeat\_period)

If a *DataReader* does not acknowledge a DDS sample that has been sent, the *DataWriter* resends the heartbeat. These heartbeats are resent at the rate set in the [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 788](#), specifically its `heartbeat_period` field.

For example, a **heartbeat\_period** of 3 seconds means that if a *DataReader* does not receive the latest DDS sample (for example, it gets dropped by the network), it might take up to 3 seconds before the *DataReader* realizes it is missing data. The application can lower this value when it is important that recovery from packet loss is very fast.

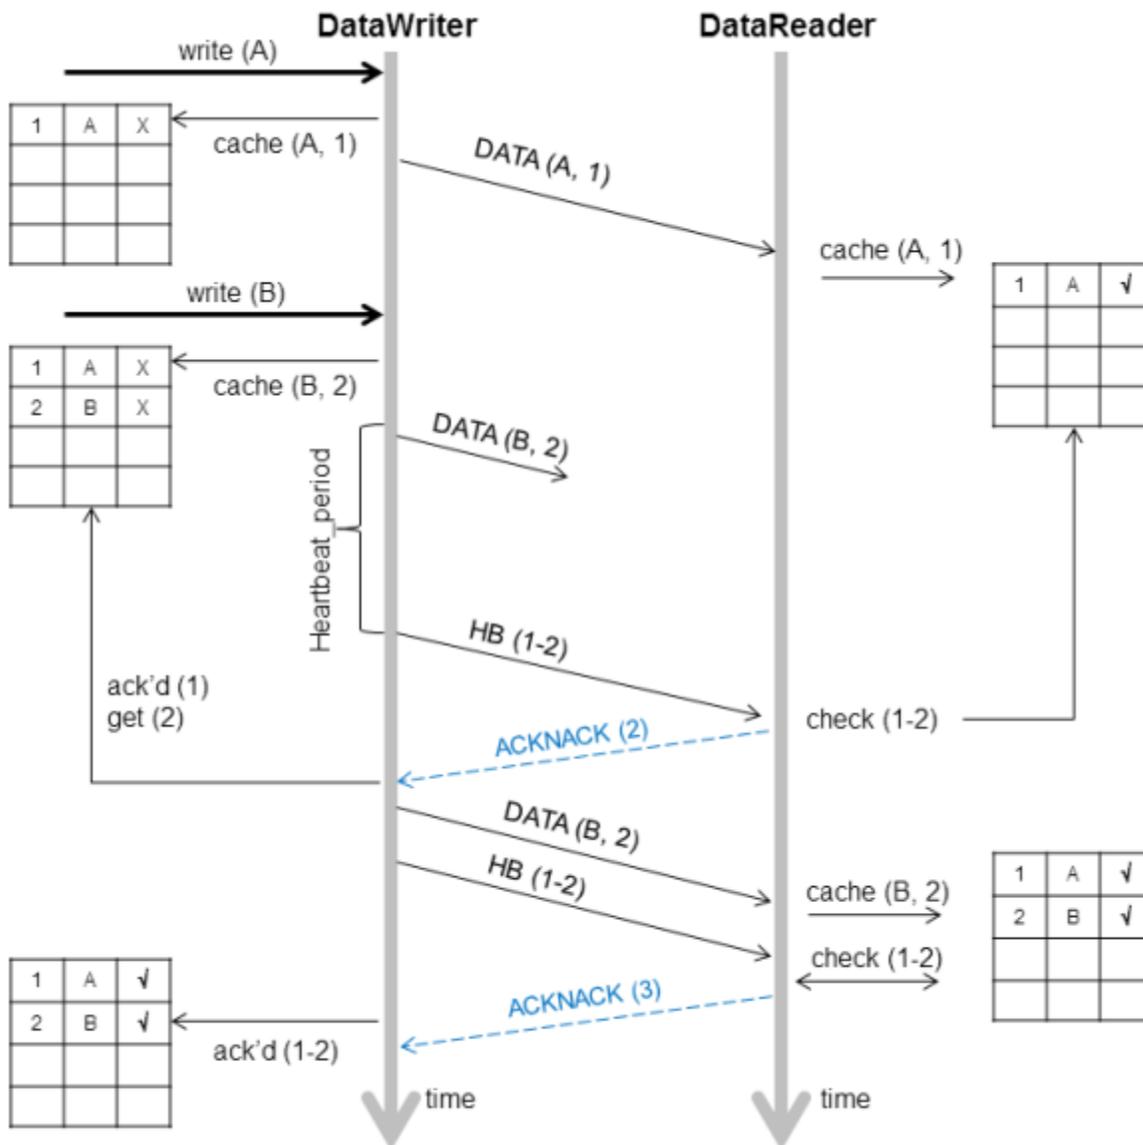

The basic approach of sending HB messages as a piggyback to DATA messages has the advantage of minimizing network traffic. However, there is a situation where this approach, by itself, may result in large latencies. Suppose there is a *DataWriter* that writes bursts of data, separated by relatively long periods of silence. Furthermore assume that the last message in one of the bursts is lost by the network.

This is the case shown for message DATA(B, 2) in [Figure 32.7: Use of heartbeat\\_period on the next page](#). If HBs were only sent piggybacked to DATA messages, the *DataReader* would not realize it missed the ‘B’ DATA message with sequence number ‘2’ until the *DataWriter* wrote the next message. This may be a long time if data is written sporadically. To avoid this situation, *Connex* can be configured so that HBs are sent periodically as long as there are DDS samples that have not been acknowledged even if no data is being sent. The period at which these HBs are sent is configurable by setting the `rtps_reliable_writer.heartbeat_period` field in the [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\)](#) on page 788.

Note that a small value for the `heartbeat_period` will result in a small worst-case latency if the last message in a burst is lost. This comes at the expense of the higher overhead introduced by more frequent HB messages.

Also note that the `heartbeat_period` should not be less than the `rtps_reliable_reader.heartbeat_suppression_duration` in the [48.1 DATA\\_READER\\_PROTOCOL QosPolicy \(DDS Extension\)](#) on page 871; otherwise those HBs will be lost.

Figure 32.7: Use of heartbeat\_period

#### 32.4.4.2 How Often Piggyback Heartbeats are Sent (`heartbeats_per_max_samples`)

A *DataWriter* will automatically send heartbeats with new DDS samples to request regular ACKNACKs from the *DataReader*. These are called “piggyback” heartbeats.

A piggyback heartbeat is sent every  $[(\text{current send-window size} / \text{heartbeats\_per\_max\_samples})]$  number of DDS samples written.

The `heartbeats_per_max_samples` field is part of the `rtps_reliable_writer` structure in the [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\)](#) on page 788. If `heartbeats_per_max_`

**samples** is set equal to **max\_send\_window\_size**, this means that a heartbeat will be sent with each DDS sample. A value of 8 means that a heartbeat will be sent with every 'current send-window size/8' DDS samples. Say current send window is 1024, then a heartbeat will be sent once every 128 DDS samples. If you set this to zero, DDS samples are sent without any piggyback heartbeat. The **max\_send\_window\_size** field is part of the [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 788](#).

[Figure 32.1: Basic RTPS Reliable Protocol](#) and [Figure 32.2: RTPS Reliable Protocol in the Presence of Message Loss](#) seem to imply that a heartbeat (HB) is sent as a piggyback to each DATA message. However, in situations where data is sent continuously at high rates, piggybacking a HB to each message may result in too much overhead; not so much on the HB itself, but on the ACKNACKs that would be sent back as replies by the *DataReader*.

There are two reasons to send a HB:

- To request that a *DataReader* confirm the receipt of data via an ACKNACK, so that the *DataWriter* can remove it from its send queue and therefore prevent the *DataWriter*'s history from filling up (which could cause the **write()** operation to temporarily block<sup>1</sup>).
- To inform the *DataReader* of what data it should have received, so that the *DataReader* can send a request for missing data via an ACKNACK.

The *DataWriter*'s send queue can buffer many DDS data samples while it waits for ACKNACKs, and the *DataReader*'s receive queue can store out-of-order DDS samples while it waits for missing ones. So it is possible to send HB messages much less frequently than DATA messages. The ratio of piggyback HB messages to DATA messages is controlled by the **rtps\_reliable\_writer.heartbeats\_per\_max\_samples** field in the [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 788](#).

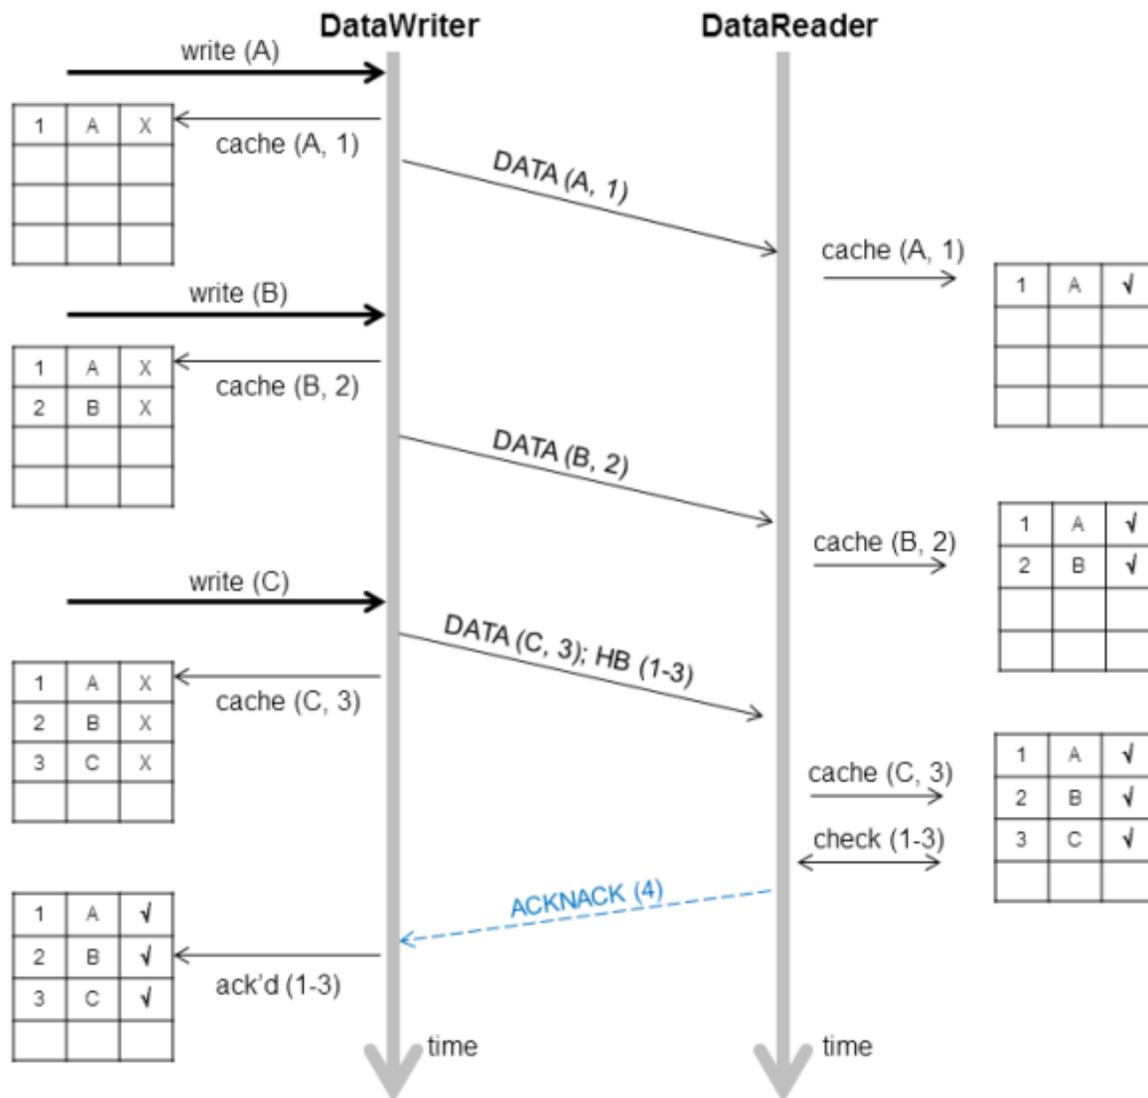

A HB is used to get confirmation from *DataReaders* so that the *DataWriter* can remove acknowledged DDS samples from the queue to make space for new DDS samples. Therefore, if the queue size is large, or new DDS samples are added slowly, HBs can be sent less frequently.

In [Figure 32.8: Use of heartbeats\\_per\\_max\\_samples on the next page](#), the *DataWriter* sets the **heartbeats\_per\_max\_samples** to certain value so that a piggyback HB will be sent for every three DDS samples. The *DataWriter* first writes DDS sample A and B. The *DataReader* receives both. However, since no HB has been received, the *DataReader* won't send back an ACKNACK. The *DataWriter* will still keep all the DDS samples in its queue. When the *DataWriter* sends DDS sample C, it will send a piggyback HB along with the DDS sample. Once the *DataReader* receives the HB, it will send back an ACKNACK for DDS samples up to sequence number 3, such that the *DataWriter* can remove all three DDS samples from its queue.

---

<sup>1</sup>Note that data could also be removed from the *DataWriter*'s send queue if it is no longer relevant due to some other QoS such a HISTORY KEEP\_LAST ([47.12 HISTORY QosPolicy on page 818](#)) or LIFESPAN ([47.14 LIFESPAN QoS Policy on page 824](#)).

Figure 32.8: Use of heartbeats\_per\_max\_samples

### 32.4.4.3 Controlling Packet Size for Resent DDS Samples (max\_bytes\_per\_nack\_response)

A DataWriter may resend multiple missed DDS samples in the same packet. The **max\_bytes\_per\_nack\_response** field in the [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\)](#) on [page 788](#) limits the size of this ‘repair’ packet. The reliable *DataWriter* will include at least one sample in the repair packet.

For example, if the *DataReader* requests 20 DDS samples, each 10K, and the **max\_bytes\_per\_nack\_response** is set to 100K, the *DataWriter* will only send the first 10 DDS samples at most. The *DataReader* will have to ACKNACK again to receive the other DDS samples.

Regardless of this setting, the maximum number of samples that can be part of a repair packet is limited to 32. This limit cannot be changed by configuration. In addition, the number of samples is limited by the value of `NDDS_Transport_Property_t`'s `gather_send_buffer_count_max` (see [51.6.1 Setting the Maximum Gather-Send Buffer Count for UDP Transports on page 977](#)).

#### 32.4.4.4 Controlling How Many Times Heartbeats are Resent (`max_heartbeat_retries`)

If a *DataReader* does not respond within `max_heartbeat_retries` number of heartbeats, it will be dropped by the *DataWriter* and the reliable *DataWriter*'s *Listener* will be called with a [31.6.9 RELIABLE\\_READER\\_ACTIVITY\\_CHANGED Status \(DDS Extension\) on page 408](#).

If the dropped *DataReader* becomes available again (perhaps its network connection was down temporarily), it will be added back to the *DataWriter* the next time the *DataWriter* receives some message (ACKNACK) from the *DataReader*.

When a *DataReader* is 'dropped' by a *DataWriter*, the *DataWriter* will not wait for the *DataReader* to send an ACKNACK before any DDS samples are removed. However, the *DataWriter* will still send data and HBs to this *DataReader* as normal.

The `max_heartbeat_retries` field is part of the [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 788](#).

#### 32.4.4.5 Treating Non-Progressing Readers as Inactive Readers (`inactivate_nonprogressing_readers`)

In addition to `max_heartbeat_retries`, if `inactivate_nonprogressing_readers` is set, then not only are non-responsive *DataReaders* considered inactive, but *DataReaders* sending non-progressing NACKs can also be considered inactive. A *non-progressing NACK* is one which requests the same oldest DDS sample as the previously received NACK. In this case, the *DataWriter* will not consider a non-progressing NACK as coming from an active reader, and hence will inactivate the *DataReader* if no new NACKs are received before `max_heartbeat_retries` number of heartbeat periods has passed.

One example for which it could be useful to turn on `inactivate_nonprogressing_readers` is when a *DataReader*'s (keep-all) queue is full of untaken historical DDS samples. Each subsequent heartbeat would trigger the same NACK, and nominally the *DataReader* would not be inactivated. A user not requiring strict-reliability could consider setting `inactivate_nonprogressing_readers` to allow the *DataWriter* to progress rather than being held up by this non-progressing *DataReader*.

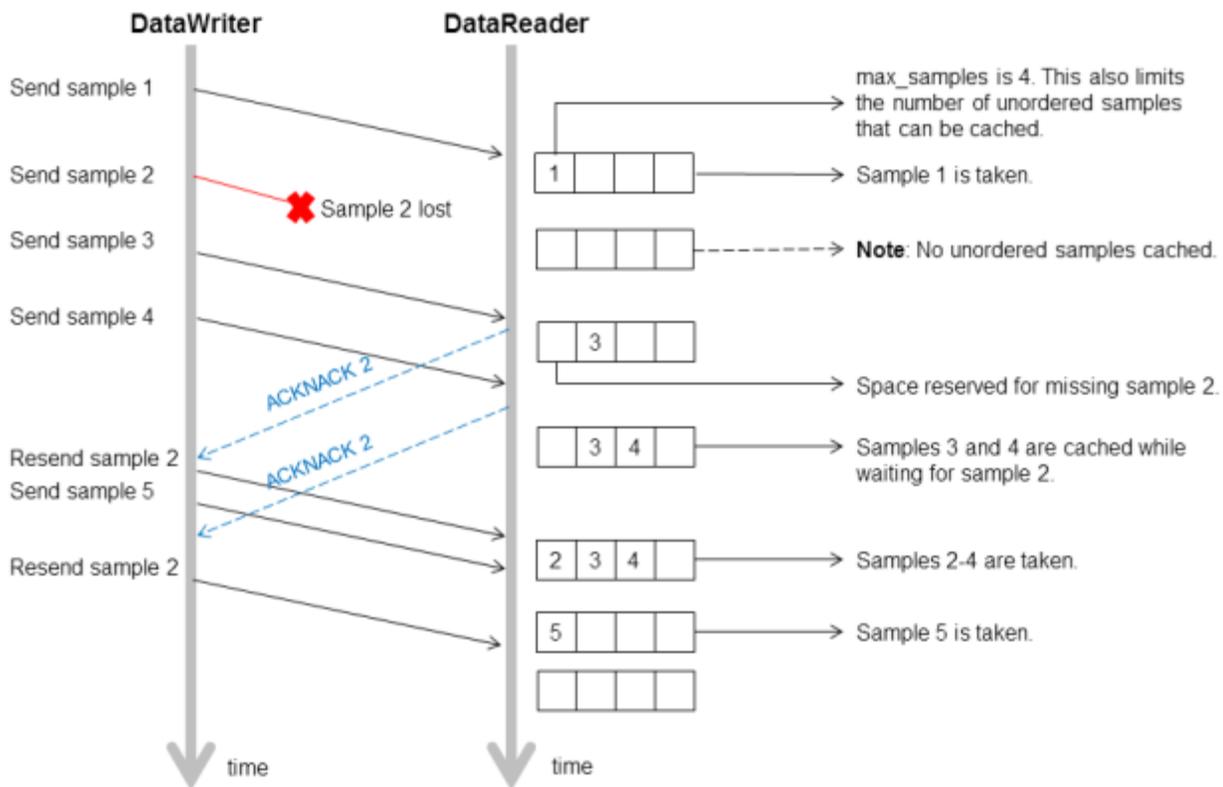

#### 32.4.4.6 Coping with Redundant Requests for Missing DDS Samples (`max_nack_response_delay`)

When a *DataWriter* receives a request for missing DDS samples from a *DataReader* and responds by resending the requested DDS samples, it will ignore additional requests for the same DDS samples during the time period `max_nack_response_delay`.

The `rtps_reliable_writer.max_nack_response_delay` field is part of the [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\)](#) on page 788.

If your send period is smaller than the round-trip delay of a message, this can cause unnecessary DDS sample retransmissions due to redundant ACKNACKs. In this situation, an ACKNACK triggered by an out-of-order DDS sample is not received before the next DDS sample is sent. When a *DataReader* receives the next message, it will send another ACKNACK for the missing DDS sample. As illustrated in [Figure 32.9: Resending Missing Samples due to Duplicate ACKNACKs](#) below, duplicate ACKNACK messages cause another resending of missing DDS sample “2” and lead to wasted CPU usage on both the publication and the subscription sides.

**Figure 32.9: Resending Missing Samples due to Duplicate ACKNACKs**

While these redundant messages provide an extra cushion for the level of reliability desired, you can conserve the CPU and network bandwidth usage by limiting how often the same ACKNACK messages are sent; this is controlled by `min_nack_response_delay`.

Reliable subscriptions are prevented from resending an ACKNACK within `min_nack_response_delay` seconds from the last time an ACKNACK was sent for the same DDS sample. Our testing shows that

the default **min\_nack\_response\_delay** of 0 seconds achieves an optimal balance for most applications on typical Ethernet LANs.

However, if your system has very slow computers and/or a slow network, you may want to consider increasing **min\_nack\_response\_delay**. Sending an ACKNACK and resending a missing DDS sample inherently takes a long time in this system. So you should allow a longer time for recovery of the lost DDS sample before sending another ACKNACK. In this situation, you should increase **min\_nack\_response\_delay**.

If your system consists of a fast network or computers, *and* the receive queue size is very small, then you should keep **min\_nack\_response\_delay** very small (such as the default value of 0). If the queue size is small, recovering a missing DDS sample is more important than conserving CPU and network bandwidth (new DDS samples that are too far ahead of the missing DDS sample are thrown away). A fast system can cope with a smaller **min\_nack\_response\_delay** value, and the reliable DDS sample stream can normalize more quickly.

#### 32.4.4.7 Disabling Positive Acknowledgements (**disable\_positive\_acks\_min\_sample\_keep\_duration**)

When ACKNACK storms are a primary concern in a system, an alternative to tuning heartbeat and ACKNACK response delays is to disable positive acknowledgments (ACKs) and rely just on NACKs to maintain reliability. Systems with non-strict reliability requirements can disable ACKs to reduce network traffic and directly solve the problem of ACK storms. ACKs can be disabled for the *DataWriter* and the *DataReader*; when disabled for the *DataWriter*, none of its *DataReaders* will send ACKs, whereas disabling it at the *DataReader* allows per-*DataReader* configuration.

Normally when ACKs are enabled, strict reliability is maintained by the *DataWriter*, guaranteeing that a DDS sample stays in its send queue until all *DataReaders* have positively acknowledged it (aside from relevant DURABILITY, HISTORY, and LIFESPAN QoS policies). When ACKs are disabled, strict reliability is no longer guaranteed, but the *DataWriter* should still keep the DDS sample for a sufficient duration for ACK-disabled *DataReaders* to have a chance to NACK it. Thus, a configurable “keep-duration” (**disable\_postive\_acks\_min\_sample\_keep\_duration**) applies for DDS samples written for ACK-disabled *DataReaders*, where DDS samples are kept in the queue for at least that keep-duration. After the keep-duration has elapsed for a DDS sample, the DDS sample is considered to be “acknowledged” by its ACK-disabled *DataReaders*.

The keep duration should be configured for the expected worst-case from when the DDS sample is written to when a NACK for the DDS sample could be received. If set too short, the DDS sample may no longer be queued when a NACK requests it, which is the cost of not enforcing strict reliability.

If the peak send rate is known and writer resources are available, the writer queue can be sized so that writes will not block. For this case, the queue size must be greater than the send rate multiplied by the keep duration.

## 32.4.5 Avoiding Message Storms with DataReaderProtocol QoSPolicy

*DataWriters* send DDS data samples and heartbeats to *DataReaders*. A *DataReader* responds to a heartbeat by sending an acknowledgement that tells the *DataWriter* what the *DataReader* has received so far and what it is missing. If there are many *DataReaders*, all sending ACKNACKs to the same *DataWriter* at the same time, a message storm can result. To prevent this, you can set a delay for each *DataReader*, so they don't all send ACKNACKs at the same time. This delay is set in the [48.1 DATA\\_READER\\_PROTOCOL QoSPolicy \(DDS Extension\)](#) on page 871.

If you have several *DataReaders* per *DataWriter*, varying this delay for each one can avoid ACKNACK message storms to the *DataWriter*. If you are not concerned about message storms, you do not need to change this QoSPolicy.

Example:

```
reader_qos.protocol.rtps_reliable_reader.min_heartbeat_response_delay.sec = 0;
reader_qos.protocol.rtps_reliable_reader.min_heartbeat_response_delay.nanosec = 0;
reader_qos.protocol.rtps_reliable_reader.max_heartbeat_response_delay.sec = 0;
reader_qos.protocol.rtps_reliable_reader.max_heartbeat_response_delay.nanosec =
    0.5 * 1000000000ULL; // 0.5 sec
```

As the name suggests, the minimum and maximum response delay bounds the random wait time before the response. Setting both to zero will force immediate response, which may be necessary for the fastest recovery in case of lost DDS samples.

## 32.4.6 Resending DDS Samples to Late-Joiners with the Durability QoSPolicy

The [47.9 DURABILITY QoSPolicy on page 809](#) is also somewhat related to Reliability. *Connex* requires a finite time to "discover" or match *DataReaders* to *DataWriters*. If an application attempts to send data before the *DataReader* and *DataWriter* "discover" one another, then the DDS sample will not actually get sent. Whether or not DDS samples are resent when the *DataReader* and *DataWriter* eventually "discover" one another depends on how the DURABILITY and [47.12 HISTORY QoSPolicy on page 818](#) are set. The default setting for the Durability QoSPolicy is VOLATILE, which means that the *DataWriter* will not store DDS samples for redelivery to late-joining *DataReaders*.

*Connex* also supports the TRANSIENT\_LOCAL setting for the Durability, which means that the DDS samples will be kept stored for redelivery to late-joining *DataReaders*, as long as the *DataWriter* is around. The DDS samples are not stored beyond the lifecycle of the *DataWriter*.

How many samples are sent to late-joining *DataReaders* is determined by the **writer\_depth** in the DURABILITY QoSPolicy.

See also: [40.6 Waiting for Historical Data on page 625](#).

## 32.4.7 Use Cases

This section contains advanced material that discusses practical applications of the reliability related QoS.

### 32.4.7.1 Importance of Relative Thread Priorities

For high throughput, the *Connex* Event thread’s priority must be sufficiently high on the sending application. Unlike an unreliable writer, a reliable writer relies on internal *Connex* threads: the Receive thread processes ACKNACKs from the *DataReaders*, and the Event thread schedules the events necessary to maintain reliable data flow.

- When DDS samples are sent to the same or another application on the same host, the Receive thread priority should be higher than the writing thread priority (priority of the thread calling **write()** on the *DataWriter*). This will allow the Receive thread to process the messages as they are sent by the writing thread. A sustained reliable flow requires the reader to be able to process the DDS samples from the writer at a speed equal to or faster than the writer emits.
- The default Event thread priority is low. This is adequate if your reliable transfer is not sustained; queued up events will eventually be processed when the writing thread yields the CPU. The *Connex* can automatically grow the event queue to store all pending events. But if the reliable communication is sustained, reliable events will continue to be scheduled, and the event queue will eventually reach its limit. The default Event thread priority is unsuitable for maintaining a fast and sustained reliable communication and should be increased through the **participant\_qos.event.thread.priority**. This value maps directly to the OS thread priority, see [44.5 EVENT QoS Policy \(DDS Extension\) on page 721](#)).

The Event thread should also be increased to minimize the reliable latency. If events are processed at a higher priority, dropped packets will be resent sooner.

Now we consider some practical applications of the reliability related QoS:

- [32.4.7.2 Aperiodic Use Case: One-at-a-Time below](#)
- [32.4.7.3 Aperiodic, Bursty on page 476](#)
- [32.4.7.4 Periodic on page 479](#)

### 32.4.7.2 Aperiodic Use Case: One-at-a-Time

Suppose you have aperiodically generated data that needs to be delivered reliably, with minimum latency, such as a series of commands (“Ready,” “Aim,” “Fire”). If a writing thread may block between each DDS sample to guarantee reception of the just-sent DDS sample on the reader’s middleware end, a smaller queue will provide a smaller upper bound on the DDS sample delivery time. Adequate writer QoS for this use case are presented in [Figure 32.10: QoS for an Aperiodic, One-at-a-time Reliable Writer below](#).

**Figure 32.10: QoS for an Aperiodic, One-at-a-time Reliable Writer**

```
1. qos->reliability.kind = DDS_RELIABLE_RELIABILITY_QOS;
2. qos->history.kind = DDS_KEEP_ALL_HISTORY_QOS;
3. qos->protocol.push_on_write = DDS_BOOLEAN_TRUE;
```

```

4.
5. //use these hard coded value unless you use a key
6. qos->resource_limits.initial_samples = qos->resource_limits.max_samples = 1;
7. qos->resource_limits.max_samples_per_instance =
8. qos->resource_limits.max_samples;
9. qos->resource_limits.initial_instances =
10. qos->resource_limits.max_instances = 1;
11.
12. // want to piggyback HB w/ every sample.
13. qos->protocol.rtps_reliable_writer.heartbeats_per_max_samples =
14. qos->resource_limits.max_samples;
15.
16. qos->protocol.rtps_reliable_writer.high_watermark = 1;
17. qos->protocol.rtps_reliable_writer.low_watermark = 0;
18. qos->protocol.rtps_reliable_writer.min_nack_response_delay.sec = 0;
19. qos->protocol.rtps_reliable_writer.min_nack_response_delay.nanosec = 0;
20. //consider making non-zero for reliable multicast
21. qos->protocol.rtps_reliable_writer.max_nack_response_delay.sec = 0;
22. qos->protocol.rtps_reliable_writer.max_nack_response_delay.nanosec = 0;
23.
24. // should be faster than the send rate, but be mindful of OS resolution
25. 25 qos->protocol.rtps_reliable_writer.fast_heartbeat_period.sec = 0;
26. 26 qos->protocol.rtps_reliable_writer.fast_heartbeat_period.nanosec =
27. alertReaderWithinThisMs * 1000000;
28.
29. qos->reliability.max_blocking_time = blockingTime;
30. qos->protocol.rtps_reliable_writer.max_heartbeat_retries = 7;
31.
32. // essentially turn off slow HB period
33. qos->protocol.rtps_reliable_writer.heartbeat_period.sec = 3600 * 24 * 7;

```

[Line 1 \(Figure 32.10: QoS for an Aperiodic, One-at-a-time Reliable Writer on the previous page\)](#): This is the default setting for a writer, shown here strictly for clarity.

[Line 2 \(Figure 32.10: QoS for an Aperiodic, One-at-a-time Reliable Writer on the previous page\)](#): Setting the History kind to KEEP\_ALL guarantees that no DDS sample is ever lost.

[Line 3 \(Figure 32.10: QoS for an Aperiodic, One-at-a-time Reliable Writer on the previous page\)](#): This is the default setting for a writer, shown here strictly for clarity. ‘Push’ mode reliability will yield lower latency than ‘pull’ mode reliability in normal situations where there is no DDS sample loss. (See [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 788](#).) Furthermore, it does not matter that each packet sent in response to a command will be small, because our data sent with each command is likely to be small, so that maximizing throughput for this data is not a concern.

[Line 5 - Line 10 \(Figure 32.10: QoS for an Aperiodic, One-at-a-time Reliable Writer on the previous page\)](#): For this example, we assume a single writer is writing DDS samples one at a time. If we are not using keys (see [Chapter 8 DDS Samples, Instances, and Keys on page 17](#)), there is no reason to use a queue with room for more than one DDS sample, because we want to resolve a DDS sample completely before moving on to the next. While this negatively impacts throughput, it minimizes memory usage. In this example, a written DDS sample will remain in the queue until it is acknowledged by all active readers (only 1 for this example).

[Line 12 - Line 14 \(Figure 32.10: QoS for an Aperiodic, One-at-a-time Reliable Writer on the previous page\)](#): The fastest way for a writer to ensure that a reader is up-to-date is to force an acknowledgment

with every DDS sample. We do this by appending a Heartbeat with every DDS sample. This is akin to a certified mail; the writer learns—as soon as the system will allow—whether a reader has received the letter, and can take corrective action if the reader has not. As with certified mail, this model has significant overhead compared to the unreliable case, trading off lower packet efficiency in favor of latency and fast recovery.

[Line 16-Line 17 \(Figure 32.10: QoS for an Aperiodic, One-at-a-time Reliable Writer on page 471\)](#): Since the writer takes responsibility for pushing the DDS samples out to the reader, a writer will go into a “heightened alert” mode as soon as the high water mark is reached (which is when any DDS sample is written for this writer) and only come out of this mode when the low water mark is reached (when all DDS samples have been acknowledged for this writer). Note that the selected high and low watermarks are actually the default values.

[Line 18-Line 22 \(Figure 32.10: QoS for an Aperiodic, One-at-a-time Reliable Writer on page 471\)](#): When a reader requests a lost DDS sample, we respond to the reader immediately in the interest of faster recovery. If the readers receive packets on unicast, there is no reason to wait, since the writer will eventually have to feed individual readers separately anyway. In case of multicast readers, it makes sense to consider further. If the writer delayed its response enough so that all or most of the readers have had a chance to NACK a DDS sample, the writer may coalesce the requests and send just one packet to all the multicast readers. Suppose that all multicast readers do indeed NACK within approximately 100  $\mu$ sec. Setting the minimum and maximum delays at 100  $\mu$ sec will allow the writer to collect all these NACKs and send a single response over multicast. (See [47.5 DATA\\_WRITER\\_PROTOCOL QoSPolicy \(DDS Extension\) on page 788](#) for information on setting `min_nack_response_delay` and `max_nack_response_delay`.) Note that *Connex* relies on the OS to wait for this 100  $\mu$ sec. Unfortunately, not all operating systems can sleep for such a fine duration. On Windows systems, for example, the minimum achievable sleep time is somewhere between 1 to 20 milliseconds, depending on the version. On VxWorks systems, the minimum resolution of the wait time is based on the tick resolution, which is 1/system clock rate (thus, if the system clock rate is 100 Hz, the tick resolution is 10 millisecond). On such systems, the achievable minimum wait is actually far larger than the desired wait time. This could have an unintended consequence due to the delay caused by the OS; at a minimum, the time to repair a packet may be longer than you specified.

[Line 24-Line 27 \(Figure 32.10: QoS for an Aperiodic, One-at-a-time Reliable Writer on page 471\)](#): If a reader drops a DDS sample, the writer recovers by notifying the reader of what it has sent, so that the reader may request resending of the rejected DDS sample. Therefore, the recovery time depends primarily on how quickly the writer pings the reader that has fallen behind. If commands will not be generated faster than one every few seconds, it may be acceptable for the writer to ping the reader several hundred milliseconds after the DDS sample is sent.

- Suppose that the round-trip time of fairly small packets between the writer and the reader application is 50 microseconds, and that the reader does not delay response to a Heartbeat from the writer (see [48.1 DATA\\_READER\\_PROTOCOL QoSPolicy \(DDS Extension\) on page 871](#) for how to change this). If a DDS sample is dropped by the network, the writer will ping the reader

after a maximum of the OS delay resolution discussed above and **alertReaderWithinThisMs** (let's say 10 ms for this example). The reader will request the missing DDS sample immediately, and with the code set as above, the writer will feed the missing DDS sample immediately. Neglecting the processing time on the writer or the reader end, and assuming that this retry succeeds, the time to recover the DDS sample from the original publication time is: **alertReaderWithinThisMs + 50  $\mu$ sec + 25  $\mu$ sec**.

If the OS is capable of micro-sleep, the recovery time can be within 100  $\mu$ sec, barely noticeable to a human operator. If the OS minimum wait resolution is much larger, the recovery time is dominated by the wait resolution of the OS. Since ergonomic studies suggest that delays in excess of a 0.25 seconds start hampering operations that require low latency data, even a 10 ms limitation seems to be acceptable.

- What if two packets are dropped in a row? Then the recovery time would be **2 \* alertReaderWithinThisMs + 2 \* 50  $\mu$ sec + 25  $\mu$ sec**. If **alertReaderWithinThisMs** is 100 ms, the recovery time now exceeds 200 ms, and can perhaps degrade user experience.

[Line 29-Line 30 \(Figure 32.10: QoS for an Aperiodic, One-at-a-time Reliable Writer on page 471\)](#):

What if another command (like another button press) is issued before the recovery? Since we must not drop this new DDS sample, we block the writer until the recovery completes. If **alertReaderWithinThisMs** is 10 ms, and we assume no more than 7 consecutive drops, the longest time for recovery will be just above (**alertReaderWithinThisMs \* max\_heartbeat\_retries**), or 70 ms.

So if we set **blockingTime** to about 80 ms, we will have given enough chance for recovery. Of course, in a dynamic system, a reader may drop out at any time, in which case **max\_heartbeat\_retries** will be exceeded, and the unresponsive reader will be dropped by the writer. In either case, the writer can continue writing. Inappropriate values will cause a writer to prematurely drop a temporarily unresponsive (but otherwise healthy) reader, or be stuck trying unsuccessfully to feed a crashed reader. In the unfortunate case where a reader becomes temporarily unresponsive for a duration exceeding (**alertReaderWithinThisMs \* max\_heartbeat\_retries**), the writer may issue gaps to that reader when it becomes active again; the dropped DDS samples are irrecoverable. So estimating the worst case unresponsive time of all potential readers is critical if DDS sample drop is unacceptable.

[Line 33 \(Figure 32.10: QoS for an Aperiodic, One-at-a-time Reliable Writer on page 471\)](#): Since the command may not be issued for hours or even days on end, there is no reason to keep announcing the writer's state to the readers.

[Figure 32.11: QoS for an Aperiodic, One-at-a-time Reliable Reader below](#) shows how to set the QoS for the reader side, followed by a line-by-line explanation.

### Figure 32.11: QoS for an Aperiodic, One-at-a-time Reliable Reader

```
1. qos->reliability.kind = DDS_RELIABLE_RELIABILITY_QOS;
2. qos->history.kind = DDS_KEEP_ALL_HISTORY_QOS;
3.
```

```

4. // 1 is ok for normal use. 2 allows fast infinite loop
5. qos->reader_resource_limits.max_samples_per_remote_writer = 2;
6. qos->resource_limits.initial_samples = 2;
7. qos->resource_limits.initial_instances = 1;
8.
9. qos->protocol.rtps_reliable_reader.max_heartbeat_response_delay.sec = 0;
10. qos->protocol.rtps_reliable_reader.max_heartbeat_response_delay.nanosec = 0;
11. qos->protocol.rtps_reliable_reader.min_heartbeat_response_delay.sec = 0;
12. qos->protocol.rtps_reliable_reader.min_heartbeat_response_delay.nanosec = 0;

```

[Line 1-Line 2 \(Figure 32.11: QoS for an Aperiodic, One-at-a-time Reliable Reader on the previous page\)](#): Unlike a writer, the reader’s default reliability setting is best-effort, so reliability must be turned on. Since we don’t want to drop anything, we choose `KEEP_ALL` history.

[Line 4-Line 6 \(Figure 32.11: QoS for an Aperiodic, One-at-a-time Reliable Reader on the previous page\)](#): Since we enforce reliability on each DDS sample, it would be sufficient to keep the queue size at 1, except in the following case: suppose that the reader takes some action in response to the command received, which in turn causes the writer to issue another command right away. Because *Connex* passes the user data up to the application even before acknowledging the DDS sample to the writer (for minimum latency), the first DDS sample is still pending for acknowledgement in the writer’s queue when the writer attempts to write the second DDS sample, and will cause the writing thread to block until the reader completes processing the first DDS sample and acknowledges it to the writer; all are as they should be. But if you want to run this infinite loop at full throttle, the reader should buffer one more DDS sample. Let’s follow the packets flow under a normal circumstance:

1. The sender application writes DDS sample 1 to the reader. The receiver application processes it and sends a user-level response 1 to the sender application, but has not yet ACK’d DDS sample 1.
2. The sender application writes DDS sample 2 to the receiving application in response to response 1. Because the reader’s queue is 2, it can accept DDS sample 2 even though it may not yet have acknowledged DDS sample 1. Otherwise, the reader may drop DDS sample 2, and would have to recover it later.
3. At the same time, the receiver application acknowledges DDS sample 1, and frees up one slot in the queue, so that it can accept DDS sample 3, which it on its way.

The above steps can be repeated ad-infinitum in a continuous traffic.

[Line 7 \(Figure 32.11: QoS for an Aperiodic, One-at-a-time Reliable Reader on the previous page\)](#): Since we are not using keys, there is just one instance.

[Line 9-Line 12 \(32.4.7 Use Cases on page 470\)](#): We choose immediate response in the interest of fastest recovery. In high throughput, multicast scenario, delaying the response (with event thread priority set high of course) may decrease the likelihood of NACK storm causing a writer to drop some NACKs. This random delay reduces this chance by staggering the NACK response. But the minimum delay achievable once again depends on the OS.

### 32.4.7.3 Aperiodic, Bursty

Suppose you have aperiodically generated bursts of data, as in the case of a new aircraft approaching an airport. The data may be the same or different, but if they are written by a single writer, the challenge to this writer is to feed all readers as quickly and efficiently as possible when this burst of hundreds or thousands of DDS samples hits the system.

If you use an unreliable writer to push this burst of data, some of them may be dropped over an unreliable transport such as UDP.

If you try to shape the burst according to however much the slowest reader can process, the system throughput may suffer, and places an additional burden of queuing the DDS samples on the sender application.

If you push the data reliably as fast they are generated, this may cost dearly in repair packets, especially to the slowest reader, which is already burdened with application chores.

*Connex* pull mode reliability offers an alternative in this case by letting each reader pace its own data stream. It works by notifying the reader what it is missing, then waiting for it to request only as much as it can handle. As in the aperiodic one-at-a-time case ([32.4.7.2 Aperiodic Use Case: One-at-a-Time on page 471](#)), multicast is supported, but its performance depends on the resolution of the minimum delay supported by the OS. At the cost of greater latency, this model can deliver reliability while using far fewer packets than in the push mode. The writer QoS is given in [Figure 32.12: QoS for an Aperiodic, Bursty Writer below](#), with a line-by-line explanation below.

**Figure 32.12: QoS for an Aperiodic, Bursty Writer**

```

1. qos->reliability.kind = DDS_RELIABLE_RELIABILITY_QOS;
2. qos->history.kind = DDS_KEEP_ALL_HISTORY_QOS;
3. qos->protocol.push_on_write = DDS_BOOLEAN_FALSE;
4.
5. //use these hard coded value until you use key
6. qos->resource_limits.initial_instances =
7. qos->resource_limits.max_instances = 1;
8. qos->resource_limits.initial_samples = qos->resource_limits.max_samples
9.     = worstBurstInSample;
10. qos->resource_limits.max_samples_per_instance =
11. qos->resource_limits.max_samples;
12.
13. // piggyback HB not used
14. qos->protocol.rtps_reliable_writer.heartbeats_per_max_samples = 0;
15.
16. qos->protocol.rtps_reliable_writer.high_watermark = 1;
17. qos->protocol.rtps_reliable_writer.low_watermark = 0;
18.
19. qos->protocol.rtps_reliable_writer.min_nack_response_delay.sec = 0;
20. qos->protocol.rtps_reliable_writer.min_nack_response_delay.nanosec = 0;
21. qos->protocol.rtps_reliable_writer.max_nack_response_delay.sec = 0;
22. qos->protocol.rtps_reliable_writer.max_nack_response_delay.nanosec = 0;
23. qos->reliability.max_blocking_time = blockingTime;
24.
25. // should be faster than the send rate, but be mindful of OS resolution
26. qos->protocol.rtps_reliable_writer.fast_heartbeat_period.sec = 0;

```

```

27. qos->protocol.rtps_reliable_writer.fast_heartbeat_period.nanosec =
28.     alertReaderWithinThisMs * 1000000;
29. qos->protocol.rtps_reliable_writer.max_heartbeat_retries = 5;
30.
31. // essentially turn off slow HB period
32. qos->protocol.rtps_reliable_writer.heartbeat_period.sec = 3600 * 24 * 7;

```

[Line 1 \(Figure 32.12: QoS for an Aperiodic, Bursty Writer on the previous page\)](#): This is the default setting for a writer, shown here strictly for clarity.

[Line 2 \(Figure 32.12: QoS for an Aperiodic, Bursty Writer on the previous page\)](#): Since we do not want any data lost, we want the History kind set to `KEEP_ALL`.

[Line 3 \(Figure 32.12: QoS for an Aperiodic, Bursty Writer on the previous page\)](#): The default *Connex* reliable writer will push, but we want the reader to pull instead.

[Line 5-Line 11 \(Figure 32.12: QoS for an Aperiodic, Bursty Writer on the previous page\)](#): We assume a single instance, in which case the maximum DDS sample count will be the same as the maximum DDS sample count per writer. In contrast to the one-at-a-time case discussed in [32.4.7.2 Aperiodic Use Case: One-at-a-Time on page 471](#), the writer's queue is large; as big as the burst size in fact, but no more because this model tries to resolve a burst within a reasonable period, to be computed shortly. Of course, we could block the writing thread in the middle of the burst, but that might complicate the design of the sending application.

[Line 13-Line 14 \(Figure 32.12: QoS for an Aperiodic, Bursty Writer on the previous page\)](#): By a 'piggy-back' Heartbeat, we mean only a Heartbeat that is appended to data being pushed from the writer. Strictly speaking, the writer will also append a Heartbeat with each reply to a reader's lost DDS sample request, but we call that a 'framing' Heartbeat. Since data is pulled, `heartbeats_per_max_samples` is ignored.

[Line 16-Line 17 \(Figure 32.12: QoS for an Aperiodic, Bursty Writer on the previous page\)](#): Similar to the previous aperiodic writer, this writer spends most of its time idle. But as the name suggests, even a single new DDS sample implies more DDS sample to follow in a burst. Putting the writer into a fast mode quickly will allow readers to be notified soon. Only when all DDS samples have been delivered, the writer can rest.

[Line 19- Line 23 \(Figure 32.12: QoS for an Aperiodic, Bursty Writer on the previous page\)](#): Similar to the one-at-a-time case, there is no reason to delay response with only one reader. In this case, we can estimate the time to resolve a burst with only a few parameters. Let's say that the reader figures it can safely receive and process 20 DDS samples at a time without being overwhelmed, and that the time it takes a writer to fetch these 20 DDS samples and send a single packet containing these 20 DDS samples, plus the time it takes a reader to receive and process these DDS samples, and send another request back to the writer for the next 20 DDS samples is 11 ms. Even on the same hardware, if the reader's processing time can be reduced, this time will decrease; other factors such as the traversal time through *Connex* and the transport are typically in microseconds range (depending on machines of course).

For example, let's also say that the worst case burst is 1000 DDS samples. The writing thread will of course not block because it is merely copying each of the 1000 DDS samples to the *Connex* queue on the writer side; on a typical modern machine, the act of writing these 1000 DDS samples will probably take no more than a few ms. But it would take at least  $1000/20 = 50$  resend packets for the reader to catch up to the writer, or  $50 \times 11 \text{ ms} = 550 \text{ ms}$ . Since the burst model deals with one burst at a time, we would expect that another burst would not come within this time, and that we are allowed to block for at least this period. Including a safety margin, it would appear that we can comfortably handle a burst of 1000 every second or so.

But what if there are multiple readers? The writer would then take more time to feed multiple readers, but with a fast transport, a few more readers may only increase the 11 ms to only 12 ms or so. Eventually, however, the number of readers will justify the use of multicast. Even in pull mode, *Connex* supports multicast by measuring how many multicast readers have requested DDS sample repair. If the writer does not delay response to NACK, then repairs will be sent in unicast. But a suitable NACK delay allows the writer to collect potentially NACKs from multiple readers, and feed a single multicast packet. But as discussed in [32.4.7.2 Aperiodic Use Case: One-at-a-Time on page 471](#), by delaying reply to coalesce response, we may end up waiting much longer than desired. On a Windows system with 10 ms minimum sleep achievable, the delay would add at least 10 ms to the 11 ms delay, so that the time to push 1000 DDS samples now increases to  $50 \times 21 \text{ ms} = 1.05 \text{ seconds}$ . It would appear that we will not be able to keep up with incoming burst if it came at roughly 1 second, although we put fewer packets on the wire by taking advantage of multicast.

[Line 25-Line 28 \(32.4.7 Use Cases on page 470\)](#): We now understand how the writer feeds the reader in response to the NACKs. But how does the reader realize that it is behind? The writer notifies the reader with a Heartbeat to kick-start the exchange. Therefore, the latency will be lower bound by the writer's fast heartbeat period. If the application is not particularly sensitive to latency, the minimum wait time supported by the OS (10 ms on Windows systems, for example) might be a reasonable value.

[Line 29 \(Figure 32.12: QoS for an Aperiodic, Bursty Writer on page 476\)](#): With a fast heartbeat period of 50 ms, a writer will take 500 ms (50 ms times the default `max_heartbeat_retries` of 10) to write-off an unresponsive reader. If a reader crashes while we are writing a lot of DDS samples per second, the writer queue may completely fill up before the writer has a chance to drop the crashed reader. Lowering `max_heartbeat_retries` will prevent that scenario.

[Line 31-Line 32 \(Figure 32.12: QoS for an Aperiodic, Bursty Writer on page 476\)](#): For an aperiodic writer, turning off slow periodic Heartbeats will remove unwanted traffic from the network.

[Figure 32.13: QoS for an Aperiodic, Bursty Reader below](#) shows example code for a corresponding aperiodic, bursty reader.

**Figure 32.13: QoS for an Aperiodic, Bursty Reader**

```
1. qos->reliability.kind = DDS_RELIABLE_RELIABILITY_QOS;
2. qos->history.kind = DDS_KEEP_ALL_HISTORY_QOS;
3. qos->resource_limits.initial_samples =
4. qos->resource_limits.max_samples =
```

```

5. qos->reader_resource_limits.max_samples_per_remote_writer = 32;
6.
7. //use these hard coded value until you use key
8. qos->resource_limits.max_samples_per_instance =
9. qos->resource_limits.max_samples;
10. qos->resource_limits.initial_instances =
11. qos->resource_limits.max_instances = 1;
12.
13. // the writer probably has more for the reader; ask right away
14. qos->protocol.rtps_reliable_reader.min_heartbeat_response_delay.sec = 0;
15. qos->protocol.rtps_reliable_reader.min_heartbeat_response_delay.nanosec = 0;
16. qos->protocol.rtps_reliable_reader.max_heartbeat_response_delay.sec = 0;
17. qos->protocol.rtps_reliable_reader.max_heartbeat_response_delay.nanosec = 0;

```

[Line 1-Line 2 \(Figure 32.13: QoS for an Aperiodic, Bursty Reader on the previous page\)](#): Unlike a writer, the reader’s default reliability setting is best-effort, so reliability must be turned on. Since we don’t want to drop anything, we choose `KEEP_ALL` for the History QoS kind.

[Line 3-Line 5 \(Figure 32.13: QoS for an Aperiodic, Bursty Reader on the previous page\)](#): Unlike the writer, the reader’s queue can be kept small, since the reader is free to send ACKs for as much as it wants anyway. In general, the larger the queue, the larger the packet needs to be, and the higher the throughput will be. When the reader NACKs for lost DDS sample, it will only ask for this much.

[Line 7-Line 11 \(Figure 32.13: QoS for an Aperiodic, Bursty Reader on the previous page\)](#): We do not use keys in this example.

[Line 13-Line 17 \(Figure 32.13: QoS for an Aperiodic, Bursty Reader on the previous page\)](#): We respond immediately to catch up as soon as possible. When there are many readers, this may cause a NACK storm, as discussed in the reader code for one-at-a-time reliable reader.

#### 32.4.7.4 Periodic

In a periodic reliable model, we can use the writer and the reader queue to keep the data flowing at a smooth rate. The data flows from the sending application to the writer queue, then to the transport, then to the reader queue, and finally to the receiving application. Unless the sending application or any one of the receiving applications becomes unresponsive (including a crash) for a noticeable duration, this flow should continue uninterrupted.

The latency will be low in most cases, but will be several times higher for the recovered and many subsequent DDS samples. In the event of a disruption (e.g., loss in transport, or one of the readers becoming temporarily unresponsive), the writer’s queue level will rise, and may even block in the worst case. If the writing thread must not block, the writer’s queue must be sized sufficiently large to deal with any fluctuation in the system. [Figure 32.14: QoS for a Periodic Reliable Writer below](#) shows an example, with line-by-line analysis below.

**Figure 32.14: QoS for a Periodic Reliable Writer**

```

1. qos->reliability.kind = DDS_RELIABLE_RELIABILITY_QOS;
2. qos->history.kind = DDS_KEEP_ALL_HISTORY_QOS;
3. qos->protocol.push_on_write = DDS_BOOLEAN_TRUE;
4.

```

```

5. //use these hard coded value until you use key
6. qos->resource_limits.initial_instances =
7. qos->resource_limits.max_instances = 1;
8.
9. int unresolvedSamplePerRemoteWriterMax =
10.     worstCaseApplicationDelayTimeInMs * dataRateInHz / 1000;
11. qos->resource_limits.max_samples = unresolvedSamplePerRemoteWriterMax;
12. qos->resource_limits.initial_samples = qos->resource_limits.max_samples/2;
13. qos->resource_limits.max_samples_per_instance =
14.     qos->resource_limits.max_samples;
15.
16. int piggybackEvery = 8;
17. qos->protocol.rtps_reliable_writer.heartbeats_per_max_samples =
18.     qos->resource_limits.max_samples / piggybackEvery;
19.
20. qos->protocol.rtps_reliable_writer.high_watermark = piggybackEvery * 4;
21. qos->protocol.rtps_reliable_writer.low_watermark = piggybackEvery * 2;
22. qos->reliability.max_blocking_time = blockingTime;
23.
24. qos->protocol.rtps_reliable_writer.min_nack_response_delay.sec = 0;
25. qos->protocol.rtps_reliable_writer.min_nack_response_delay.nanosec = 0;
26.
27. qos->protocol.rtps_reliable_writer.max_nack_response_delay.sec = 0;
28. qos->protocol.rtps_reliable_writer.max_nack_response_delay.nanosec = 0;
29.
30. qos->protocol.rtps_reliable_writer.fast_heartbeat_period.sec = 0;
31. qos->protocol.rtps_reliable_writer.fast_heartbeat_period.nanosec =
32.     ` alertReaderWithinThisMs * 1000000;
33. qos->protocol.rtps_reliable_writer.max_heartbeat_retries = 7;
34.
35. // essentially turn off slow HB period
36. qos->protocol.rtps_reliable_writer.heartbeat_period.sec = 3600 * 24 * 7;

```

**Line 1** (Figure 32.14: QoS for a Periodic Reliable Writer on the previous page): This is the default setting for a writer, shown here strictly for clarity.

**Line 2** (Figure 32.14: QoS for a Periodic Reliable Writer on the previous page): Since we do not want any data lost, we set the History kind to KEEP\_ALL.

**Line 3** (Figure 32.14: QoS for a Periodic Reliable Writer on the previous page): This is the default setting for a writer, shown here strictly for clarity. Pushing will yield lower latency than pulling.

**Line 5-Line 7** (Figure 32.14: QoS for a Periodic Reliable Writer on the previous page): We do not use keys in this example, so there is only one instance.

**Line 9-Line 11** (Figure 32.14: QoS for a Periodic Reliable Writer on the previous page): Though a simplistic model of queue, this is consistent with the idea that the queue size should be proportional to the data rate and the worst case jitter in communication.

**Line 12** (Figure 32.14: QoS for a Periodic Reliable Writer on the previous page): Even though we have sized the queue according to the worst case, there is a possibility for saving some memory in the normal case. Here, we initially size the queue to be only half of the worst case, hoping that the worst case will not occur. When it does, *Connex*t will keep increasing the queue size as necessary to accommodate new DDS samples, until the maximum is reached. So when our optimistic initial queue size is breached, we will incur the penalty of dynamic memory allocation. Furthermore, you will wind up

using more memory, as the initially allocated memory will be orphaned (note: does not mean a memory leak or dangling pointer); if the initial queue size is  $M_i$  and the maximal queue size is  $M_m$ , where  $M_m = M_i * 2^n$ , the memory wasted in the worst case will be  $(M_m - 1) * \text{sizeof}(\text{DDS sample})$  bytes. Note that the memory allocation can be avoided by setting the initial queue size equal to its max value.

[Line 13-Line 14 \(Figure 32.14: QoS for a Periodic Reliable Writer on page 479\)](#): If there is only one instance, maximum DDS samples per instance is the same as maximum DDS samples allowed.

[Line 16-Line 18 \(Figure 32.14: QoS for a Periodic Reliable Writer on page 479\)](#): Since we are pushing out the data at a potentially rapid rate, the piggyback heartbeat will be useful in letting the reader know about any missing DDS samples. The **piggybackEvery** can be increased if the writer is writing at a fast rate, with the cost that more DDS samples will need to queue up for possible resend. That is, you can consider the piggyback heartbeat to be taking over one of the roles of the periodic heartbeat in the case of a push. So sending fewer DDS samples between piggyback heartbeats is akin to decreasing the fast heartbeat period seen in previous sections. Please note that we cannot express **piggybackEvery** directly as its own QoS, but indirectly through the maximum DDS samples.

[Line 20-Line 22 \(Figure 32.14: QoS for a Periodic Reliable Writer on page 479\)](#): If **piggybackEvery** was exactly identical to the fast heartbeat, there would be no need for fast heartbeat or the high watermark. But one of the important roles for the fast heartbeat period is to allow a writer to abandon inactive readers before the queue fills. If the high watermark is set equal to the queue size, the writer would not doubt the status of an unresponsive reader until the queue completely fills—blocking on the next write (up to **blockingTime**). By lowering the high watermark, you can control how vigilant a writer is about checking the status of unresponsive readers. By scaling the high watermark to **piggybackEvery**, the writer is expressing confidence that an alive reader will respond promptly within the time it would take a writer to send 4 times **piggybackEvery** DDS samples. If the reader does not delay the response too long, this would be a good assumption. Even if the writer estimated on the low side and does go into fast mode (suspecting that the reader has crashed) when a reader is temporarily unresponsive (e.g., when it is performing heavy computation for a few milliseconds), a response from the reader in question will resolve any doubt, and data delivery can continue uninterrupted. As the reader catches up to the writer and the queue level falls below the low watermark, the writer will pop out to the normal, relaxed mode.

[Line 24-Line 28 \(Figure 32.14: QoS for a Periodic Reliable Writer on page 479\)](#): When a reader is behind (including a reader whose Durability QoS is non-VOLATILE and therefore needs to catch up to the writer as soon as it is created), how quickly the writer responds to the reader's request will determine the catch-up rate. While a multicast writer (that is, a writer with multicast readers) may consider delaying for some time to take advantage of coalesced multicast packets. Keep in mind the OS delay resolution issue discussed in the previous section.

[Line 30-Line 33 \(Figure 32.14: QoS for a Periodic Reliable Writer on page 479\)](#): The fast heartbeat mechanism allows a writer to detect a crashed reader and move along with the remaining readers when a reader does not respond to any of the **max\_heartbeat\_retries** number of heartbeats sent at the **fast\_**

**heartbeat\_period** rate. So if you want a more cautious writer, decrease either numbers; conversely, increasing either number will result in a writer that is more reluctant to write-off an unresponsive reader.

[Line 35-Line 36 \(Figure 32.14: QoS for a Periodic Reliable Writer on page 479\)](#): Since this a periodic model, a separate periodic heartbeat to notify the writer’s status would seem unwarranted; the piggy-back heartbeat sent with DDS samples takes over that role.

[Figure 32.15: QoS for a Periodic Reliable Reader below](#) shows how to set the QoS for a matching reader, followed by a line-by-line explanation.

### Figure 32.15: QoS for a Periodic Reliable Reader

```

1. qos->reliability.kind = DDS_RELIABLE_RELIABILITY_QOS;
2.  qos->history.kind = DDS_KEEP_ALL_HISTORY_QOS;
3.  qos->resource_limits.initial_samples =
4.  qos->resource_limits.max_samples =
5.  qos->reader_resource_limits.max_samples_per_remote_writer =
6.    ((2*piggybackEvery - 1) + dataRateInHz * delayInMs / 1000);
7.
8.  //use these hard coded value until you use key
9.  qos->resource_limits.max_samples_per_instance =
10.     qos->resource_limits.max_samples;
11.  qos->resource_limits.initial_instances =
12.     qos->resource_limits.max_instances = 1;
13.
14.  qos->protocol.rtps_reliable_reader.min_heartbeat_response_delay.sec = 0;
15.  qos->protocol.rtps_reliable_reader.min_heartbeat_response_delay.nanosec = 0;
16.  qos->protocol.rtps_reliable_reader.max_heartbeat_response_delay.sec = 0;
17.  qos->protocol.rtps_reliable_reader.max_heartbeat_response_delay.nanosec = 0;

```

[Line 1-Line 2 \(Figure 32.15: QoS for a Periodic Reliable Reader above\)](#): Unlike a writer, the reader’s default reliability setting is best-effort, so reliability must be turned on. Since we don’t want to drop anything, we choose `KEEP_ALL` for the History QoS.

[Line 3-Line 6 \(Figure 32.15: QoS for a Periodic Reliable Reader above\)](#) Unlike the writer, the reader queue is sized not according to the jitter of the reader, but rather how many DDS samples you want to cache speculatively in case of a gap in sequence of DDS samples that the reader must recover. Remember that a reader will stop giving a sequence of DDS samples as soon as an unintended gap appears, because the definition of strict reliability includes in-order delivery. If the queue size were 1, the reader would have no choice but to drop all subsequent DDS samples received until the one being sought is recovered. *Connex* uses speculative caching, which minimizes the disruption caused by a few dropped DDS samples. Even for the same duration of disruption, the demand on reader queue size is greater if the writer will send more rapidly. In sizing the reader queue, we consider two factors that comprise the DDS sample recovery time:

- How long it takes a reader to request a resend to the writer.

The piggyback heartbeat tells a reader about the writer’s state. If only DDS samples between two piggybacked DDS samples are dropped, the reader must cache **iggybackEvery** DDS samples before asking the writer for resend. But if a piggybacked DDS sample is also lost, the reader will not get around to asking the writer until the next piggybacked DDS sample is received. Note that in this worst case calculation, we are ignoring stand-alone heartbeats (i.e., not piggybacked heartbeat from the writer). Of course, the reader may drop any number of heartbeats, including the stand-alone heartbeat; in this sense, there is no such thing as the absolute worst case—just reasonable worst case, where the probability of consecutive drops is acceptably low. For the majority of applications, even two consecutive drops is unlikely, in which case we need to cache at most  $(2 * \text{iggybackEvery} - 1)$  DDS samples before the reader will ask the writer to resend, assuming no delay (Line 14-Line 17, Figure 32.15: QoS for a Periodic Reliable Reader on the previous page).

- How long it takes for the writer to respond to the request.

Even ignoring the flight time of the resend request through the transport, the writer takes a finite time to respond to the repair request--mostly if the writer delays reply for multicast readers. In case of immediate response, the processing time on the writer end, as well as the flight time of the messages to and from the writer do not matter unless very larger data rate; that is, it is the product term that matters. In case the delay for multicast is random (that is, the minimum and the maximum delay are not equal), one would have to use the maximum delay to be conservative.

Line 8-Line 12 (Figure 32.15: QoS for a Periodic Reliable Reader on the previous page): Since we are not using keys, there is just one instance.

Line 14-Line 17 (Figure 32.15: QoS for a Periodic Reliable Reader on the previous page): If we are not using multicast, or the number of readers being fed by the writer, there is no reason to delay.

## 32.5 Auto Throttling for DataWriter Performance—Experimental Feature

*Auto Throttling* is an experimental feature that allows you to configure a *DataWriter* to automatically adjust its writing rate and send window size to provide the best latency/throughput tradeoff as system conditions change.

When *DataWriters* and *DataReaders* are configured to be reliable, DDS samples that did not reach the matched *DataReaders* for any reason (such as network drops or sample rejection by the *DataReader*) are repaired automatically by *Connex*. However, the repair path consumes bandwidth and increases latency. A high number of repaired DDS samples can reduce the throughput and increase the communication latency. With Auto Throttling, the number of repair DDS samples is reduced by using feedback provided by *DataReaders* in terms of ACK and NACK messages to adjust the *DataWriter's* write rate and send window size.

To configure Auto Throttling, use the following properties:

**dds.domain\_participant.auto\_throttle.enable:** Configures the *DomainParticipant* to gather internal measurements (during *DomainParticipant* creation) that are required for the Auto Throttle feature. This allows *DataWriters* belonging to this *DomainParticipant* to use the Auto Throttle feature. Default: false.

**dds.data\_writer.auto\_throttle.enable:** Enables automatic throttling in the *DataWriter* so it can automatically adjust the writing rate and the send window size; this minimizes the need for repair DDS samples and improves latency. Default: false.

**Note:** This property takes effect only in *DataWriters* that belong to a *DomainParticipant* that has set the property **dds.domain\_participant.auto\_throttle.enable** (described above) to true.

When Auto throttling is enabled, the size of the send window size is adjusted within the interval [**min\_send\_window\_size**, **max\_send\_window\_size**] configured in [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\)](#) on page 788.

# Chapter 33 Guaranteed Delivery of Data

Some application scenarios need to ensure that the information produced by certain producers is delivered to all the intended consumers. This chapter describes the mechanisms available in *Connex* to guarantee the delivery of information from producers to consumers such that the delivery is robust to many kinds of failures in the infrastructure, deployment, and even the producing/consuming applications themselves.

Guaranteed information delivery is not the same as protocol-level reliability (described in [Reliability Models for Sending Data \(Chapter 32 on page 446\)](#)) or information durability (described in [Mechanisms for Achieving Information Durability and Persistence \(Chapter 21 on page 288\)](#)). Guaranteed information delivery is an end-to-end application-level QoS, whereas the others are middleware-level QoS. There are significant differences between these two:

- With protocol-level reliability alone, the producing application knows that the information is received by the protocol layer on the consuming side. However the producing application cannot be certain that the consuming application read that information or was able to successfully understand and process it. The information could arrive in the consumer's protocol stack and be placed in the *DataReader* cache but the consuming application could either crash before it reads it from the cache, not read its cache, or read the cache using queries or conditions that prevent that particular DDS data sample from being accessed. Furthermore, the consuming application could access the DDS sample, but not be able to interpret its meaning or process it in the intended way.
- With information durability alone, there is no way to specify or characterize the intended consumers of the information. Therefore the infrastructure has no way to know when the information has been consumed by all the intended recipients. The information may be persisted such that it is not lost and is available to future applications, but the infrastructure and producing applications have no way to know that all the intended consumers have joined the system, received the information, and processed it successfully.

The guaranteed data-delivery mechanism provided in *Connex* overcomes the limitations described above by providing the following features:

- **Required subscriptions.** This feature provides a way to configure, identify and detect the applications that are intended to consume the information. See [31.13 Required Subscriptions on page 424](#).
- **Application-level acknowledgments.** This feature provides the means ensure that the information was successfully processed by the application-layer in a consumer application. See [31.12 Application Acknowledgment on page 418](#).
- **Durable subscriptions.** This feature leverages the RTI Persistence Service to persist DDS DDS samples intended for the required subscriptions such that they are delivered even if the originating application is not available. See [74.9 Configuring Durable Subscriptions in Persistence Service on page 1226](#).

These features used in combination with the mechanisms provided for Information Durability and Persistence (see [Mechanisms for Achieving Information Durability and Persistence \(Chapter 21 on page 288\)](#)) enable the creation of applications where the information delivery is guaranteed despite application and infrastructure failures. [33.4 Use Cases on page 490](#) describes various guaranteed-delivery scenarios and how to configure the applications to achieve them.

When implementing an application that needs guaranteed data delivery, we have to consider three key aspects:

Key Aspects to Consider	Related Features and QoS
Identifying the required consumers of information	Required subscriptions Durable subscriptions EntityName QoS policy Availability QoS policy
Ensuring the intended consumer applications process the data successfully	Application-level acknowledgment Acknowledgment by a quorum of required and durable subscriptions Reliability QoS policy (acknowledgment mode) Availability QoS policy
Ensuring information is available to late joining applications	Persistence Service Durable Subscriptions Durability QoS Durable Writer History

## 33.1 Identifying the Required Consumers of Information

The first step towards ensuring that information is processed by the intended consumers is the ability to specify and recognize those intended consumers. This is done using the *required subscriptions* feature ([31.13 Required Subscriptions on page 424](#)) configured via the [47.11 ENTITY\\_NAME QoS Policy \(DDS Extension\) on page 817](#) and [47.1 AVAILABILITY QoS Policy \(DDS Extension\) on page 769](#)).

*Connex* *DataReader* entities (as well as *DataWriter* and *DomainParticipant* entities) can have a *name* and a **role\_name**. These names are configured using the [47.11 ENTITY\\_NAME QoS Policy \(DDS Extension\) on page 817](#), which is propagated via DDS discovery and is available as part of the builtin-topic data for the Entity (see [Accessing Discovery Information through Built-In Topics \(Chapter 28 on page 359\)](#)).

The DDS *DomainParticipant*, *DataReader* and *DataWriter* entities created by RTI-provided applications and services, specifically services such as *RTI Persistence Service*, automatically configure the ENTITY\_NAME QoS policy according to their function. For example the *DataReaders* created by *RTI Persistence Service* have their **role\_name** set to “PERSISTENCE\_SERVICE”.

Unless explicitly set by the user, the *DomainParticipant*, *DataReader* and *DataWriter* entities created by end-user applications have their **name** and **role\_name** set to NULL. However applications may modify this using the [47.11 ENTITY\\_NAME QoS Policy \(DDS Extension\) on page 817](#).

*Connex* uses the **role\_name** of *DataReaders* to identify the consumer’s logical function. For this reason *Connex*’s *required subscriptions* feature relies on the **role\_name** to identify intended consumers of information. The use of the *DataReader*’s **role\_name** instead of the **name** is intentional. From the point of view of the information producer, the important thing is not the concrete *DataReader* (identified by its **name**, for example, “Logger123”) but rather its logical function in the system (identified by its **role\_name**, for example “LoggingService”).

A *DataWriter* that needs to ensure its information is delivered to all the intended consumers uses the [47.1 AVAILABILITY QoS Policy \(DDS Extension\) on page 769](#) to configure the role names of the consumers that must receive the information.

The AVAILABILITY QoS Policy set on a *DataWriter* lets an application configure the required consumers of the data produced by the *DataWriter*. The required consumers are specified in the **required\_matched\_endpoint\_groups** attribute within the AVAILABILITY QoS Policy. This attribute is a sequence of DDS *EndpointGroup* structures. Each *EndpointGroup* represents a required information consumer characterized by the consumer’s **role\_name** and **quorum\_count**. The **role\_name** identifies a logical consumer; the **quorum\_count** specifies the minimum number of consumers with that **role\_name** that must acknowledge the DDS sample before the *DataWriter* can consider it delivered to that required consumer.

For example, an application that wants to ensure data written by a *DataWriter* is delivered to at least two Logging Services and one Display Service would configure the *DataWriter*’s AVAILABILITY QoS Policy with a **required\_matched\_endpoint\_groups** consisting of two elements. The first element would specify a required consumer with the **role\_name** “LoggingService” and a **quorum\_count** of 2. The second element would specify a required consumer with the **role\_name** “DisplayService” and a **quorum\_count** of 1. Furthermore, the application would set the logging service *DataReader* ENTITY\_NAME policy to have a **role\_name** of “LoggingService” and similarly the display service *DataReader* ENTITY\_NAME policy to have the **role\_name** of “DisplayService.”

A *DataWriter* that has been configured with an AVAILABILITY QoS policy will not remove DDS samples from the *DataWriter* cache until they have been “delivered” to both the already-discovered *DataReaders* and the minimum number (**quorum\_count**) of *DataReaders* specified for each role. In particular, DDS samples will be retained by the *DataWriter* if the **quorum\_count** of matched *DataReaders* with a particular **role\_name** have not been discovered yet.

We used the word “delivered” in quotes above because the level of assurance a *DataWriter* has that a particular DDS sample has been delivered depends on the setting of the [47.21 RELIABILITY QoSPolicy on page 845](#). We discuss this next in [33.2 Ensuring Consumer Applications Process the Data Successfully below](#).

## 33.2 Ensuring Consumer Applications Process the Data Successfully

[33.1 Identifying the Required Consumers of Information on page 486](#) described mechanisms by which an application could configure who the required consumers of information are. This section is about the criteria, mechanisms, and assurance provided by *Connex*t to ensure consumers have the information delivered to them and process it in a successful manner.

RTI provides four levels of information delivery guarantee. You can set your desired level using the [47.21 RELIABILITY QoSPolicy on page 845](#). The levels are:

- **Best-effort, relying only on the underlying transport**The *DataWriter* considers the DDS sample delivered/acknowledged as soon as it is given to the transport to send to the *DataReader*'s destination. Therefore, the only guarantee is the one provided by the underlying transport itself. Note that even if the underlying transport is reliable (e.g., shared memory or TCP) the reliability is limited to the transport-level buffers. There is no guarantee that the DDS sample will arrive to the *DataReader* cache because after the transport delivers to the *DataReader*'s transport buffers, it is possible for the DDS sample to be dropped because it exceeds a resource limit, fails to deserialize properly, the receiving application crashes, etc.
- **Reliable with protocol acknowledgment**The DDS-RTPS reliability protocol used by *Connex*t provides acknowledgment at the RTPS protocol level: a *DataReader* will acknowledge it has deserialized the DDS sample correctly and stored it in the *DataReader*'s cache. However, there is no guarantee the application actually processed the DDS sample. The application might crash before processing the DDS sample, or it might simply fail to read it from the cache.
- **Reliable with Application Acknowledgment (Auto)**Application Acknowledgment in Auto mode causes *Connex*t to send an additional application-level acknowledgment (above and beyond the RTPS protocol level acknowledgment) after the consuming application has read the DDS sample from the *DataReader* cache and the application has subsequently called the *DataReader*'s **return\_loan()** operation (see [41.2 Loaning and Returning Data and SampleInfo Sequences on page 664](#)) for that DDS sample. This mode guarantees that the application has fully read the DDS sample all the way until it indicates it is done with it. However it does not provide a guarantee that the application was able to successfully interpret or process the DDS sample. For example,

the DDS sample could be a command to execute a certain action and the application may read the DDS sample and not understand the command or may not be able to execute the action.

- **Reliable with Application Acknowledgment (Explicit)** Application Acknowledgment in Explicit mode causes *Connex*t to send an application-level acknowledgment only after the consuming application has read the DDS sample from the *DataReader* cache and subsequently called the *DataReader*'s `acknowledge_sample()` operation (see [41.4 Acknowledging DDS Samples on page 674](#)) for that DDS sample. This mode guarantees that the application has fully read the DDS sample and completed operating on it as indicated by explicitly calling `acknowledge_sample()`. In contrast with the Auto mode described above, the application can delay the acknowledgment of the DDS sample beyond the time it holds onto the data buffers, allowing it to be process in a more flexible manner. Similar to the Auto mode, it does not provide a guarantee that the application was able to successfully interpret or process the DDS sample. For example, the DDS sample could be a command to execute a certain action and the application may read the DDS sample and not understand the command or may not be able to execute the action. Applications that need guarantees that the data was successfully processed and interpreted should use a request-reply interaction (see [Chapter 61 Request-Reply on page 1146](#)).

### 33.3 Ensuring Information is Available to Late-Joining Applications

The third aspect of guaranteed data delivery addresses situations where the application needs to ensure that the information produced by a particular *DataWriter* is available to *DataReaders* that join the system after the data was produced. The need for data delivery may even extend beyond the lifetime of the producing application; that is, it may be required that the information is delivered to applications that join the system after the producing application has left the system.

*Connex*t provides four mechanisms to handle these scenarios:

- **The DDS Durability QoS Policy.** The [47.9 DURABILITY QoS Policy on page 809](#) specifies whether DDS samples should be available to late joiners. The policy is set on the *DataWriter* and the *DataReader* and supports four kinds: VOLATILE, TRANSIENT\_LOCAL, TRANSIENT, or PERSISTENT. If the *DataWriter*'s Durability QoS policy is set to VOLATILE kind, the *DataWriter*'s DDS samples will not be made available to any late joiners. If the *DataWriter*'s policy kind is set to TRANSIENT\_LOCAL, TRANSIENT, or PERSISTENT, the DDS samples will be made available for late-joining *DataReaders* who also set their DURABILITY QoS policy kind to something other than VOLATILE.
- **Durable Writer History.** A *DataWriter* configured with a DURABILITY QoS policy kind other than VOLATILE keeps its data in a local cache so that it is available when the late-joining application appears. The data is maintained in the *DataWriter*'s cache until it is considered to be no longer needed. The precise criteria depends on the configuration of additional QoS policies such as [47.14 LIFESPAN QoS Policy on page 824](#), [47.12 HISTORY QoS Policy on page 818](#), [47.22 RESOURCE\\_LIMITS QoS Policy on page 850](#), etc. For the purposes of guaranteeing information delivery it is important to note that the *DataWriter*'s cache can be configured to be a memory

cache or a durable (disk-based) cache. A memory cache will not survive an application restart. However, a durable (disk-based) cache can survive the restart of the producing application. The use of a durable writer history, including the use of an external ODBC database as a cache, is described in [21.3 Durable Writer History on page 295](#).

- **RTI Persistence Service.** This service allows the information produced by a *DataWriter* to survive beyond the lifetime of the producing application. *Persistence Service* is a stand-alone application that runs on many supported platforms. This service complies with the Persistent Profile of the OMG DDS specification. The service uses DDS to subscribe to the *DataWriters* that specify a [47.9 DURABILITY QosPolicy on page 809](#) kind of TRANSIENT or PERSISTENT. *Persistence Service* receives the data from those *DataWriters*, stores the data in its internal caches, and makes the data available via *DataWriters* (which are automatically created by *Persistence Service*) to late-joining *DataReaders* that specify a Durability kind of TRANSIENT or PERSISTENT. *Persistence Service* can operate as a relay for the information from the original writer, preserving the **source\_timestamp** of the data, as well as the original DDS sample virtual writer GUID (see [21.5.1 RTI Persistence Service on page 305](#)). In addition, you can configure *Persistence Service* itself to use a memory-based cache or a durable (disk-based or database-based) cache. See [74.6 Configuring Persistent Storage on page 1216](#). Configuration of redundant and load-balanced persistence services is also supported.
- **Durable Subscriptions.** This is a *Persistence Service* configuration setting that allows configuration of the required subscriptions ([33.1 Identifying the Required Consumers of Information on page 486](#)) for the data stored by *Persistence Service* ([31.14 Managing Instances \(Working with Keyed Data Types\) on page 425](#)). Configuring required subscriptions for *Persistence Service* ensures that the service will store the DDS samples until they have been delivered to the configured number (**quorum\_count**) of *DataReaders* that have each of the specified roles.

## 33.4 Use Cases

In each of the scenarios below, we assume both the *DataWriter* and *DataReader* are configured for strict reliability (RELIABLE ReliabilityQosPolicyKind and KEEP\_ALL HistoryQosPolicyKind, see [32.4.3 Controlling Queue Depth with the History QosPolicy on page 461](#)). As a result, when the *DataWriter's* cache is full of unacknowledged DDS samples, the **write()** operation will block until DDS samples are acknowledged by all the intended consumers.

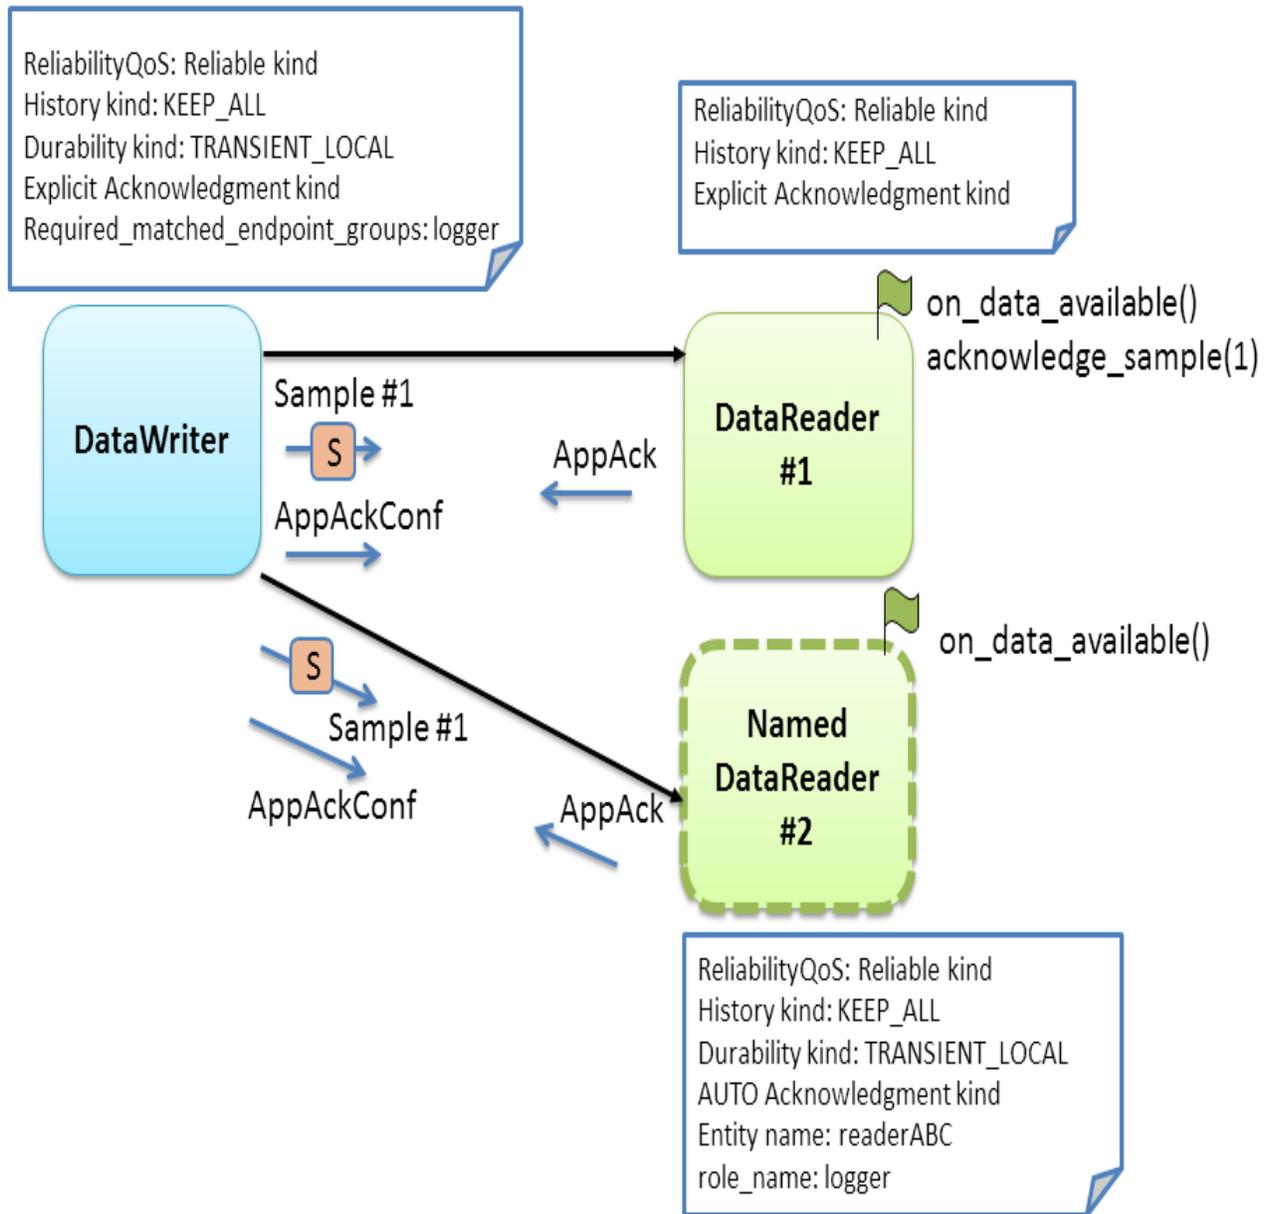

### 33.4.1 Scenario 1: Guaranteed Delivery to a-priori Known Subscribers

A common use case is to guarantee delivery to a set of known subscribers. These subscribers may be already running and have been discovered, they may be temporarily non-responsive, or it could be that some of those subscribers are still not present in the system. See [Figure 33.1: Guaranteed Delivery Scenario 1 on the next page](#).

To guarantee delivery, the list of required subscribers should be configured using the [47.1 AVAILABILITY QosPolicy \(DDS Extension\) on page 769](#) on the *DataWriters* to specify the **role\_**

**name** and **quorum\_count** for each required subscription. Similarly the [47.11 ENTITY\\_NAME QoS Policy \(DDS Extension\)](#) on page 817 should be used on the *DataReaders* to specify their **role\_name**. In addition we use [31.12 Application Acknowledgment](#) on page 418 to guarantee the DDS sample was delivered and processed by the *DataReader*.

Figure 33.1: Guaranteed Delivery Scenario 1

The *DataWriter's* and *DataReader's* RELIABILITY QoS Policy can be configured for either AUTO or EXPLICIT application acknowledgment kind. As the *DataWriter* publishes the DDS sample, it will

await acknowledgment from the *DataReader* (through the protocol-level acknowledgment) and from the subscriber application (through the additional application-level acknowledgment). The *DataWriter* will only consider the DDS sample acknowledged when it has been acknowledged by all discovered active *DataReaders* and also by the **quorum\_count** of each required subscription.

In this specific scenario, *DataReader* #1 is configured for EXPLICIT application acknowledgment. After reading and processing the DDS sample, the subscribing application calls **acknowledge\_sample()** or **acknowledge\_all()** (see [41.4 Acknowledging DDS Samples on page 674](#)). As a result, *Connex*t will send an application-level acknowledgment to the *DataWriter*, which will in its turn confirm the acknowledgment.

If the DDS sample was lost in transit, the reliability protocol will repair the DDS sample. Since it has not been acknowledged, it remains available in the writer's queue to be automatically resent by *Connex*t. The DDS sample will remain available until acknowledged by the application. If the subscribing application crashes while processing the DDS sample and restarts, *Connex*t will repair the unacknowledged DDS sample. DDS samples which already been processed and acknowledged will not be resent.

In this scenario, *DataReader* #2 may be a late joiner. When it starts up, because it is configured with TRANSIENT\_LOCAL Durability, the reliability protocol will re-send the DDS samples previously sent by the writer. These DDS samples were considered unacknowledged by the *DataWriter* because they had not been confirmed yet by the required subscription (identified by its **role\_name**: 'logger').

*DataReader* #2 does not explicitly acknowledge the DDS samples it reads. It is configured to use AUTO application acknowledgment, which will automatically acknowledge DDS samples that have been read or taken after the application calls the *DataReader* *return\_loan* operation.

This configuration works well for situations where the *DataReader* may not be immediately available or may restart. However, this configuration does not provide any guarantee if the *DataWriter* restarts. When the *DataWriter* restarts, DDS samples previously unacknowledged are lost and will no longer be available to any late joining *DataReaders*.

### 33.4.2 Scenario 2: Surviving a Writer Restart when Delivering DDS Samples to a priori Known Subscribers

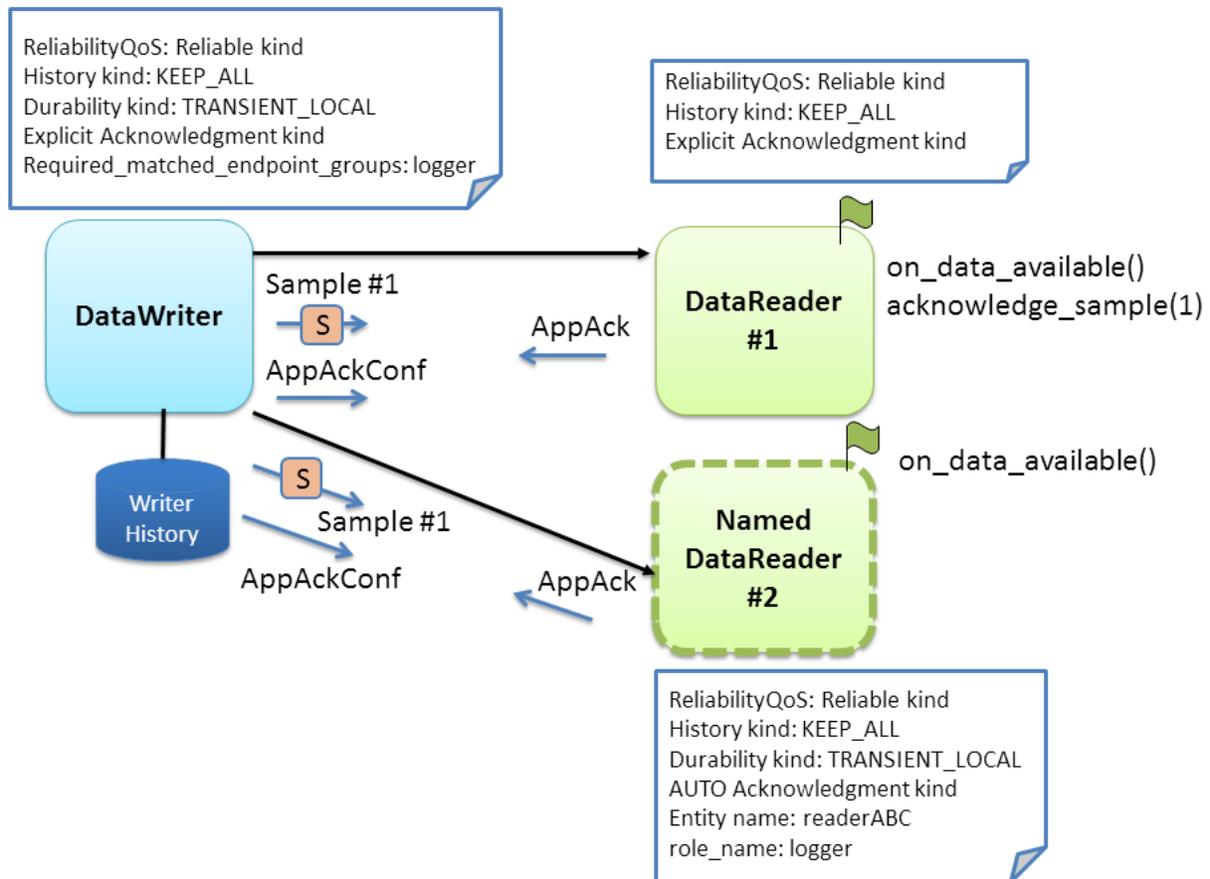

Scenario 1 describes a use case where DDS samples are delivered to a list of a priori known subscribers. In that scenario, *Connex*t will deliver DDS samples to the late-joining or restarting subscriber. However, if the producer is re-started the DDS samples it had written will no longer be available to future subscribers.

To handle a situation where the producing application is restarted, we will use the [21.3 Durable Writer History on page 295](#) feature. See [Figure 33.2: Guaranteed Delivery Scenario 2 on the next page](#).

A *DataWriter* can be configured to maintain its data and state in durable storage. This configuration is done using the PROPERTY QoS policy as described in [21.3.2 How To Configure Durable Writer](#)

[History on page 297](#).. With this configuration the DDS data samples written by the *DataWriter* and any necessary internal state is persisted by the *DataWriter* into durable storage. As a result, when the *DataWriter* restarts, DDS samples which had not been acknowledged by the set of required subscriptions will be resent and late-joining *DataReaders* specifying DURABILITY kind different from VOLATILE will receive the previously-written DDS samples.

Figure 33.2: Guaranteed Delivery Scenario 2

### 33.4.3 Scenario 3: Delivery Guaranteed by Persistence Service (Store and Forward) to a priori Known Subscribers

Previous scenarios illustrated that using the DURABILITY, RELIABILITY, and AVAILABILITY QoS policies we can ensure that as long as the *DataWriter* is present in the system, DDS samples written by a *DataWriter* will be delivered to the intended consumers. The use of the durable writer history in the previous scenario extended this guarantee even in the presence of a restart of the application writing the data.

This scenario addresses the situation where the originating application that produced the data is no longer available. For example, the network could have become partitioned, the application could have been terminated, it could have crashed and not have been restarted, etc.

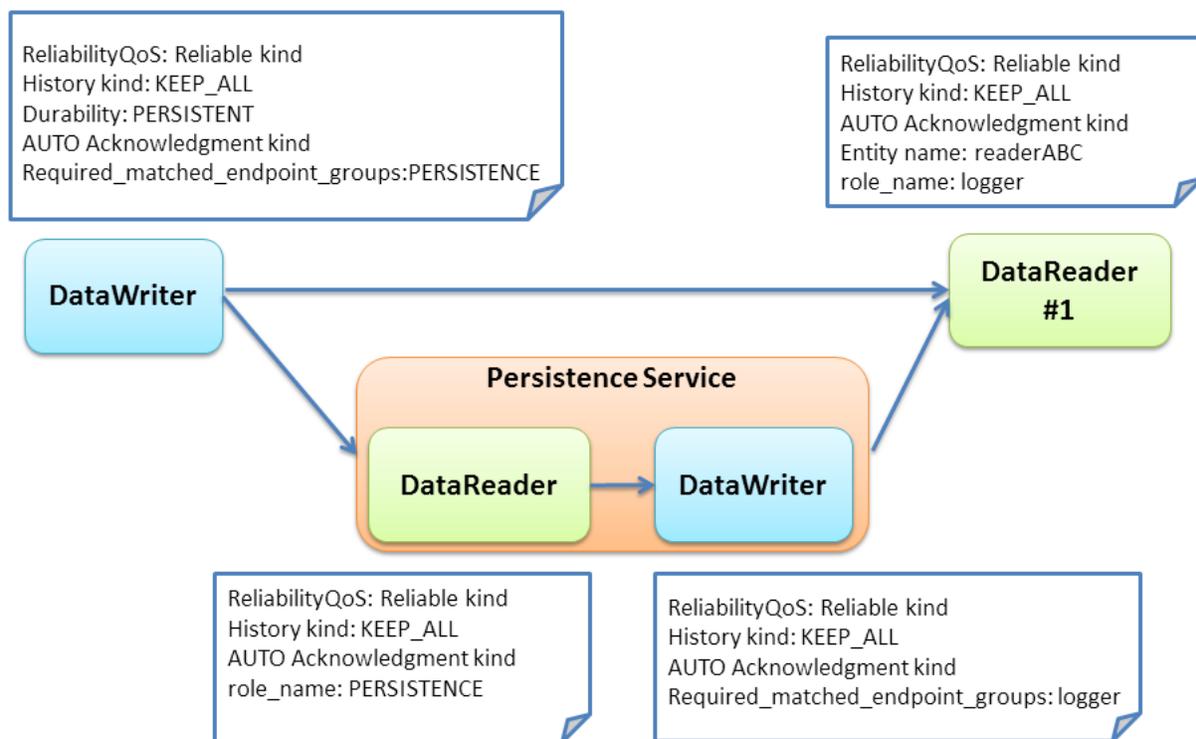

In order to deliver data to applications that appear after the producing application is no longer available on the network it is necessary to have another service that stores those DDS samples and delivers them. This is the purpose of the *RTI Persistence Service*.

*Persistence Service* can be configured to automatically discover *DataWriters* that specify a DURABILITY QoS with **kind** TRANSIENT or PERSISTENT and automatically create pairs (*DataReader*, *DataWriter*) that receive and store that information (see [Introduction to RTI Persistence Service \(Chapter 73 on page 1206\)](#)).

All *DataReaders* created by the *RTI Persistence Service* have the ENTITY\_QOS policy set with the **role\_name** of “PERSISTENCE\_SERVICE”. This allows an application to specify *Persistence Service* as one of the required subscriptions for its *DataWriters*.

In this third scenario, we take advantage of this capability to configure the *DataWriter* to have the RTI *Persistence Service* as a required subscription. See [Figure 33.3: Guaranteed Delivery Scenario 3](#) below.

**Figure 33.3: Guaranteed Delivery Scenario 3**

The RTI *Persistence Service* can also have its *DataWriters* configured with required subscriptions. This feature is known as *Persistence Service* “durable subscriptions”. *DataReader #1* is pre configured in *Persistence Service* as a Durable Subscription. (Alternatively, *DataReader #1* could have registered itself dynamically as Durable Subscription using the *DomainParticipant register\_durable\_subscription()* operation).

We also configure the RELIABILITY QoS policy setting of the AcknowledgmentKind to APPLICATION\_AUTO\_ACKNOWLEDGMENT\_MODE in order to ensure DDS samples are stored in the *Persistence Service* and properly processed on the consuming application prior to them being removed from the *DataWriter* cache.

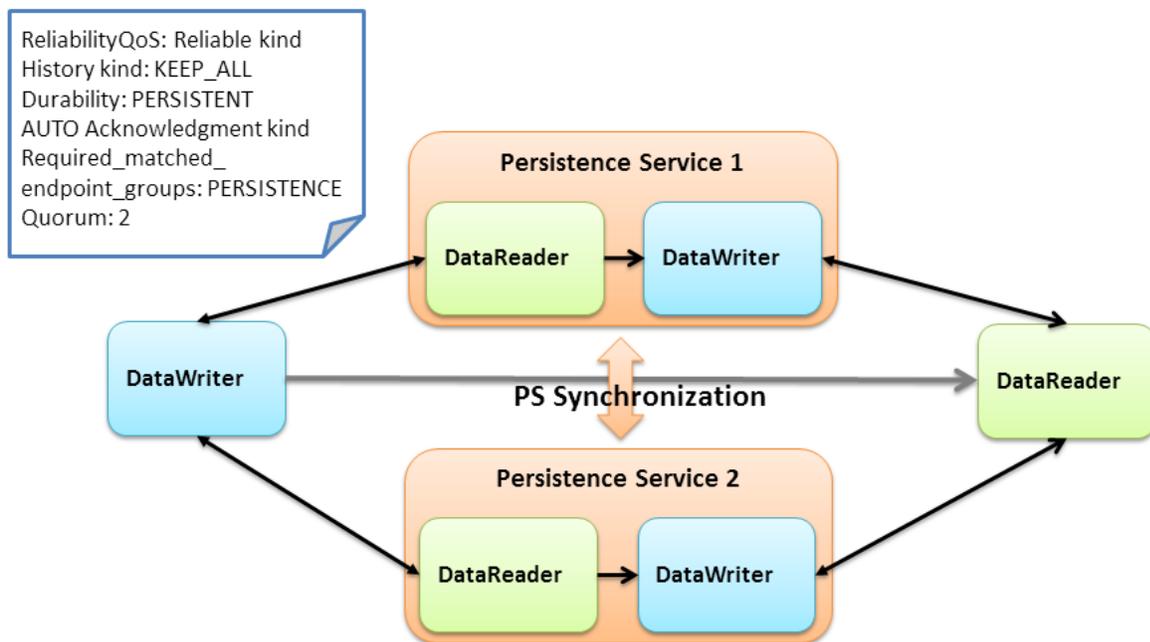

With this configuration in place the *DataWriter* will deliver DDS samples to the *DataReader* and to the *Persistence Service* reliably and wait for the Application Acknowledgment from both. Delivery of DDS samples to *DataReader* #1 and the *Persistence Service* occurs concurrently. The *Persistence Service* in turn takes responsibility to deliver the DDS samples to the configured “logger” durable subscription. If the original publisher is no longer available, DDS samples can still be delivered by the *Persistence Service* to *DataReader* #1 and any other late-joining *DataReaders*.

When *DataReader* #1 acknowledges the DDS sample through an application-acknowledgment message, both the original *DataWriter* and *Persistence Service* will receive the application-acknowledgment. *Connext* takes advantage of this to reduce or eliminate delivery of duplicate DDS samples, that is, the *Persistence Service* can notice that *DataReader* #1 has acknowledged a DDS sample and refrain from separately sending the same DDS sample to *DataReader* #1.

### 33.4.3.1 Variation: Using Redundant Persistence Services

Using a single Persistence Service to guarantee delivery can still raise concerns about having the Persistence Service as a single point of failure. To provide a level of added redundancy, the publisher may be configured to await acknowledgment from a quorum of multiple persistence services (**role\_name** remains PERSISTENCE). Using this configuration we can achieve higher levels of redundancy

Figure 33.4: Guaranteed Delivery Scenario 3 with Redundant Persistence Service

The RTI *Persistence Services* will automatically share information to keep each other synchronized. This includes both the data and also the information on the durable subscriptions. That is, when a Persistence Service discovers a durable subscription, information about durable subscriptions is automatically replicated and synchronized among persistence services (CITE: New section to be written in Persistence Service Chapter).

#### 33.4.3.2 Variation: Using Load-Balanced Persistent Services

The *Persistence Service* will store DDS samples on behalf of many DataWriters and, depending on the configuration, it might write those DDS samples to a database or to disk. For this reason the *Persistence Service* may become a bottleneck in systems with high durable DDS sample throughput.

It is possible to run multiple instances of the *Persistence Service* in a manner where each is only responsible for the guaranteed delivery of certain subset of the durable data being published. These *Persistence Service* can also be run different computers and in this manner achieve much higher throughput. For example, depending on the hardware, using typical hard-drives a single *Persistence Service* may be able to store only 30000 DDS samples per second. By running 10 persistence services in 10 different computers we would be able to handle storing 10 times that system-wide, that is, 300000 DDS samples per second.

The data to be persisted can be partitioned among the persistence services by specifying different Topics to be persisted by each *Persistence Service*. If a single Topic has more data that can be handled by a single *Persistence Service* it is also possible to specify a content-filter so that only the data within that Topic that matches the filter will be stored by the *Persistence Service*. For example assume the Topic being persisted has an member named “x” of type float. It is possible to configure two *Persistence Services* one with the filter “x>10”, and the other “x <=10”, such that each only stores a subject of the data published on the Topic. See also: [74.9 Configuring Durable Subscriptions in Persistence Service on page 1226](#).

# Chapter 34 Sending Large Data

This section describes the capabilities offered by *Connex* to allow sending and receiving large data samples. In this section, “large data” refers to samples with a large serialized size, usually on the order of MBs, such as video frame samples.

The definition of “large data” in this chapter contrasts with other definitions of large data in this manual:

- In [46.1 ASYNCHRONOUS\\_PUBLISHER QosPolicy \(DDS Extension\) on page 740](#), “large data” is defined as data that cannot be sent as a single packet by a transport. The concept of large data in this section is decoupled from the maximum message size of the underlying transport, although these two things are related: samples with a size in the order of MBs will usually be greater than the underlying transport’s maximum message size.
- In [Chapter 20 Sample and Instance Memory Management on page 271](#), “large data” refers to types whose samples have a large maximum serialized size independently of the actual serialized size of the samples sent on the wire. This contrasts with the definition of “large data” in this section, which refers to samples with a large serialized size.

*Connex* offers the following solutions to optimize the sending and receiving of large data:

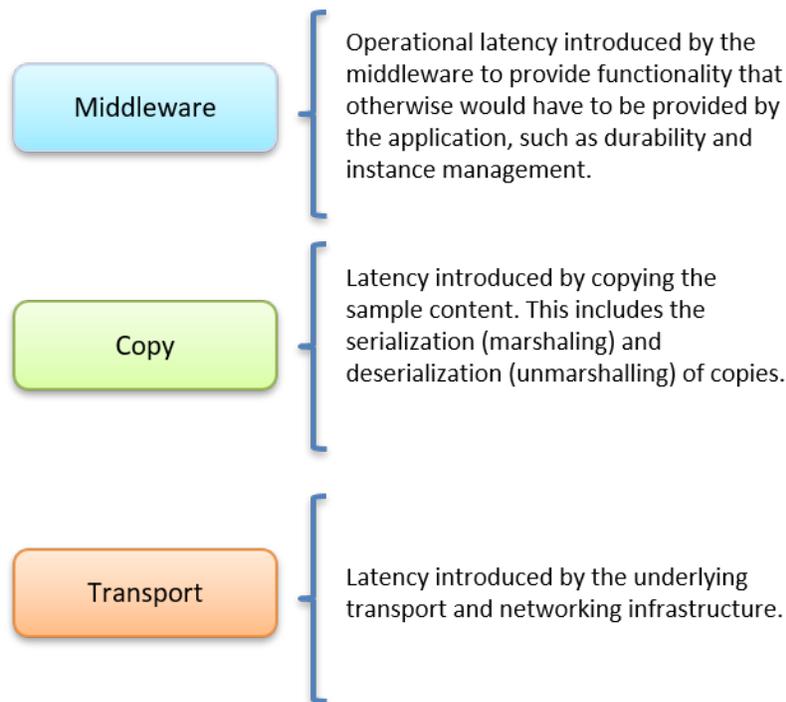

- Reducing latency using either or both of the following to reduce the number of copies produced by the middleware; see [34.1 Reducing Latency on the next page](#):
  - *RTI FlatData™ language binding*; see [34.1.4 FlatData Language Binding on page 503](#)
  - Zero Copy transfer over shared memory; see [34.1.5 Zero Copy Transfer Over Shared Memory on page 516](#)

- Reducing bandwidth usage by compressing samples with a set of standard compression algorithms; see [47.3 DATA\\_REPRESENTATION QosPolicy on page 780](#)

## 34.1 Reducing Latency

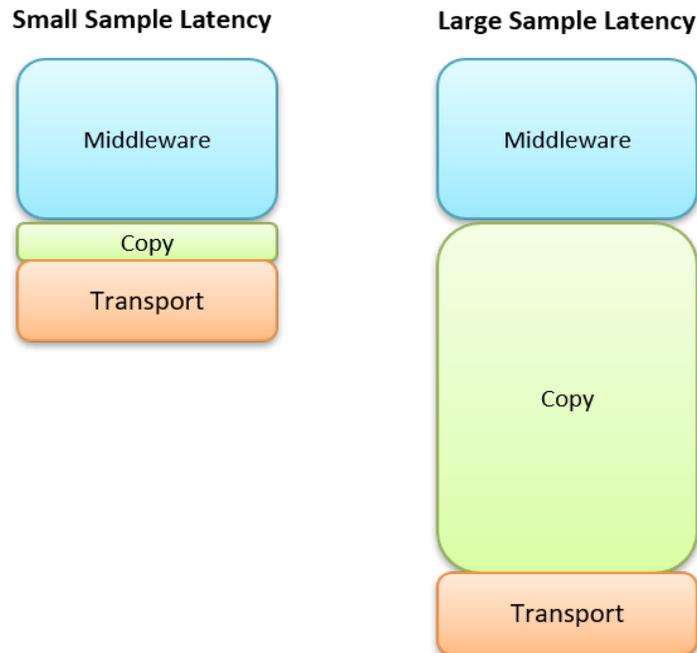

One of the main considerations when sending large samples is latency. When using *Connex*, and in general any connectivity framework, sample latency has three components: middleware, copy, and transport (see [Figure 34.1: Basic Components of Latency](#) below).

Figure 34.1: Basic Components of Latency

When *Connex* is used to send small data samples, such as temperature readings, the weight of the copy component in the total sample latency is small. But when samples are large, the weight of the copy component becomes considerable. (See [Figure 34.2: Copy Components Compared on the next page.](#))

Figure 34.2: Copy Components Compared

Therefore, reducing the number of copies made by the middleware or network infrastructure when publishing and receiving large samples becomes critical. Two features allow reducing the number of sample copies and consequently the transmission latency: *Zero Copy transfer over shared memory* and *FlatData language binding*. These two features can be used individually or in combination.

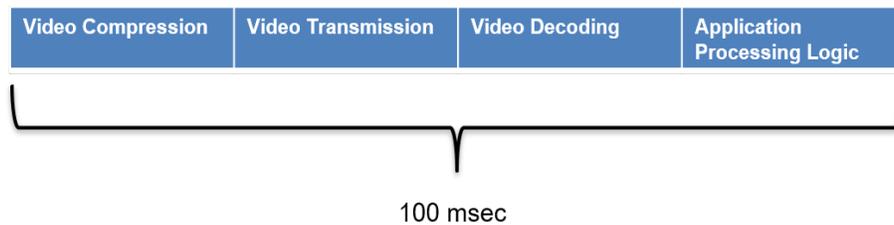

**Important:** “Large samples” in this context refers to samples with a large serialized size, usually on the order of MBs, such as video frame samples. If you implement FlatData language binding or Zero Copy transfer over shared memory with data smaller than this, you may not see significant difference in latency or even pay a penalty in latency.

### 34.1.1 Use Cases

Zero Copy transfer over shared memory and FlatData language binding are recommended when your strict latency requirements cannot be met by regular C/C++ language binding (which defines the in-memory representation of a type), and the UDP and shared memory transports. For example, video applications such as video conferencing, video surveillance, or computer vision usually have strict latency requirements, especially if the video signal is used to do control. Consider, for instance, a latency requirement of less than 100 milliseconds. This latency must account for different components such as:

- Video compression
- Video decoding

- Transmission
- Image scaling
- Application processing logic

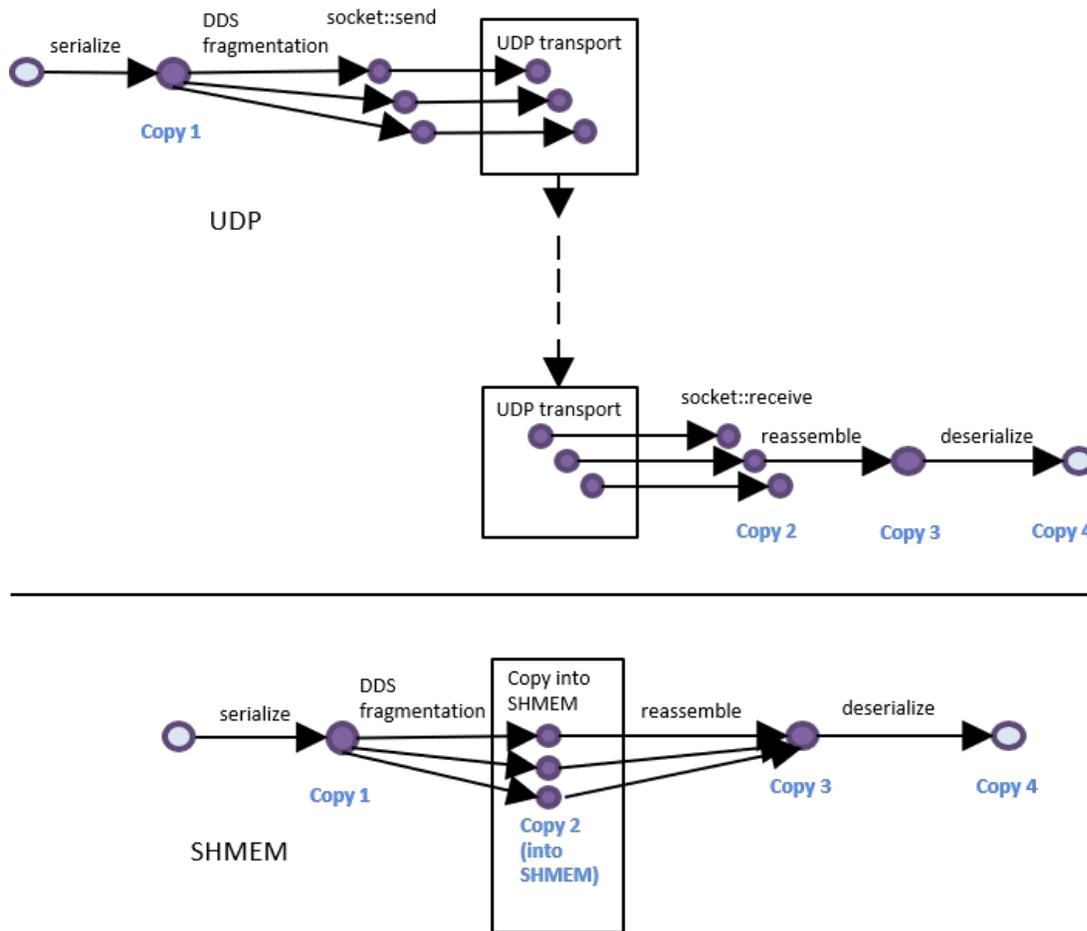

To keep latency to a minimum for large data samples, reduce the number of copies made by the middleware or network infrastructure by using FlatData language binding, Zero Copy transfer over shared memory, or both.

### 34.1.2 Copies in the Middleware Memory Space

Figure 34.3: [Number of Copies Out-of-the-Box on the next page](#) shows how many times *Connex* may copy a large sample sent over UDP or shared memory. The diagram assumes that the samples have to be fragmented by the middleware (via DDS fragmentation) because their serialized size is greater than the underlying transport MTU (maximum transmission unit), which can be configured by setting `message_size_max` in the transport properties (see [Chapter 51 UDPv4, UDPv6, and Shared Memory Transport Plugins on page 955](#)). Note that these are copies in the middleware memory space—the operating system network stack may make additional copies.

Figure 34.3: Number of Copies Out-of-the-Box

For both UDP and shared memory (SHMEM), the copies are as follows, out of the box:

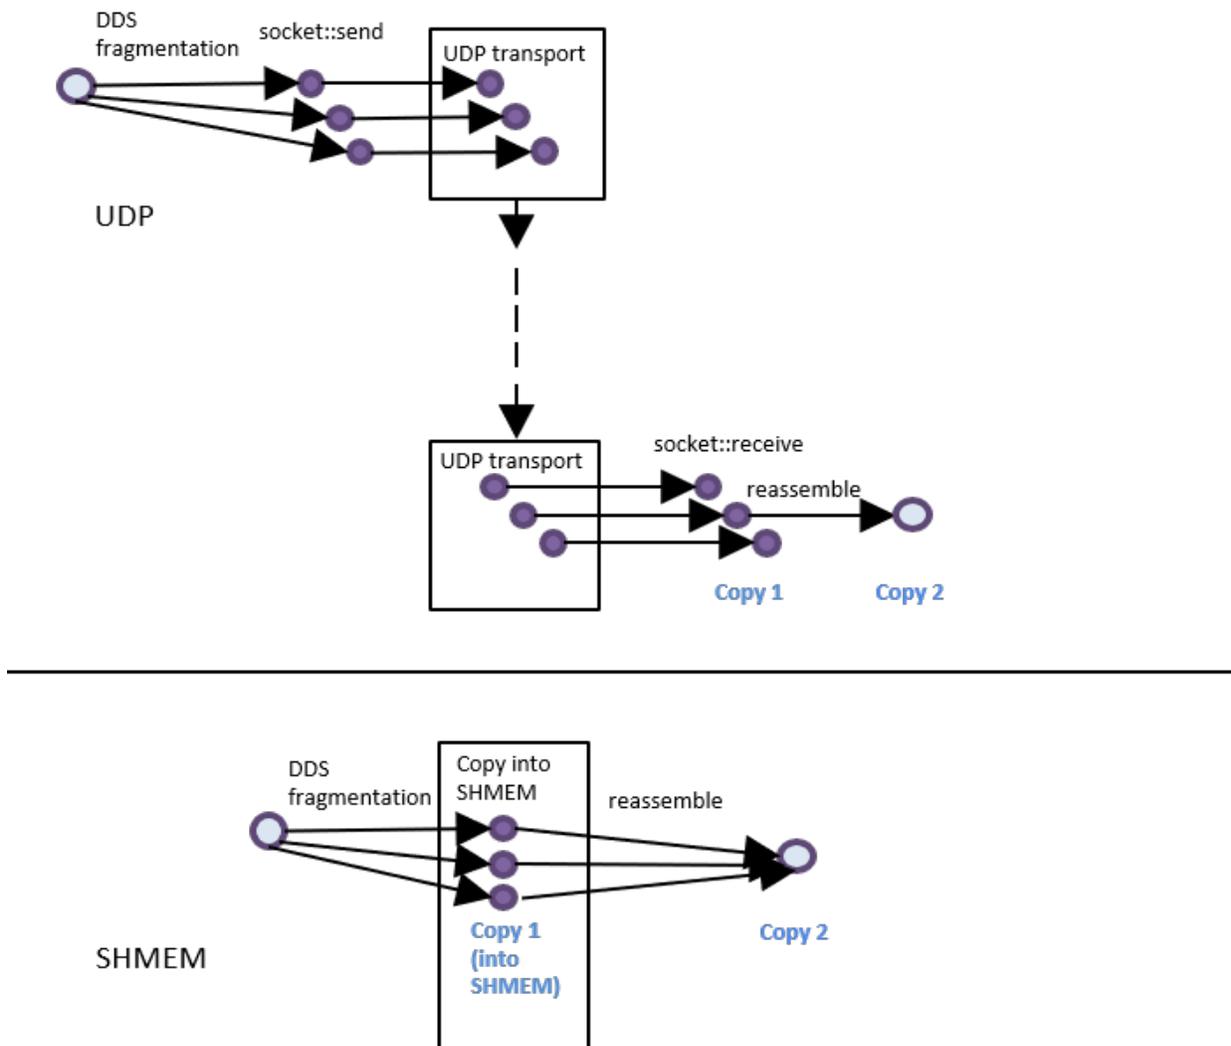

1. Copy 1 is the serialization copy. *Connex* calls **TypePlugin::serialize** to convert the in-memory representation of a sample, such as a C++ object, into a data representation, called a wire representation, with a format suitable for storage or transmission.

After a sample is serialized, it is sent to the subscribing application using one or more of the available transports. When the underlying transport maximum message size is smaller than the serialized size of the sample, the sample must be fragmented. The fragmentation process does not require any extra copy. Fragments refer directly to offsets in the serialization buffer.

**Note:** The transport maximum message size can be configured using the property **dds.transport.UDPv4.builtin.parent.message\_size\_max** for UDPv4 and **dds.transport.shmem.builtin.parent.message\_size\_max** for SHMEM. There are equivalent properties for other transports, such as TCPv4 and UDPv6.

2. Copy 2: For SHMEM, the sample fragments that live in the local memory space of the publishing process have to be copied into the shared memory segment from which the subscribing application will read them. For UDP, the call to the socket receive operation copies the fragments.
3. Copy 3: After they are received, the sample fragments are reassembled into a single buffer.
4. Copy 4 is the deserialization copy. Connex calls **TypePlugin::deserialize** to convert the wire memory representation of a sample into its in-memory representation, such as a C++ object.

Figure 34.4: Number of Copies Using FlatData Language Binding

FlatData is a language binding in which the in-memory representation of a sample matches the wire representation. Therefore, the cost of serialization/deserialization is zero. You can directly access the serialized data without deserializing it first. When using FlatData language binding, Copy 1 and Copy 4 in [Figure 34.3: Number of Copies Out-of-the-Box on the previous page](#) are removed for both UDP and

SHMEM communications. See [Figure 34.4: Number of Copies Using FlatData Language Binding on the previous page](#).

### 34.1.3 Choosing between FlatData Language Binding and Zero Copy Transfer over Shared Memory

Whether to use Zero Copy transfer over shared memory or FlatData language binding, or both, depends on whether the *DataReaders* run on the same host as the *DataWriters*, on different hosts, or a combination of both. It also depends on the definition of the type. Zero Copy transfer over shared memory requires the FlatData language binding when the type is variable-size. The following table summarizes how to choose between these features:

**Table 34.1 Zero Copy Transfer Over Shared Memory vs. FlatData Language Binding**

	Readers and writers run on same host	Readers and writers run on different hosts	Some readers/writers run on same host, some on different hosts
Fixed-size types	Use Zero Copy	Use FlatData	Use both Zero Copy and FlatData
Variable-size types	Use both Zero Copy and FlatData	Use FlatData	Use both Zero Copy and FlatData

In summary, for *DataReaders* running on the same host as the *DataWriter*, the *DataWriter* can take advantage of Zero Copy transfer over shared memory. For *DataReaders* running on a different host, the *DataWriter* won't use Zero Copy transfer over shared memory, but can benefit from FlatData language binding. Therefore, when you have writers and readers running on the same and different hosts, it is recommended to use both Zero Copy transfer over shared memory and FlatData language binding, and let the *DataWriter* use the correct option for each *DataReader*.

For more information, see [34.1.4 FlatData Language Binding below](#) and [34.1.5 Zero Copy Transfer Over Shared Memory on page 516](#).

### 34.1.4 FlatData Language Binding

FlatData language binding offers the following benefits:

- Reduced number of copies: from four to two for both SHMEM and UDP transports (see [Figure 34.4: Number of Copies Using FlatData Language Binding on the previous page](#)), because there is no need to serialize and deserialize a sample.
- Reduced memory consumption and CPU load, due to reduced data copying.
- Improved latency for large data samples.

### 34.1.4.1 FlatData Representation

When you create a FlatData sample (see [34.1.4.2 Programming with FlatData Language Binding on page 506](#)), the in-memory representation for the sample buffer is XCDR encoding version 2 (XCDR2), using the endianness of the host where the sample is created to populate the buffer. The use of the host platform endianness allows fast access to the sample content, because the setters and getters do not have to change the endianness.

If you use a *DataReader* to read a FlatData sample that was received from a *DataWriter* running on a platform with a different endianness, however, direct access to the sample content is not possible, making the subscribing application less performant.

**Note:** Because the in-memory representation of a FlatData sample is XCDR2 and older versions of *Connex* use encoding version 1 (XCDR), applications using the FlatData language binding will not communicate with older versions of *Connex*. See *Choosing the Right Data Representation*, in the *Data Representation* chapter of the [RTI Connex Core Libraries Extensible Types Guide](#).

### 34.1.4.2 Using FlatData Language Binding

The following sections contain more information about using FlatData language binding:

- [34.1.4.2.1 Selecting FlatData Language Binding below](#)
- [34.1.4.2.2 Programming with FlatData Language Binding on page 506](#)
- [34.1.4.2.3 Languages Supported by FlatData Language Binding on page 515](#)
- [34.1.4.2.4 Interactions with RTI Security Plugins and Compression on page 515](#)
- [34.1.4.2.5 Notes on Batching on page 516](#)

For examples of FlatData language binding and Zero Copy transfer over shared memory, including example code, see <https://community.rti.com/kb/flatdata-and-zerocopy-examples>.

#### 34.1.4.2.1 Selecting FlatData Language Binding

To select FlatData as the language binding of a type, annotate it with `@language_binding(FLAT_DATA)`. (See [17.3.9.9 The @language\\_binding Annotation on page 205](#).)

For example, consider a surveillance application in which high-definition (HD) video signal is published and subscribed to. The application publishes a *Topic* of the type **CameraImage**. This is the IDL:

```
enum Format {
    RGB,
    HSV,
    YUV
};

@final
```

```

@language_binding(FLAT_DATA)
struct Resolution {
    int32 height;
    int32 width;
};

@final
@language_binding(FLAT_DATA)
struct Pixel {
    octet red;
    octet green;
    octet blue;
};

const int32 MAX_IMAGE_SIZE = 8294400;

@mutable
@language_binding(FLAT_DATA)
struct CameraImage {
    string<128> source;
    Format format;
    Resolution resolution;
    sequence<Pixel, MAX_IMAGE_SIZE> pixels;
};

```

The language binding annotation supports two values: `FLAT_DATA` and `PLAIN` (default). `PLAIN` refers to the regular in-memory representation, where an IDL struct maps to a C++ class or C struct.

There are some restrictions regarding the kinds of structures, value types, and unions to which the FlatData language binding can be applied.

For final types, the FlatData language binding can be applied only to fixed-size types. A fixed-size type is a type whose wire representation always has the same size. This includes primitive types, arrays of fixed-size types, and structs containing only members of fix-size types. Unions are not fixed-size types.<sup>1</sup>

The FlatData language binding can be applied to any mutable type. This enables support for variable-size types containing bounded sequences, bounded strings, or optional members (unbounded sequences or strings are not supported with FlatData). It also allows using unions.

FlatData cannot be applied to extensible types.

Final types provide the best performance, while mutable types are the most flexible. Typically, the best compromise between flexibility and performance comes from a mutable type whose largest member is either a final type or a sequence of final elements. In the **CameraImage** example, the top-level type is mutable, which allows for type evolution, optional members, and variable-size members (such as the

---

<sup>1</sup> These restrictions on final types only apply to the FlatData language binding. Final types with the plain language binding can be variable-size.

source string member). On the other hand, its member **pixels**, which contains the bulk of the data, is defined as a sequence of the final type **Pixel**, which allows for an efficient manipulation.

#### 34.1.4.2.2 Programming with FlatData Language Binding

When a type is marked with the FlatData language binding, the in-memory representation for samples of this type is equal to the wire representation (according to XCDR version 2<sup>1</sup>). That is, the data sample is in its serialized format at all times. To facilitate accessing and setting the sample content, *RTI Code Generator* generates helper types that provide the operations to create and access these data samples. These helper types are Samples, Offsets, and Builders.

A FlatData **Sample** is a buffer holding the wire representation of the data. In the code generated for the previous IDL, a sample of the type **CameraImage** contains this buffer. This is the top-level object that can be written or read:

```
typedef rti::flat::Sample<CameraImageOffset> CameraImage;
```

(**Note:** These examples show code for the Modern C++ API. See [34.1.4.2.3 Languages Supported by FlatData Language Binding on page 515](#).)

To access this sample, applications use **Offset** types. An Offset represents the type of a member and its location in the buffer. An Offset can be described as an “iterator,” a light-weight object that points to the data, but doesn’t own it. Copying an Offset copies the “iterator,” not the data it points to.

```
class NDDUSERDllExport CameraImageConstOffset : public rti::flat::MutableOffset {
public:
    const rti::flat::StringOffset source() const;
    Format format() const;
    Resolution::ConstOffset resolution() const;
    rti::flat::SequenceOffset<Pixel::ConstOffset> pixels() const;
};

class NDDUSERDllExport CameraImageOffset : public rti::flat::MutableOffset {
public:
    typedef CameraImageConstOffset ConstOffset;

    // Const accessors
    const rti::flat::StringOffset source() const;
    Format format() const;
    Resolution::ConstOffset resolution() const;
    rti::flat::SequenceOffset<Pixel::ConstOffset> pixels() const;

    // Modifiers
    rti::flat::StringOffset source();
    bool format(Format value);
    Resolution::Offset resolution();
    rti::flat::SequenceOffset<Pixel::Offset> pixels();
};
```

<sup>1</sup> See *Data Representation*, in the [RTI Connext Core Libraries Extensible Types Guide](#) for more information on XCDR2.

There are two kinds of Offset types:

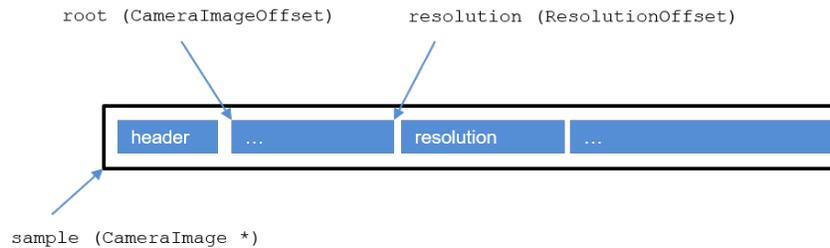

- Generated, named Offsets, to access a user-defined struct or union type (**CameraImageOffset**, **PixelOffset**). They provide accessors to directly get or set primitive members, and one getter for each non-primitive member to retrieve its corresponding Offset.

Each named offset has a corresponding read-only version (**CameraImageConstOffset**). This is analogous to a read-only iterator (e.g., `std::vector<T>::const_iterator` and `std::vector<T>::iterator`).

- Offsets to arrays, sequences, strings, and other IDL types. They provide access to their elements. Primitive elements can be accessed directly; non-primitive elements are accessed through Offsets for their types.

For details on all the Offset types and their interface, see the API Reference HTML documentation, under RTI Connex API Reference > Topic Module > FlatData Topic-Types.

The function **CameraImage::root()** provides the Offset to the top-level type (**CameraImageOffset**). If the sample is **const** (for example, in a **LoanedSamples** container), **root()** returns a read-only offset (**CameraImageConstOffset**).

To create variable-size (mutable) data-samples, applications use **Builders**. A Builder type provides the interface to create a mutable sample member by member. Once all the desired members for a sample have been added, the Builder is “finished,” returning the built sample, which can be published.

```
class NDDUSERDllExport CameraImageBuilder : public rti::flat::AggregationBuilder {
public:
    typedef CameraImageOffset Offset;

    Offset finish();
    CameraImage * finish_sample();

    rti::flat::StringBuilder build_source();
    bool add_format(Format value);
    Resolution::Offset add_resolution();
    rti::flat::FinalSequenceBuilder<Pixel::Offset> build_pixels();
};
```

Builders provide three kinds of functions:

- **add\_<member>** functions insert a member of a final type, returning an Offset to it.
- **build\_<member>** functions provide another Builder to create a member of a mutable type.
- **finish** and **finish\_sample** end the construction of a member or a sample, respectively.

Similarly to Offsets, Builders can correspond to user-defined struct and union types, or other IDL types such as sequences, arrays, and strings. For details on all the Builder types see the API Reference HTML documentation.

The following sections summarize how to use FlatData language binding:

- [Creating a FlatData sample below](#)
- [Writing a FlatData sample on page 511](#)
- [Reading a FlatData sample on page 511](#)
- [Working with unmanaged FlatData samples on page 512](#)
- [Multi-threading notes on page 513](#)
- [Notes on extensible types on page 514](#)

### Creating a FlatData sample

The following sections assume you have created a *DataWriter* for the type **Pixel** or **CameraImage**, following the usual process.

To write FlatData, first create a FlatData sample. The way to create a sample varies depending on whether the type is final or mutable. In both cases, this section shows how to create *DataWriter*-managed samples. See also [Working with unmanaged FlatData samples on page 512](#).

#### *Creating a FlatData sample for a final type*

In this section we will create a sample for the final type **Pixel**. To create a sample for the mutable type **CameraImage**, see *Creating a FlatData sample for a mutable type* after this.

Samples for final FlatData types are created directly with a single call to the *DataWriter* function **get\_loan**. The *DataWriter* manages this sample and will return it to a pool at some point after the sample is written.

```
Pixel *pixel_sample = writer.extensions().get_loan();
```

**pixel\_sample** contains the buffer that can be written. To set its values, first locate the position of the top-level type:

```
PixelOffset pixel = pixel_sample->root();
```

The **root()** function returns **PixelOffset**, which points to the position where the data begins. To set the values, use the following setters:

```
pixel.red(10);
pixel.green(20);
pixel.blue(30);
```

### *Creating a FlatData sample for a mutable type*

Samples for mutable types are created using Builders. To obtain a **CameraImageBuilder** to build a **CameraImage** sample, use the function **build\_data**:

```
CameraImageBuilder image_builder = rti::flat::build_data(writer);
```

This function loans the memory necessary to create a **CameraImage** sample from the *DataWriter* and provides a **CameraImageBuilder** to populate it.

Use the Builder functions to set the sample's members in any order. For a FlatData type that is also mutable, such as this one, you must call methods ("add" or "build") to set all the members you want to be sent. If you don't set a member's value, that member won't be sent by *Connex*. If a member is a key of the data-type, you must set its value; otherwise the *DataWriter's* write operation will fail. Effectively, all non-key members of a FlatData, mutable data type are treated as if they were `@optional`. (See *Optional Members, in the Type System Enhancements* chapter of the [RTI Connex Core Libraries Extensible Types Guide](#).)

These Builder functions work on a pre-allocated buffer; they do not allocate any additional memory.

First, we add the member **format**. As a primitive member, the function **add\_format** directly adds the member and sets its value:

```
image_builder.add_format(Format::RGB);
```

Next, we add the member **resolution**. Its type being final, the function **add\_resolution** adds the member and provides the Offset that allows setting its values:

```
ResolutionOffset resolution = image_builder.add_resolution();
resolution.height(100);
resolution.width(200);
```

To build the string member **source**, the function **build\_source** returns a **StringBuilder**. We use this builder (in this case it's as simple as calling **set\_string**), and then call **finish**. The function **finish** (not to be confused with **finish\_sample**) completes the construction of the member and renders **source\_builder** invalid.

```
auto source_builder = image_builder.build_source();
source_builder.set_string("CAM-1");
```

```
source_builder.finish();
```

Since this builder is so simple, it is possible to simplify the above code:

```
image_builder.build_source().set_string("CAM-1");
```

(The Builder destructor takes care of calling **finish**.)

To create the **pixels** member, we build a sequence of Pixels:

```
auto pixels_builder = image_builder.build_pixels();
```

There are two ways to populate this member.

*Method 1:* add and initialize each element:

```
for (int i = 0; i < 20000; i++) {
    PixelOffset pixel = pixels_builder.add_next();
    pixel.red(i % 256);
    pixel.green((i + 1) % 256);
    pixel.blue((i + 2) % 256);
}
pixels_builder.finish();
```

Builders for sequences with elements of a final type provide the function **add\_next** to add the elements. When the element type is mutable, the sequence (and array) Builder provides the function **build\_next**, which provides a Builder for each element. See more details in the API Reference HTML documentation.

*Method 2:* cast the elements in the sequence to the equivalent C++ plain type. This method only works for types that meet the conditions required by **rti::flat::plain\_cast**, as described in the API Reference HTML documentation. Basically, the in-memory representation must match the XCDR2 serialized representation. **Pixel** meets these conditions.

Method 2 is more efficient. First, we use the Builder function **add\_n** to add 20000 elements at once, leaving them uninitialized. Then, after finishing the Builder, we obtain the Offset to the member, cast it, and manipulate the data as a plain C++ type:

```
pixels_builder.add_n(20000);
auto pixels_offset = pixels_builder.finish();

auto plain_pixels = rti::flat::plain_cast(pixels_offset);
for (int i = 0; i < 20000; i++) {
    plain_pixels[i].red(i % 256);
    plain_pixels[i].green((i + 1) % 256);
    plain_pixels[i].blue((i + 2) % 256);
}
```

The function **rti::flat::plain\_cast** casts the position in memory that **pixels\_offset** points to into a C-style array of **PixelPlainHelper**, a type with the same IDL definition as **Pixel**, but with **@language\_binding(PLAIN)**. **plain\_cast** can receive an offset to a final struct, or an offset to an array or sequence of final structs or primitive types. See the API Reference HTML documentation for more information.

Finally, call **finish\_sample** to obtain the complete sample. After this, the Builder instance is invalid and cannot be further used.

```
CameraImage *image_sample = image_builder.finish_sample();
```

Once the sample has been created, it is still possible to modify its values, as long as these modifications don't change the size. For example, it is possible to change the value of an existing pixel, but it's not possible to add a new one:

```
auto pixels_offset = image_sample->root().pixels();
pixels_offset.get_element(100).blue(0);
```

The next section shows how to write the sample.

### Writing a FlatData sample

When you write a sample using a regular *DataWriter* (for a type with a plain language binding), the *DataWriter* copies the sample in its internal queue, so when **write()** ends, the application still owns the sample. A *DataWriter* for a FlatData type, however, doesn't copy the sample; it keeps a reference. You yield ownership of the data sample from the moment you call **write()**.

```
writer.write(*image_sample);
```

The *DataWriter* will decide when to return samples created with **get\_loan** or **build\_data** to a pool, where the sample will be reused.

To write a new sample, don't use **image\_sample** again, but obtain a new one with **get\_loan** or build a new one with **build\_data**.

If the sample cannot be written, to return it to the *DataWriter* pool call:

```
writer.extensions().discard_loan(*image_sample);
```

Or, if the sample has not been completely built yet, discard the Builder:

```
rti::flat::discard_builder(writer, image_builder);
```

### Reading a FlatData sample

The method for reading data for a FlatData type is the same regardless of whether the type is final or mutable.

Create a *DataReader* as you normally would; see [40.1 Creating DataReaders on page 620](#).

Read the data samples:

```
dds::sub::LoanedSamples<CameraImage> samples = camera_reader.take();
```

Let's work with the first sample (assuming **samples.length() > 0** and **samples[0].info().valid()**):

```
const CameraImage& image_sample = samples[0].data();
```

Using the **root** Offset and the Offset to the members, the following code prints the sample values. Note that in this example, **image\_sample** is **const**, so **camera\_image** is a **CameraImageConstOffset**, which only allows reading the buffer, not modifying it.

```
auto camera_image = image_sample->root();

std::cout << "Source: " << camera_image.source().get_string() << std::endl;
std::cout << "Timestamp: " << camera_image.timestamp() << std::endl;
std::cout << "Format: " << camera_image.format() << std::endl;

auto resolution = camera_image.resolution();
std::cout << "Resolution (height: " << resolution.height()
    << ", width: " << resolution.width() << ")\n";
```

Some members of **image\_sample** may not exist. For example, if the field **resolution** wasn't received, then **resolution.is\_null()** is true; if **timestamp** is not received, **camera\_image.timestamp()** returns 0.

To access the sequence of pixels, the same two methods that allowed building it (element by element or plain cast) are available:

*Method 1* (access each element offset):

```
for (auto pixel : camera_image.pixels()) {
    std::cout << "Pixel (" << pixel.red() << ", " << pixel.green()
        << ", " << pixel.blue() << ")\n";
}
```

*Method 2* (**plain\_cast**):

```
auto pixel_count = camera_image.pixels().element_count();
auto plain_pixels = rti::flat::plain_cast(camera_image.pixels());
for (int i = 0; i < pixel_count; i++) {
    const auto& pixel = plain_pixels[i];
    std::cout << "Pixel (" << pixel.red() << ", " << pixel.green()
        << ", " << pixel.blue() << ")\n";
}
```

Method 2 is more efficient, provided that the type meets the requirements of **plain\_cast**. Also, the endianness of the publishing application must be the same as the local endianness.

Note that you can directly print the sample:

```
std::cout << *image_sample << std::endl;
```

### Working with unmanaged FlatData samples

The previous sections describe how to create and write *DataWriter*-managed samples (via **get\_loan** or **build\_data**). While this is the recommended and easiest way, sometimes applications may need to use unmanaged samples. For example, they may need to reuse the same sample after it is written or to obtain the memory from some other source.

Note that a given *DataWriter* cannot write both unmanaged and managed samples. The functions **get\_loan** or **build\_data** will fail if an unmanaged sample has been written. Conversely, the *DataWriter* will fail to write an unmanaged sample if **get\_loan** or **build\_data** have been called.

To create a **CameraImage** using memory from an arbitrary buffer, **my\_buffer**, with a capacity of **my\_buffer\_size** bytes, use the following constructor:

```
unsigned char *my_buffer = ...;
unsigned int my_buffer_size = ...;
CameraImageBuilder image_builder(my_buffer, my_buffer_size);
// use image_builder...
CameraImage *image_sample = image_builder.finish_sample();
```

**image\_builder** will fail if it runs out of space. The maximum size of a **CameraImage** can be obtained from its dynamic type:

```
unsigned int max_size =
rti::topic::dynamic_type<CameraImage>::get().cdr_serialized_sample_max_size();
```

After writing **image\_sample**, the *DataWriter* takes ownership of it. In order to reuse the sample, the application needs to monitor the **on\_sample\_removed** callback in the *DataWriter* listener, and correlate the cookie it receives with the sample. The following is a simple *DataWriterListener* implementation that does that:

```
class FlatDataWriterListener
: public dds::pub::NoOpDataWriterListener<CameraImage> {
public:
    void on_sample_removed(
        dds::pub::DataWriter<CameraImage>& writer,
        const rti::core::Cookie& cookie) override
    {
        // The cookie identifies the sample being removed
        last_removed_sample = cookie.to_pointer<CameraImage>();
    }

    CameraImage *last_removed_sample = NULL;
};
```

The application will need to wait until **last\_removed\_sample** is equal to **image\_sample**. This indicates that the *DataWriter* no longer needs to hold ownership of **image\_sample**.

Another way to create an unmanaged sample is **CameraImage::create\_data()** or **Pixel::create\_data()** (the result of **CameraImage::create\_data()** must be passed to the **CameraImageBuilder** constructor mentioned before). Samples can be copied with the **clone()** function. These samples need to be released with the respective **delete\_data()** functions. See the API Reference HTML documentation for more information.

### Multi-threading notes

- It's not safe to use the same Offset object in parallel, even for reading. For efficiency, each offset object contains an internal state that may change when accessing a member.

```
void my_thread1(CameraImageOffset& camera_image)
{
    auto format = camera_image.format();
}

void my_thread2(CameraImageOffset& camera_image)
{
    auto resolution = camera_image.resolution();
}

// Unsafe:
auto camera_image = camera_image_sample.root();
std::async(my_thread1, camera_image);
std::async(my_thread2, camera_image);
```

- It is safe to use different Offset objects to read the same member in a sample.

```
// Safe
auto camera_image1 = camera_image_sample.root();
auto camera_image2 = camera_image_sample.root();
std::async(my_thread1, camera_image1);
std::async(my_thread2, camera_image2);
```

- It is not safe to build a sample using a Builder in parallel.

### Notes on extensible types

There are a few differences in how a plain and a FlatData *DataReader* behave when they receive samples of types that are different but compatible.

Before a *DataReader* and *DataWriter* can communicate, their types are inspected to determine if they are compatible. The same is true when using FlatData; however, even after two types have been deemed compatible, there may be specific data samples that are not.

*DataReaders* for plain types verify sample compatibility during data deserialization, but *DataReaders* for FlatData types don't deserialize the data, passing FlatData samples directly to the application. For that reason, there may be situations where a plain *DataReader* would lose or reject a data-sample, while a *DataReader* for a FlatData type with the same definition will pass the same sample to the application. Therefore, if you are using FlatData you may need to explicitly check if all the received samples are consistent with your application logic. For more information on the rules that determine the assignability of a sample, see the [RTI Connex Core Libraries Extensible Types Guide](#) (see the section "Verifying Sample Consistency: Sample Assignability") or the [OMG 'Extensible and Dynamic Topic Types for DDS' specification, version 1.3](#).

For example, a FlatData *DataReader* won't drop a sample when a sequence (or a string) member exceeds the bounds in the reader's type definition, and the application will be able to read this sequence

(or string). This can only happen if `ignore_sequence_bounds` (or `ignore_string_bounds`) in `TypeConsistencyEnforcement` is set to true; otherwise the `DataWriter`'s type won't match the `DataReader`'s. The `@min` and `@max` annotations are another example. FlatData `DataReaders` will not enforce the `@min/@max` range set for a member, and applications will be able to access such samples.

Another difference in behavior involves the reception of samples that don't include some data members. When a regular `DataReader` for a mutable (plain) type receives a data sample that doesn't include one of its non-optional members, it automatically assigns a default value during the data deserialization. A FlatData `DataReader` for a mutable (FlatData) type will not do that. Instead, if the application tries to access that member, the corresponding member getter will return a null `Offset`. Only if the member is primitive will it return a default value. This means that, for a FlatData `DataReader` in this case, all non-primitive members will be treated as if they were optional.

#### 34.1.4.2.3 Languages Supported by FlatData Language Binding

The FlatData language binding is supported in the Modern and Traditional C++ APIs:

- `rtiddsgen -language C++11` generates code for the Modern C++ API.
- `rtiddsgen -language C++98` generates code for the Traditional C++ API.

The FlatData language binding is basically the same in both APIs, as described in the previous sections, with a few differences:

- Modern C++ may throw exceptions in `Sample`, `Offset`, and `Builder` operations, such as `dds::core::PreconditionNotMetError`; Traditional C++ doesn't throw exceptions and in these cases it would return invalid objects. See the API Reference HTML documentation for each language for details.
- Modern C++ maps integer types to `int32_t`, `uint16_t`, etc; Traditional C++ uses `DDS_Long`, `DDS_UnsignedShort`, etc. This is consistent with these languages' respective plain language bindings.
- Modern C++ provides an overloaded `operator<<` to print a sample; Traditional C++ uses `FooTypeSupport::print_data`. Both provide a function to transform to a string with format options. This behavior is also consistent with the plain binding.

#### 34.1.4.2.4 Interactions with RTI Security Plugins and Compression

When the FlatData language binding is used in combination with either payload encryption or compression (see [47.3 DATA REPRESENTATION QosPolicy on page 780](#)), there is no reduction in the number of copies used to send or receive the samples. There are unavoidable copies that must be made during the encryption/decryption and/or compression/decompression processes, resulting in the same number of copies that would be made if you were using regular data in combination with these features. This is a known issue that will be addressed in future releases (see "Known Issues" in the [RTI Connex Core Libraries Release Notes](#)).

Therefore, using the FlatData language binding in combination with payload encryption and/or compression is not generally useful. However, when using Zero Copy transfer over shared memory, you will also need to use FlatData for variable-sized data types. (See [34.1.3 Choosing between FlatData Language Binding and Zero Copy Transfer over Shared Memory on page 503](#).) In this case, you may want to configure the *DataWriter* to use encryption/compression when sending to *DataReaders* running on different hosts, even though you are not saving copies. This configuration allows using Zero Copy for *DataReaders* running on the same host as the *DataWriter*, while encrypting/compressing data that is sent to *DataReaders* on different hosts.

#### 34.1.4.2.5 Notes on Batching

A FlatData *DataWriter* (a *DataWriter* that sends FlatData samples) cannot batch samples. That is, *Connex* will not let you set up a FlatData *DataWriter* to use batching. Both FlatData and regular *DataReaders*, however, can receive batched samples from a regular *DataWriter* as well as all samples from a FlatData *DataWriter*.

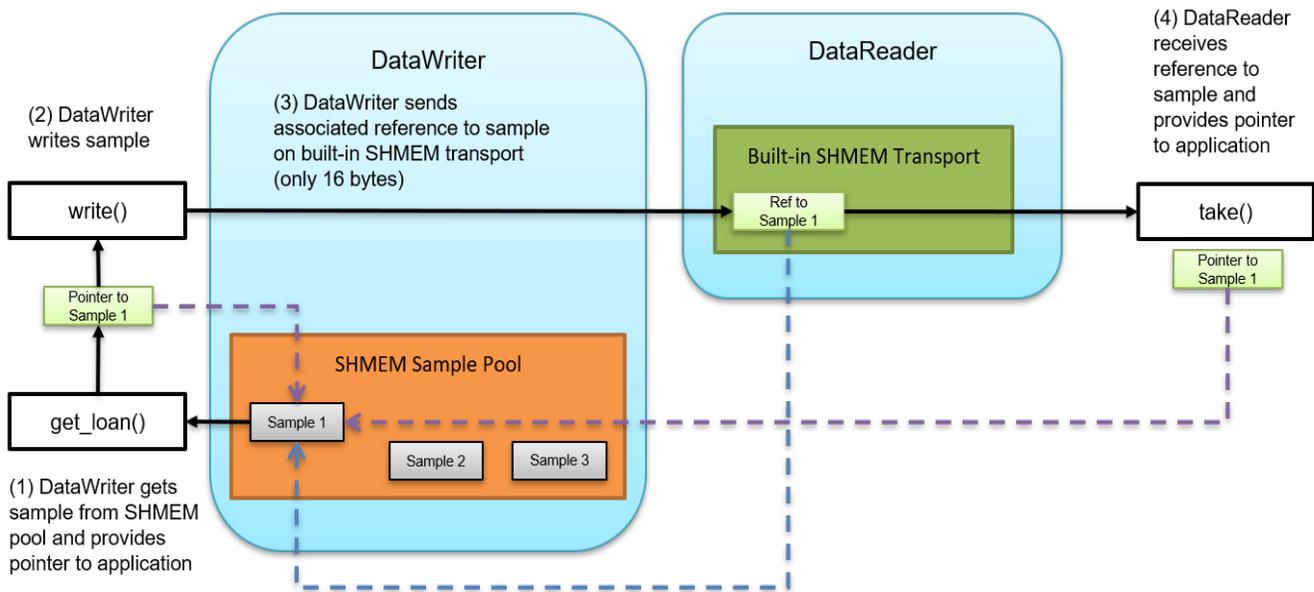

### 34.1.5 Zero Copy Transfer Over Shared Memory

For communication within the same node using the built-in shared memory transport, by default *Connex* copies a sample four times (see [Figure 34.3: Number of Copies Out-of-the-Box on page 501](#)). FlatData language binding reduces the number of copies to two (see [Figure 34.4: Number of Copies Using FlatData Language Binding on page 502](#)): the copy of the sample into the shared memory segment in the publishing application and the copy to reassemble the sample in the subscribing application. Two copies, however, may still be too many depending on the sample size and system requirements.

Zero Copy transfer over shared memory, provided as a separate library called *nddsmetp*, allows reducing the number of copies to zero for communications within the same host. The *nddsmetp* library can be linked with *Connex* C or C++ libraries. This feature accomplishes zero copies by using the shared memory (SHMEM) built-in transport to send 16-byte references to samples within a SHMEM segment owned by the *DataWriter*, instead of using the SHMEM built-in transport to send the serialized sample content by making a copy. See [Figure 34.5: Zero Copy Transfer Over Shared Memory on the next page](#).

With Zero Copy transfer over shared memory, there is no need for the *DataWriter* to serialize a sample, and there is no need for the *DataReader* to deserialize an incoming sample since the sample is accessed directly on the SHMEM segment created by the *DataWriter*.

Figure 34.5: Zero Copy Transfer Over Shared Memory

This feature offers the following benefits:

- Number of copies is reduced from four to zero (see SHMEM in [Figure 34.3: Number of Copies Out-of-the-Box on page 501](#)). Instead of transferring the entire sample by making multiple copies, only the location in shared memory is distributed to *DataReaders* (see [Figure 34.5: Zero Copy Transfer Over Shared Memory](#) above).
- Because of this reduced data copying, memory consumption and CPU load are also reduced.
- Latency is independent of the size of the sample.
- Fragmentation is not required when using Zero Copy transfer over shared memory because the *DataWriter* exchanges SHMEM references (only 16-bytes) with *DataReaders* and not the full sample.
- Data can still be sent off-board, simplifying application deployment and configuration. When the data is sent off-board, the middleware is still making the same copies described in [Figure 34.3: Number of Copies Out-of-the-Box on page 501](#). To reduce the number of copies for sending off-board, use FlatData language binding in conjunction with Zero Copy transfer over shared memory.

**Note:** A Zero Copy *DataWriter* is defined as any *DataWriter* with the ability to send a sample reference. You can have a *DataWriter* that does both: sends sample references to Zero Copy *DataReaders*, and sends serialized samples to non-Zero Copy *DataReaders*. In this case, the *DataWriter* is still considered a Zero Copy *DataWriter* in this documentation.

### 34.1.5.1 Using Zero Copy Transfer Over Shared Memory

To use Zero Copy transfer over shared memory, perform the following basic steps:

- Identify types that require Zero Copy transfer over shared memory and annotate them with `@transfer_mode(SHMEM_REF)` in the IDL files. (See: [17.3.9.8 The @transfer\\_mode annotation on page 204.](#))

**Note:** Zero Copy transfer over shared memory requires the FlatData language binding when the type is variable-size.

- Use the *DataWriter*'s `get_loan()` API to get a loaned sample for writing with Zero Copy. (You would use this API to create the sample rather than creating the sample using the `TypeSupport`. See the example in the following sections and the API Reference HTML documentation for more information on `get_loan()`.)
- Link the publisher and subscriber application with the additional Zero Copy library, *nddsmetp*. (*RTI Code Generator (rtiddsgen)* generates examples that link *nddsmetp* for you automatically. If you are using a custom build system, make sure you link with *nddsmetp*.)

*RTI Code Generator* generates additional `TypePlugin` code when a type is annotated with `@transfer_mode(SHMEM_REF)` in the IDL files. This code allows a *DataWriter* and a *DataReader* to communicate using a reference to the sample in shared memory (see [Figure 34.5: Zero Copy Transfer Over Shared Memory on the previous page](#)). In addition to sending a sample reference, the *DataWriter* can also send the serialized sample to a *DataReader* that doesn't support Zero Copy transfer over shared memory.

The following sections contain more information about using Zero Copy transfer over shared memory:

- [34.1.5.1.1 Sending data with Zero Copy transfer over shared memory below](#)
- [34.1.5.1.2 Receiving data with Zero Copy transfer over shared memory on page 520](#)
- [34.1.5.1.3 Checking data consistency with Zero Copy transfer over shared memory on page 521](#)
- [34.1.5.1.4 Languages Supported by Zero Copy Transfer Over Shared Memory on page 522](#)
- [34.1.5.1.5 Interactions with RTI Security Plugins and Compression on page 522](#)
- [34.1.5.1.6 Notes on Batching on page 523](#)

For examples of FlatData language binding and Zero Copy transfer over shared memory, including example code, see <https://community.rti.com/kb/flatdata-and-zerocopy-examples>.

#### 34.1.5.1.1 Sending data with Zero Copy transfer over shared memory

The following example shows how to use Zero Copy transfer mode for a surveillance application in which high-definition (HD) video signal is published and subscribed to. The application publishes a

Topic of the type **CameraImage**. This is the IDL:

```
enum Format {
    RGB,
    HSV,
    YUV
};

struct Resolution {
    int32 height;
    int32 width;
};

const long IMAGE_SIZE = 8294400 * 3;

@transfer_mode(SHMEM_REF)
struct CameraImage {
    int64 timestamp;
    Format format;
    Resolution resolution;
    octet data[IMAGE_SIZE];
};
```

The **CameraImage** type is annotated with `@transfer_mode(SHMEM_REF)` to allow Zero Copy communication. Note that it is sufficient to annotate only top-level types with this annotation.

Any final or appendable type annotated with `@transfer_mode(SHMEM_REF)` should be a fixed-size type. This means the type can include primitive members, arrays of fixed-size types, and structs containing only members of fixed-size types. To use a variable-sized type, the type should be annotated with `@language_binding(FLAT_DATA)` and `@mutable` in combination with `@transfer_mode(SHMEM_REF)`.

With Zero Copy transfer mode, an application writes samples coming from a shared memory sample pool created by a Zero Copy *DataWriter*. Therefore, create a *DataWriter* before creating a sample. The steps for creating a Zero Copy *DataWriter* are the same as for a regular *DataWriter*.

```
const int MY_DOMAIN_ID = 0;
dds::domain::DomainParticipant participant(MY_DOMAIN_ID);
dds::topic::Topic<CameraImage> camera_topic(participant, "Camera");
dds::pub::DataWriter<CameraImage> camera_writer(
    rti::pub::implicit_publisher(participant),
    camera_topic);
```

To get a sample from shared memory, use the *DataWriter*'s `get_loan()` API:

```
CameraImage *camera_image = camera_writer->get_loan();
```

The sample returned by `get_loan()` is uninitialized by default (the members are not set to default values). If you would like to allow the *DataWriter* to return an initialized sample from `get_loan()`, set **ini-**

Set `enable_writer_loaned_sample` to true in the [47.6 DATA\\_WRITER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\)](#) on page 800.

Populate the fields of the sample as you would a regular sample:

```
camera_image->timestamp(12345678);
camera_image->format(Format::HSV);
camera_image->resolution().height(1024);
camera_image->resolution().width(2048);
// populate the image data
```

The example above, showing the population of the fields, assumes regular PLAIN language binding. Zero Copy transfer over shared memory also works with types using FLAT\_DATA language binding. In this case, you must use the FlatData API described in [34.1.4 FlatData Language Binding](#) on page 503 to populate the sample.

The number of samples in the shared memory sample pool created by the *DataWriter* can be configured using the **writer\_loaned\_sample\_allocation** settings in the [47.6 DATA\\_WRITER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\)](#) on page 800.

Initially all the samples are in a free state. When you call the *DataWriter*'s `get_loan()`, the *DataWriter* provides a sample from this pool, and its state changes to allocated. The samples are provided using an LRU (Least Recently Used) policy.

Write the sample with the regular write operation:

```
camera_writer.write(*camera_image);
```

When a sample is written, its state transitions from allocated to enqueued, and the *DataWriter* takes responsibility for returning the sample back to the shared memory pool. The sample remains in the enqueued state until it is removed from the *DataWriter* queue. When this happens, the sample is put back into the shared memory sample pool, and its state transitions from enqueued to removed. At this time, a new call to the *DataWriter*'s `get_loan()` may return the same sample.

You should not try to reuse a sample that has been written with a *DataWriter* to publish a new value. Instead, get a new sample using the *DataWriter*'s `get_loan()` and populate its content with the new value.

A sample that has not been written can be returned to the shared memory pool by using the *DataWriter*'s `discard_loan()`:

```
camera_writer->discard_loan(camera_image)
```

The shared memory sample pool is destroyed when the *DataWriter* is deleted.

See the API Reference HTML documentation for more information on `get_loan()`.

#### 34.1.5.1.2 Receiving data with Zero Copy transfer over shared memory

Create a *DataReader* as you normally would; see [40.1 Creating DataReaders](#) on page 620.

Read the data samples:

```
dds::sub::LoanedSamples<CameraImage> samples = camera_reader.take();
```

Let's work with the first sample (assuming `samples.length() > 0` and `samples[0].info().valid()`):

```
const CameraImage& camera_image_sample = samples[0].data();
// Process the sample
process_data(camera_image_sample);
if (!camera_reader->is_data_consistent(camera_image_sample)) {
    // Sample was overwritten, ignore this sample
    rollback(camera_image_sample);
}
```

For more information on the *DataReader's* `is_data_consistent()` API, see [34.1.5.1.3 Checking data consistency with Zero Copy transfer over shared memory below](#).

### 34.1.5.1.3 Checking data consistency with Zero Copy transfer over shared memory

Zero Copy transfer over shared memory makes no copies. This means the sample being processed in the subscribing application actually resides in the *DataWriter's* send queue. The *DataWriter* in the publishing application can decide to reuse this memory to send a different sample before or while the original sample is being processed by a *DataReader*, which can lead to data consistency problems. There are several ways to prevent and detect these inconsistencies.

A reliable *DataWriter* will not attempt to reuse sample memory if the sample has not been acknowledged. With reliable communication and application-level acknowledgments (see [31.12 Application Acknowledgment on page 418](#)), the subscribing application can prevent the writer from reusing the sample by delaying the acknowledgment until after the sample has been processed.

**Note:** Application Acknowledgment is not currently available with *RTI Connext Micro*.

Applications can also use other, custom, application-level mechanisms to guarantee data consistency between the publisher and the subscriber.

Without an application-level synchronization mechanism, when the application's *DataWriter* and *DataReader* are not synchronized, the subscribing application can use the *DataReader's* `is_data_consistent()` API to detect data inconsistencies, as long as the type is not annotated with `@language_binding(FLAT_DATA)`. If the type is `FlatData`, reading a data sample while the *DataWriter* is reusing it is undefined behavior.

If the type is not `FlatData`, for `is_data_consistent()` to work, configure the *DataWriter's* [47.25 TRANSFER\\_MODE QoS Policy on page 855](#) setting `writer_qos.transfer_mode.shmem_ref_settings.enable_data_consistency_check` to true (the default). A *DataWriter* with this setting sends a special sequence number associated with each sample as an inline QoS (metadata), which can be used to check the sample's validity at the *DataReader* with the *DataReader's* `is_data_consistent()` API. Simply, the API checks if the shared memory space has been reused for that sample. If it has, the data is inconsistent.

If data consistency checks are disabled, `is_data_consistent()` will return a `PRECONDITION_NOT_MET` error.

The `is_data_consistent()` API helps detect a data inconsistency, not prevent it. Therefore, the recommended way of using the API is to follow this general scheme:

```
process(data);
if (!reader->is_data_consistent(data, sample_info))
    discard(processed_data);
```

When `is_data_consistent()` returns true *after* the sample has been processed, subscribers can be sure processed data was not inconsistent and can be trusted (e.g., by committing it to a database). When `is_data_consistent()` returns false, processed data should be discarded. If `is_data_consistent()` is only called *before* processing data, it could return true at that point but the sample could be modified while being processed, leading to a race condition. Therefore, if you want to call `is_data_consistent()` *before* processing the data (for instance, because the processing is expensive), that is fine, but be sure to also call it *after* processing the data.

If the publisher sends data in best-effort mode and the expected send frequency is known in advance, the *DataWriter's* resource limits can be configured with an appropriate `writer_loaned_sample_allocation` max count (see the API Reference HTML documentation) to minimize the chances of sample reuse and of `is_data_consistent()` returning false.

#### 34.1.5.1.4 Languages Supported by Zero Copy Transfer Over Shared Memory

Zero Copy transfer over shared memory is supported in the C, Modern C++, and Traditional C++ APIs.

#### 34.1.5.1.5 Interactions with RTI Security Plugins and Compression

When you use security in combination with Zero Copy transfer over shared memory, the samples in the shared memory segment are not serialized and are therefore not protected, regardless of the selected protection kind. With Zero Copy, *Security Plugins* only protects the 16-byte references sent to *DataReaders*. You can use any protection kind to protect the reference (see "Securing DDS Messages on the Wire" and "Understanding ProtectionKinds" in the *RTI Security Plugins User's Manual*).

If a *DataWriter* is using Zero Copy transfer over shared memory, the samples sent to *DataReaders* over non-shared memory transports will be serialized and protected according to the configured protection kinds (see "Related Governance Rules" in the *RTI Security Plugins User's Manual*).

Likewise, with compression (see [47.3 DATA\\_REPRESENTATION QosPolicy on page 780](#)), the samples in the shared memory segment are not serialized and are therefore not compressed, regardless of the compression setting. However, the shared memory reference (see [34.1.5 Zero Copy Transfer Over Shared Memory on page 516](#)) will be compressed if the `writer_compression_threshold` is set to a value less than or equal to 16 bytes. To avoid this compression when using Zero Copy, it is recommended to set the `writer_compression_threshold` to a value greater than 16.

If a *DataWriter* is using Zero Copy transfer over shared memory, the samples sent to *DataReaders* over non-shared memory transports will be serialized and compressed according to the compression settings.

#### 34.1.5.1.6 Notes on Batching

A Zero Copy *DataWriter* (a *DataWriter* that sends sample references) cannot batch samples. That is, *Connex* will not let you set up a Zero Copy *DataWriter* to use batching. A Zero Copy *DataReader*, however, can receive batched samples from a regular *DataWriter* as well as all samples from a Zero Copy *DataWriter*.

### 34.1.5.2 Other Considerations

#### 34.1.5.2.1 Type Matching for Zero Copy Transfer Over Shared Memory

The default value for `TypeConsistencyEnforcementQosPolicy` **kind** is `AUTO_TYPE_COERCION`.

For a regular *DataReader*, `AUTO_TYPE_COERCION` is translated to `ALLOW_TYPE_COERCION`. A Zero Copy *DataReader*, however, should use a topic type that is identical to its matched Zero Copy *DataWriter*'s topic type, because it accesses the sample directly in the *DataWriter* queue. Therefore, `AUTO_TYPE_COERCION` for a Zero Copy *DataReader* is translated to `DISALLOW_TYPE_COERCION`. The creation of a Zero Copy *DataReader* with `ALLOW_TYPE_COERCION` will return an error.

See [48.6 TYPE\\_CONSISTENCY\\_ENFORCEMENT QosPolicy on page 894](#).

#### 34.1.5.2.2 Resource Limits Related to Zero Copy Transfer Over Shared Memory

There are resource limits on the *DataWriter*, *DataReader*, and *DomainParticipant* that configure different aspects of Zero Copy transfer over shared memory.

##### DataWriter Resource Limits

The **writer\_loaned\_sample\_allocation** setting configures the initial and maximum number of loaned samples managed by the *DataWriter*. It also configures the growth policy.

By default this setting is derived from the `DDS_ResourceLimitsQosPolicy`: the initial and maximum counts are equal to **initial\_samples** + 1 and **max\_samples** + 1. The **incremental\_count** defaults to **initial\_count** if the **initial\_count** is not the same as **max\_count**. If these are the same, then **incremental\_count** defaults to 0.

If you want to extend the time to reuse a sample, use a large sample pool by increasing the **initial\_count** of the **writer\_loaned\_sample\_allocation**.

See [47.6 DATA\\_WRITER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 800](#).

##### DataReader Resource Limits

The **shmem\_ref\_transfer\_mode\_attached\_segment\_allocation** setting configures the initial and maximum shared memory segments to which a *DataReader* can attach.

By default this setting is derived from other fields in the `DDS_DataReaderResourceLimitsQosPolicy`: the initial and maximum counts of shared memory segments are equal to `initial_remote_writers` and `max_remote_writers`. The `incremental_count` defaults to -1 (doubling of resources) if the `initial_count` is not the same as `max_count`. If these are the same, then `incremental_count` defaults to 0.

The `max_count` controls the maximum number of shared memory segments that a *DataReader* can attach at a time. Once this limit is hit, if there is a need to attach to a new segment, the *DataReader* will try to detach from a segment that doesn't contain any loaned samples and attach to the new segment.

If there are samples loaned in all the attached segments, then the new segment will not be attached and this will result in losing the sample.

See [48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 876](#).

### DomainParticipant Resource Limits

The `shmem_ref_transfer_mode_max_segments` setting sets the maximum number of shared memory segments that can be created by all *DataWriters* belonging to the participant. The default value of this setting is 500. The maximum value of this setting will be limited by the operating system setting that controls the system wide maximum number of shared memory segments.

See [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 714](#).

## 34.2 Reducing Bandwidth Usage

Another important consideration when sending large samples (besides [34.1 Reducing Latency on page 498](#)) is bandwidth usage. *Connex* allows you to compress samples using different builtin algorithms described in [47.3 DATA\\_REPRESENTATION QosPolicy on page 780](#).

## 34.3 Large Data Fragmentation

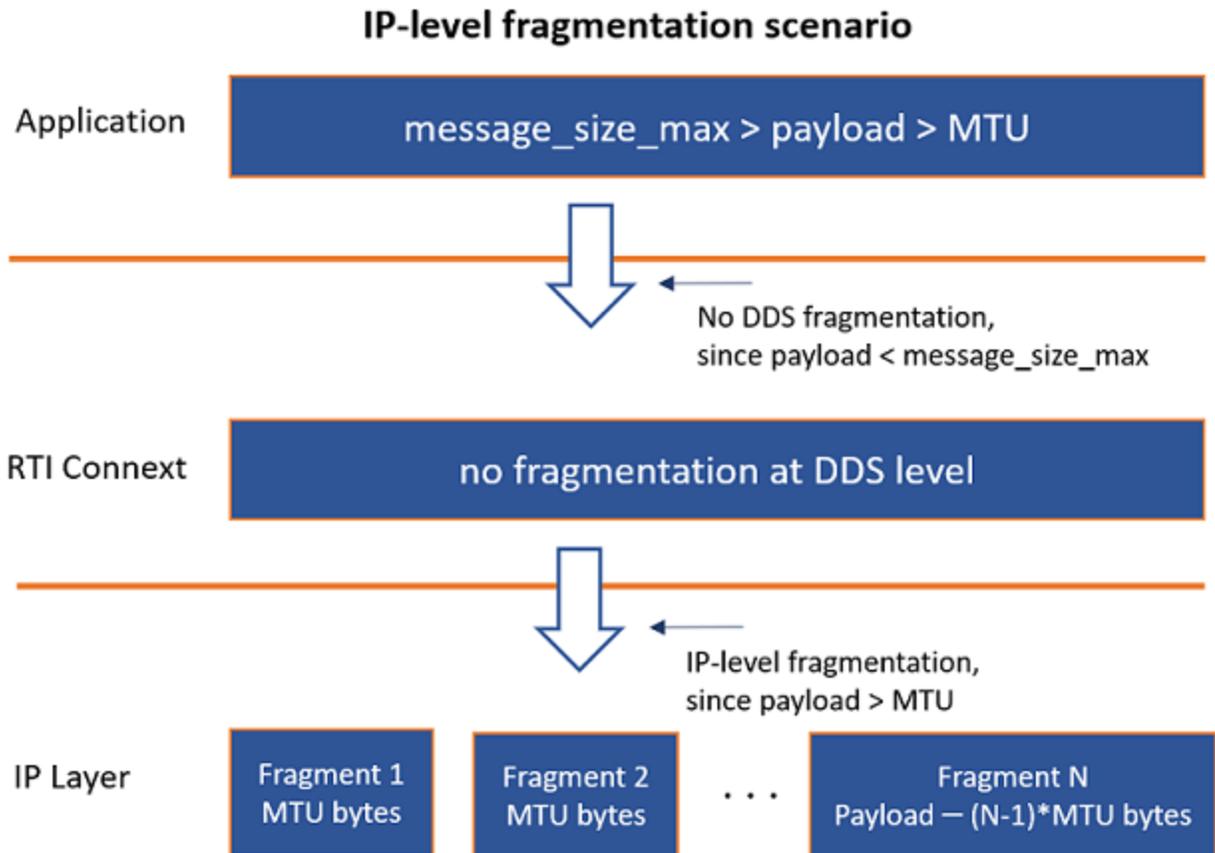

There are two types of fragmentation: IP-level fragmentation and DDS-level fragmentation.

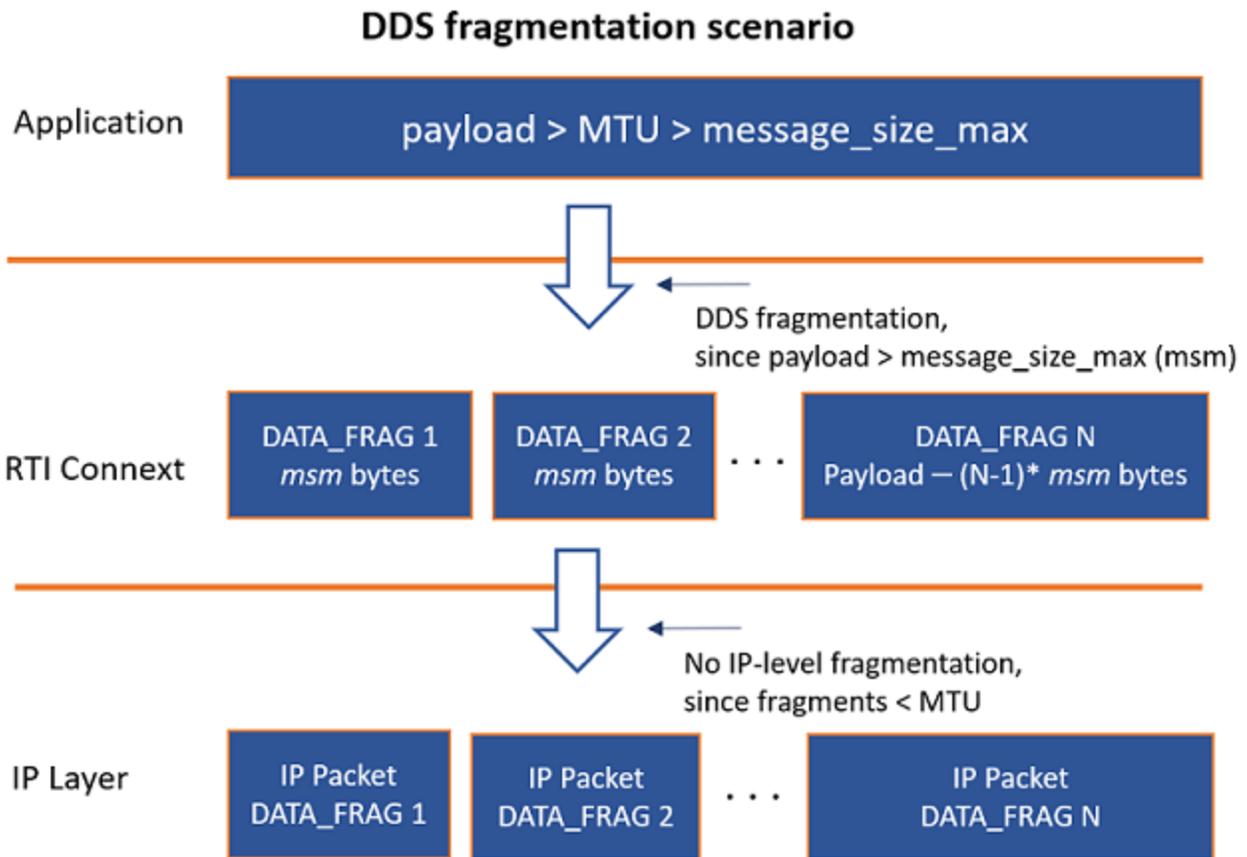

IP-level fragmentation occurs when the payload provided from the transport layer (typically UDP or TCP) exceeds the maximum payload size that fits in a link frame (also known as the link maximum transmission unit, or link MTU). If the network is an Ethernet network, then the link MTU is the maximum size of an Ethernet frame. When the receiver NIC gets IP fragments, it stores them in a buffer until all the fragments are received and can be reassembled to form UDP datagrams or TCP segments. When all the fragments are received, the reassembly is performed and the message is provided to the application layer.

If you try to send a DDS sample whose size is bigger than the MTU and you have not set up DDS-level fragmentation, you will see IP-level fragmentation. IP-level fragmentation is known to be fragile and can lead to communication issues if your system is not configured properly. For example, when your application relies on the transport to fragment the data and one fragment is lost, then all of the

fragments need to be resent to repair the missing fragment—whereas if you use Reliable reliability (see [47.21 RELIABILITY QoSPolicy on page 845](#)), *Connex* can repair a single lost DDS fragment.

The following diagrams show the differences between IP-level fragmentation and DDS-level fragmentation. RTPS, UDP, and IP headers are not shown in the diagrams, for simplification purposes.

The main advantages of letting DDS do the fragmentation instead of letting the IP layer do it are as follows:

- IP packets containing `DATA_FRAG` messages (DDS fragments) are automatically provided from the NIC's buffer to the DDS application without having to wait for reassembly. This helps prevent overflow of the NIC's buffer due to many fragments.
- The middleware handles fragmentation and reassembly of fragments. As a result, when using the Reliable [47.21 RELIABILITY QosPolicy on page 845](#), if an IP packet containing a `DATA_FRAG` is not received, *Connex*'s reliable protocol will try to repair the missing `DATA_FRAG` instead of the entire DDS packet. This may help reduce network traffic in scenarios with reliable communication. It is highly recommended to use Reliable reliability in combination with fragmentation; otherwise a single lost fragment will cause the entire sample to be dropped, leading to excessive sample losses.

The main cost of using DDS-level fragmentation is that having *Connex* handle fragmentation may introduce a performance degradation compared to an ideal case where there are no IP-level fragmentation issues. However, if there are IP-level fragmentation issues in your system, DDS-level fragmentation is a good way to avoid them. There are many different types of IP-level fragmentation

issues, including, but not limited to, mismatched MTU sizes across your network path, OS-specific implementation limitations, and hardware that simply does not allow IP fragment forwarding.

**Note:** Batching does not currently support DDS-level fragmentation (also known as RTPS fragmentation). If you use batching, you will currently not be able to take advantage of *Connex*-level fragmentation. This means that your batch size has to be set to a value smaller than the minimum transport MTU across all the installed *Connex* transports. (You configure the MTU by setting `message_size_max` in the transport properties. See the next section, [34.3.1 Avoiding IP-Level Fragmentation below](#).)

You can configure the batch size for user data using either the `max_data_bytes` or `max_samples` QoS values in the [47.2 BATCH QosPolicy \(DDS Extension\) on page 773](#). In either case, you need to take into account that there is some overhead of metadata per sample in a batch that can be as big as 120 bytes per sample depending on what DDS features you use. A common value when using keyed topics is 40 bytes of metadata per sample and 12 for unkeyed topics.

### 34.3.1 Avoiding IP-Level Fragmentation

IP-level fragmentation can be avoided if the DDS payload (plus UDP headers) size is shorter than the Ethernet MTU. The most common Ethernet MTU size is 1500 bytes (although this size should not be assumed, since there are many cases in which it is set to a value other than 1500). The maximum UDP payload that fits on a 1500-byte Ethernet MTU is 1472 bytes. This is because, out of the 1500 bytes in the Ethernet MTU, 20 bytes are used by the IP header and 8 more by the UDP header. You can easily know the size of your NIC's MTU in Linux systems with the following command:

```
> ifconfig
```

In Windows systems, the MTU for your NICs is shown by this command:

```
> netsh interface ipv4 show subinterface
```

*Connex* provides a property, `message_size_max`, to set the maximum size of an RTPS packet. See [51.6 Setting Builtin Transport Properties with the PropertyQosPolicy on page 960](#) for information on how to set transport properties. Samples that have a serialized size larger than the `message_size_max` will be fragmented by DDS. Therefore, setting this property to a value less than or equal to the maximum UDP payload that fits in the Ethernet MTU (that is, smaller than 1472 bytes in the common case) makes DDS fragment the data packets so that each RTPS message can fit in a single Ethernet frame. These DDS fragments are referred to as `DATA_FRAG` messages.

**Note:** MTU sizes are not necessarily uniform across an entire network path from source to destination. In these cases, it is important to understand the MTU sizes throughout your network and to set the DDS `message_size_max` to a value smaller than the smallest payload that fits in the MTU size in your network. TCP avoids IP-level fragmentation and automatically detects MTU sizes across a network path through a process called Path MTU Discovery. If you're using UDP, then it is currently up to you to know and understand the MTU sizes in your network if you want to avoid IP-level fragmentation.

A more granular configuration of DDS-level fragment management can be controlled with properties such as **max\_fragments\_per\_sample** (see [48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QoSPolicy \(DDS Extension\) on page 876](#)).

While *Connex* supports unbounded types and data fragmentation, there are practical serialization limits for any given sample. These limits are described in [17.10 Data Sample Serialization Limits on page 245](#).

**Note:** Features that are targeted at applications that handle large data, like the *FlatData language binding* and *Zero Copy over shared memory* features (see [Chapter 34 Sending Large Data on page 497](#)), have no effect on how data is fragmented by DDS.

*Connex* provides a builtin-in XML snippet that can be used to configure the middleware to avoid IP fragmentation. The snippet name is `Transport.UDP.AvoidIPFragmentation`, and you can use it as follows:

```
<qos_profile name="AvoidIPFragmentation">
  <base_name>
    <element>Transport.UDP.AvoidIPFragmentation</element>
  </base_name>
</qos_profile>
```

The snippet does two things:

- Sets the builtin-in UDP Transport MTU (`<message_size_max>`) to be 1400 bytes.
- Enables DDS fragmentation for reliable Topics (user and builtin Topics) by configuring the [47.20 PUBLISH\\_MODE QoSPolicy \(DDS Extension\) on page 843](#).

The following XML shows what the `Transport.UDP.AvoidIPFragmentation` snippet sets, for reference:

```
<qos_profile name="Transport.UDP.AvoidIPFragmentation">
  <domain_participant_qos>
    <discovery_config>
      <publication_writer_publish_mode>
        <kind>ASYNCHRONOUS_PUBLISH_MODE_QOS</kind>
      </publication_writer_publish_mode>
      <subscription_writer_publish_mode>
        <kind>ASYNCHRONOUS_PUBLISH_MODE_QOS</kind>
      </subscription_writer_publish_mode>
      <secure_volatile_writer_publish_mode>
        <kind>ASYNCHRONOUS_PUBLISH_MODE_QOS</kind>
      </secure_volatile_writer_publish_mode>
      <service_request_writer_publish_mode>
        <kind>ASYNCHRONOUS_PUBLISH_MODE_QOS</kind>
      </service_request_writer_publish_mode>
    </discovery_config>
    <transport_builtin>
      <udp4>
        <message_size_max>1400</message_size_max>
```

```

    </udpv4>
    <udpv6>
      <message_size_max>1400</message_size_max>
    </udpv6>
    <udpv4_wan>
      <message_size_max>1400</message_size_max>
    </udpv4_wan>
  </transport_builtin>
</domain_participant_qos>

<datawriter_qos>
  <publish_mode>
    <kind>ASYNCHRONOUS_PUBLISH_MODE_QOS</kind>
  </publish_mode>
</datawriter_qos>
</qos_profile>

```

(See [50.2.3.3 QoS Profile Composition on page 914](#) for more information on QoS snippets in XML files.)

## 34.3.2 Reliable Reliability

If you use Best Effort reliability (see [47.21 RELIABILITY QosPolicy on page 845](#)), the application is not going to try to recover any lost DDS-level fragments, so if any fragments are lost, the *DataReader* will discard the entire sample. Depending on its size, the sample could have a lot of fragments, in which case the *DataReader* is more likely to lose a fragment (and therefore, the entire sample). By using Reliable [47.21 RELIABILITY QosPolicy on page 845](#), if a fragment is lost, *Connex* will try to recover it. This is why it's usually recommended to use Reliable reliability if you are using DDS-level fragmentation.

For more information, see the [47.21 RELIABILITY QosPolicy on page 845](#).

## 34.3.3 Asynchronous Publishing

DDS-level fragmentation requires asynchronous publication if you are using Reliable [47.21 RELIABILITY QosPolicy on page 845](#). Sending reliable samples larger than the transport's **message\_size\_max** requires asynchronous publication so that the fragmentation process can take place outside of the context of the thread that wrote the sample.

If you're using Best Effort reliability, samples larger than the **message\_size\_max** will be fragmented; however, this configuration (Best Effort, plus fragmentation) is not recommended because you're more likely to drop samples. The error "**COMMENDSrWriterService\_on\_Submessage:!write resend. Reliable large data requires asynchronous write**" comes from having a serialized sample that is greater than the transport's **message\_size\_max** while the [47.21 RELIABILITY QosPolicy on page 845](#) is set to **RELIABLE\_RELIABILITY\_QOS** without asynchronous publishing being enabled.

To fragment DDS packets while using Reliable reliability, set **kind** in the [47.20 PUBLISH\\_MODE QosPolicy \(DDS Extension\) on page 843](#) to **ASYNCHRONOUS\_PUBLISH\_MODE\_QOS**. With these

settings, *Connex* will use a separate thread to send the fragments. This will relieve your application thread from doing the fragmentation and sending work. For more information about the asynchronous publisher, see [46.1 ASYNCHRONOUS\\_PUBLISHER QoSPolicy \(DDS Extension\) on page 740](#).

It may also be necessary to set the builtin `PublicationBuiltinTopicData` and `SubscriptionBuiltinTopicData` *DataWriters*' publish mode to be asynchronous. This is done through the [44.3 DISCOVERY\\_CONFIG QoSPolicy \(DDS Extension\) on page 703](#) (see details in [34.3.5 Example below](#)). The most common cause of a large `PublicationBuiltinTopicData` or `SubscriptionBuiltinTopicData` sample is the serialized `TypeCode` or `TypeObject`, but you may also be sending a lot of properties (via the [47.19 PROPERTY QoSPolicy \(DDS Extension\) on page 837](#)) or have a large `ContentFilteredTopic` filter expression, among other variably sized fields, which could be leading to larger sample sizes. It may also be the case that the samples are not particularly large, but if you have set the `message_size_max` to be a small value to force DDS-level fragmentation, the samples sent by the builtin *DataWriters* may exceed this size and require fragmentation.

For more information on `TypeObjects`, see the following:

- [17.1.3.1 Sending Type Information on the Network on page 121](#)
- *Type Representation*, in the [RTI Connex Core Libraries Extensible Types Guide](#)
- [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QoSPolicy \(DDS Extension\) on page 714](#)

## 34.3.4 Flow Controllers

The asynchronous publish mode requires a `FlowController`. If no `FlowController` is defined, the default `FlowController` will be used. With the default `FlowController`, the `DATA_FRAGs` will be written as fast as the *DataWriter* can write them, which might overload the network or the *DataReaders*. See [34.4 FlowControllers \(DDS Extension\) on page 532](#).

An example on how to set the *DataWriter* to be asynchronous is shown below.

## 34.3.5 Example

The following example shows the QoS settings that do the following:

- Set the *DataWriter* to be asynchronous.
- Set the builtin *DataWriters* to be asynchronous.
- Enable Reliable [47.21 RELIABILITY QoSPolicy on page 845](#) on the *DataWriter* and *DataReader*. *DataWriters* are configured as reliable by default, so this is technically not required. *DataReaders* are configured for best effort communication by default, so enabling reliability on the *DataReader* is a required step in order for the *DataWriter* and *DataReader* to communicate reliably with each other. See [47.21 RELIABILITY QoSPolicy on page 845](#).

- Disable the shared memory transport (since our discussion thus far has focused on IP transports and the relationship between IP-layer fragmentation and DDS-layer fragmentation, not shared memory fragmentation).
- Set the maximum payload size for RTPS packets by configuring **message\_size\_max**.

```

<!-- Set the DataWriter to be asynchronous and reliable -->
<datawriter_qos>
  <publish_mode>
    <kind>ASYNCHRONOUS_PUBLISH_MODE_QOS</kind>
    <flow_controller_name>DEFAULT_FLOW_CONTROLLER_NAME</flow_controller_name>
  </publish_mode>
  <reliability>
    <kind>RELIABLE_RELIABILITY_QOS</kind>
  </reliability>
</datawriter_qos>

<!-- Set the DataReader to be reliable -->
<datareader_qos>
  <reliability>
    <kind>RELIABLE_RELIABILITY_QOS</kind>
  </reliability>
</datareader_qos>

```

## 34.3.6 Fragmentation Statistics

You can monitor fragmented (`DATA_FRAG`) messages via the [31.6.3 `DATA\_WRITER\_PROTOCOL\_STATUS` on page 399](#) and [40.7.3 `DATA\_READER\_PROTOCOL\_STATUS` on page 630](#), which are also visible through RTI Monitor (see [Chapter 59 RTI Monitoring Library on page 1126](#)).

## 34.4 FlowControllers (DDS Extension)

This section does not apply when using the separate add-on product, *Ada Language Support*, which does not support FlowControllers.

A FlowController is the object responsible for shaping the network traffic by determining when attached asynchronous *DataWriters* are allowed to write data. To configure a *DataWriter* to be asynchronous, see [47.20 `PUBLISH\_MODE` QoSPolicy \(DDS Extension\) on page 843](#).

You can use one of the built-in FlowControllers (and optionally modify their properties), create a custom FlowController by using the *DomainParticipant's* `create_flowcontroller()` operation (see [34.4.6 Creating and Deleting FlowControllers on page 543](#)), or create a custom FlowController by using the *DomainParticipant's* [47.19 `PROPERTY` QoSPolicy \(DDS Extension\) on page 837](#); see [34.4.5 Creating and Configuring Custom FlowControllers with Property QoS on page 541](#).

To use a FlowController, you provide its name in the *DataWriter's* [47.20 `PUBLISH\_MODE` QoSPolicy \(DDS Extension\) on page 843](#).

- **DDS\_DEFAULT\_FLOW\_CONTROLLER\_NAME**

By default, flow control is disabled. That is, the built-in `DDS_DEFAULT_FLOW_CONTROLLER_NAME` flow controller does not apply any flow control. Instead, it allows data to be sent asynchronously as soon as it is written by the *DataWriter*.

- **DDS\_FIXED\_RATE\_FLOW\_CONTROLLER\_NAME**

The `FIXED_RATE` flow controller shapes the network traffic by allowing data to be sent only once every second. Any accumulated DDS samples destined for the same destination are coalesced into as few network packets as possible.

- **DDS\_ON\_DEMAND\_FLOW\_CONTROLLER\_NAME**

The `ON_DEMAND` flow controller allows data to be sent only when you call the FlowController's `trigger_flow()` operation. With each trigger, all accumulated data since the previous trigger is sent (across all *Publishers* or *DataWriters*). In other words, the network traffic shape is fully controlled by the user. Any accumulated DDS samples destined for the same destination are

coalesced into as few network packets as possible.

This external trigger source is ideal for users who want to implement some form of closed-loop flow control or who want to only put data on the wire every so many DDS samples (e.g., with the number of DDS samples based on `NDDS_Transport_Property_t`'s `gather_send_buffer_count_max`).

The default property settings for the built-in FlowControllers are described in the API Reference HTML documentation.

DDS samples written by an asynchronous *DataWriter* are not sent in the context of the `write()` call. Instead, *Connex* puts the DDS samples in a queue for future processing and they are sent in the asynchronous publishing thread. (See [46.1 ASYNCHRONOUS\\_PUBLISHER QoSPolicy \(DDS Extension\) on page 740](#).) The FlowController associated with each asynchronous *DataWriter* determines when the DDS samples are actually sent.

Each FlowController maintains a separate FIFO queue for each unique destination (remote application). DDS samples written by asynchronous *DataWriters* associated with the FlowController are placed in the queues that correspond to the intended destinations of the DDS sample.

When tokens become available, a FlowController must decide which queue(s) to grant tokens first. This is determined by the FlowController's `scheduling_policy` property (see [Table 34.2 DDS\\_FlowControllerProperty\\_t](#)). Once a queue has been granted tokens, it is serviced by the asynchronous publishing thread. The queued up DDS samples will be coalesced and sent to the corresponding destination. The number of DDS samples sent depends on the data size and the number of tokens granted.

[Table 34.2 DDS\\_FlowControllerProperty\\_t](#) lists the properties for a FlowController.

**Table 34.2 DDS\_FlowControllerProperty\_t**

Type	Field Name	Description
DDS_FlowControllerSchedulingPolicy	scheduling_policy	Round robin, earliest deadline first, or highest priority first. See <a href="#">34.4.1 Flow Controller Scheduling Policies on the next page</a> .
DDS_FlowControllerTokenBucketProperty_t	token_bucket	See <a href="#">34.4.3 Token Bucket Properties on page 536</a> .

[Table 34.3 FlowController Operations](#) lists the operations available for a FlowController.

**Table 34.3 FlowController Operations**

Operation	Description	Reference
get_property	Get and Set the FlowController properties.	<a href="#">34.4.8 Getting/Setting Properties for a Specific FlowController on page 544</a>
set_property		
trigger_flow	Provides an external trigger to the FlowController.	<a href="#">34.4.9 Adding an External Trigger on page 545</a>
get_name	Returns the name of the FlowController.	<a href="#">34.4.10 Other FlowController Operations on page 545</a>
get_participant	Returns the <i>DomainParticipant</i> to which the FlowController belongs.	

### 34.4.1 Flow Controller Scheduling Policies

- **Round Robin**

(DDS\_RR\_FLOW\_CONTROLLER\_SCHED\_POLICY) Perform flow control in a round-robin (RR) fashion.

Whenever tokens become available, the FlowController distributes the tokens uniformly across all of its (non-empty) destination queues. No destinations are prioritized. Instead, all destinations are treated equally and are serviced in a round-robin fashion.

- **Earliest Deadline First**

(DDS\_EDF\_FLOW\_CONTROLLER\_SCHED\_POLICY) Perform flow control in an earliest-deadline-first (EDF) fashion.

A DDS sample's deadline is determined by the time it was written plus the latency budget of the *DataWriter* at the time of the write call (as specified in the DDS\_LatencyBudgetQosPolicy). The relative priority of a flow controller's destination queue is determined by the earliest deadline across all DDS samples it contains.

When tokens become available, the FlowController distributes tokens to the destination queues in order of their priority. In other words, the queue containing the DDS sample with the earliest deadline is serviced first. The number of tokens granted equals the number of tokens required to send the first DDS sample in the queue. Note that the priority of a queue may change as DDS samples are sent (i.e., removed from the queue). If a DDS sample must be sent to multiple destinations or two DDS samples have an equal deadline value, the corresponding destination queues are serviced in a round-robin fashion.

With the default **duration** of 0 in the LatencyBudgetQosPolicy, using an EDF\_FLOW\_CONTROLLER\_SCHED\_POLICY FlowController preserves the order in which you call **write()** across the *DataWriters* associated with the FlowController.

Since the `LatencyBudgetQosPolicy` is mutable, a DDS sample written second may contain an earlier deadline than the DDS sample written first if the `DDS_LatencyBudgetQosPolicy`'s **duration** is sufficiently decreased in between writing the two DDS samples. In that case, if the first DDS sample is not yet written (still in queue waiting for its turn), it inherits the priority corresponding to the (earlier) deadline from the second DDS sample.

In other words, the priority of a destination queue is always determined by the earliest deadline among all DDS samples contained in the queue. This priority inheritance approach is required in order to both honor the updated **duration** and to adhere to the *DataWriter* in-order data delivery guarantee.

- **Highest Priority First**

(`DDS_HPF_FLOW_CONTROLLER_SCHED_POLICY`) Perform flow control in an highest-priority-first (HPF) fashion.

**Note:** Prioritized DDS samples are not supported when using the Ada API. Therefore, the Highest Priority First scheduling policy is not supported when using this API.

The next destination queue to service is determined by the publication priority of the *DataWriter*, the channel of a multi-channel *DataWriter*, or individual DDS sample.

The relative priority of a flow controller's destination queue is determined by the highest publication priority of all the DDS samples it contains.

When tokens become available, the `FlowController` distributes tokens to the destination queues in order of their publication priority. The queue containing the DDS sample with the highest publication priority is serviced first. The number of tokens granted equals the number of tokens required to send the first DDS sample in the queue. Note that a queue's priority may change as DDS samples are sent (i.e., as they are removed from the queue). If a DDS sample must be sent to multiple destinations or two DDS samples have the same publication priority, the corresponding destination queues are serviced in a round-robin fashion.

This priority inheritance approach is required to both honor the designated publication priority and adhere to the *DataWriter*'s in-order data delivery guarantee.

See also: [34.4.4 Prioritized DDS Samples on page 538](#).

## 34.4.2 Managing Fast DataWriters When Using a FlowController

If a *DataWriter* is writing DDS samples faster than its attached `FlowController` can throttle, *Connex* may drop DDS samples on the writer's side. This happens because the DDS samples may be removed from the queue before the asynchronous publisher's thread has a chance to send them. To work around this problem, either:

- Use reliable communication to block the `write()` call and thereby throttle your application.
- Do not allow the queue to fill up in the first place.

The queue should be sized large enough to handle expected write bursts, so that no DDS samples are dropped. Then in steady state, the FlowController will smooth out these bursts and the queue will ideally have only one entry.

### 34.4.3 Token Bucket Properties

FlowControllers use a token-bucket approach for open-loop network flow control. The flow control characteristics are determined by the token bucket properties. The properties are listed in [Table 34.4 DDS\\_FlowControllerTokenBucketProperty\\_t](#); see the API Reference HTML documentation for their defaults and valid ranges.

**Table 34.4 DDS\_FlowControllerTokenBucketProperty\_t**

Type	Field Name	Description
DDS_Long	max_tokens	Maximum number of tokens than can accumulate in the token bucket. See <a href="#">34.4.3.1 max_tokens on the next page</a> .
DDS_Long	tokens_added_per_period	The number of tokens added to the token bucket per specified period. See <a href="#">34.4.3.2 tokens_added_per_period on the next page</a> .
DDS_Long	tokens_leaked_per_period	The number of tokens removed from the token bucket per specified period. See <a href="#">34.4.3.3 tokens_leaked_per_period on the next page</a> .
DDS_Duration_t	period	Period for adding tokens to and removing tokens from the bucket. See <a href="#">34.4.3.4 period on the next page</a> .
DDS_Long	bytes_per_token	Maximum number of bytes allowed to send for each token available. See <a href="#">34.4.3.5 bytes_per_token on the next page</a> .

Asynchronously published DDS samples are queued up and transmitted based on the token bucket flow control scheme. The token bucket contains tokens, each of which represents a number of bytes. DDS samples can be sent only when there are sufficient tokens in the bucket. As DDS samples are sent, tokens are consumed. The number of tokens consumed is proportional to the size of the data being sent. Tokens are replenished on a periodic basis.

The rate at which tokens become available and other token bucket properties determine the network traffic flow.

Note that if the same DDS sample must be sent to multiple destinations, separate tokens are required for each destination. Only when multiple DDS samples are destined to the same destination will they be coalesced and sent using the same token(s). In other words, each token can only contribute to a single network packet.

### 34.4.3.1 max\_tokens

The maximum number of tokens in the bucket will never exceed this value. Any excess tokens are discarded. This property value, combined with **bytes\_per\_token**, determines the maximum allowable data burst.

Use `DDS_LENGTH_UNLIMITED` to allow accumulation of an unlimited amount of tokens (and therefore potentially an unlimited burst size).

### 34.4.3.2 tokens\_added\_per\_period

A FlowController transmits data only when tokens are available. Tokens are periodically replenished. This field determines the number of tokens added to the token bucket with each periodic replenishment.

Available tokens are distributed to associated *DataWriters* based on the **scheduling\_policy**. Use `DDS_LENGTH_UNLIMITED` to add the maximum number of tokens allowed by **max\_tokens**.

### 34.4.3.3 tokens\_leaked\_per\_period

When tokens are replenished and there are sufficient tokens to send all DDS samples in the queue, this property determines whether any or all of the leftover tokens remain in the bucket.

Use `DDS_LENGTH_UNLIMITED` to remove all excess tokens from the token bucket once all DDS samples have been sent. In other words, no token accumulation is allowed. When new DDS samples are written after tokens were purged, the earliest point in time at which they can be sent is at the next periodic replenishment.

### 34.4.3.4 period

This field determines the period by which tokens are added or removed from the token bucket.

The special value `DDS_DURATION_INFINITE` can be used to create an on-demand FlowController, for which tokens are no longer replenished periodically. Instead, tokens must be added explicitly by calling the FlowController's **trigger\_flow()** operation. This external trigger adds **tokens\_added\_per\_period** tokens each time it is called (subject to the other property settings).

Once **period** is set to `DDS_DURATION_INFINITE`, it can no longer be reverted to a finite period.

### 34.4.3.5 bytes\_per\_token

This field determines the number of bytes that can actually be transmitted based on the number of tokens.

Tokens are always consumed in whole by each *DataWriter*. That is, in cases where **bytes\_per\_token** is greater than the DDS sample size, multiple DDS samples may be sent to the same destination using a single token (regardless of the **scheduling\_policy**).

Where fragmentation is required, the fragment size will be either (a) **bytes\_per\_token** or (b) the minimum of the **message\_size\_max** transport configuration across all transports installed with the *DataWriter*, whichever is less. See information about **message\_size\_max** in the desired transport, such as [Table 51.2 Properties for the Builtin UDPv4 Transport](#).

Use `DDS_LENGTH_UNLIMITED` to indicate that an unlimited number of bytes can be transmitted per token. In other words, a single token allows the recipient *DataWriter* to transmit all its queued DDS samples to a single destination. A separate token is required to send to each additional destination.

### 34.4.4 Prioritized DDS Samples

**Note:** This feature is not supported when using the Ada API.

The *Prioritized DDS Samples* feature allows you to prioritize traffic that is in competition for transmission resources. The granularity of this prioritization may be by *DataWriter*, by instance, or by individual DDS sample.

*Prioritized DDS Samples* can improve latency in the following cases:

- Low-Availability Links

With low-availability communication, unsent DDS samples may accumulate while the link is unavailable. When the link is restored, a large number of DDS samples may be waiting for transmission. High priority DDS samples will be sent first.

- Low-Bandwidth Links

With low-bandwidth communication, a temporary backlog may occur or the link may become congested with large DDS samples. High-priority DDS samples will be sent at the first available gap, between the fragments of a large low-priority DDS sample.

- Prioritized Topics

With limited bandwidth communication, some topics may be deemed to be of higher priority than others on an ongoing basis, and DDS samples written to some topics should be given precedence over others on transmission.

- High Priority Events

Due to external rules or content analysis (e.g., perimeter violation or identification as a threat), the priority of DDS samples is dynamically determined, and the priority assigned a given DDS sample will reflect the urgency of its delivery.

To configure a *DataWriter* to use prioritized DDS samples:

- Create a FlowController with the **scheduling\_policy** property set to *DDS\_HPF\_FLOW\_CONTROLLER\_SCHED\_POLICY*.
- Create a *DataWriter* with the [47.20 PUBLISH\\_MODE QosPolicy \(DDS Extension\) on page 843](#) **kind** set to *ASYNCHRONOUS* and **flow\_controller\_name** set to the name of the FlowController.

A single FlowController may perform traffic shaping for multiple *DataWriters* and multiple *DataWriter* channels. The FlowController's configuration determines how often publication resources are scheduled, how much data may be sent per period, and other transmission characteristics that determine the ultimate performance of prioritized DDS samples.

When working with prioritized DDS samples, you should use these operations, which allow you to specify priority:

- **write\_w\_params()** (see [31.8 Writing Data on page 410](#))
- **unregister\_instance\_w\_params()** (see [31.14.4 Unregistering Instances on page 429](#))
- **dispose\_w\_params()** (see [31.14.3 Disposing Instances on page 428](#))

If you use **write()**, **unregister()**, or **dispose()** instead of the **\_w\_params()** versions, the affected DDS sample is assigned priority 0 (undefined priority). If you are using a multi-channel *DataWriter* with a priority filter, and you have no channel for priority 0, the DDS sample will be discarded.

#### 34.4.4.1 Designating Priorities

For *DataWriters* and *DataWriter* channels, valid publication priority values are:

- *DDS\_PUBLICATION\_PRIORITY\_UNDEFINED*
- *DDS\_PUBLICATION\_PRIORITY\_AUTOMATIC*
- Positive integers excluding zero

For individual DDS samples, valid publication priority values are 0 and positive integers.

There are three ways to set the publication priority of a *DataWriter* or *DataWriter* channel:

1. For a *DataWriter*, publication priority is set in the **priority** field of its [47.20 PUBLISH\\_MODE QosPolicy \(DDS Extension\) on page 843](#). For a multi-channel *DataWriter* (see [47.16 MULTI\\_CHANNEL QosPolicy \(DDS Extension\) on page 830](#)), this value will be the default publication priority for any member channel that has not been assigned a specific value.

2. For a channel of a Multi-channel *DataWriter*, publication priority can be set in the *DataWriter*'s [47.16 MULTI\\_CHANNEL QosPolicy \(DDS Extension\) on page 830](#) in `channels[].priority`.
3. If a *DataWriter* or a channel of a Multi-channel *DataWriter* is configured for publication priority inheritance (DDS\_PUBLICATION\_PRIORITY\_AUTOMATIC), its publication priority is the highest priority among all the DDS samples currently in the publication queue. When using publication priority inheritance, the publication priorities of individual DDS samples are set by calling the `write_w_params()` operation, which takes a `priority` parameter.

The *effective* publication priority is determined from the interaction of the *DataWriter*, channel, and DDS sample publication priorities, as shown in [Table 34.5 Effective Publication Priority of Samples](#).

**Table 34.5 Effective Publication Priority of Samples**

	Priority Setting Combinations				
Writer Priority	Undefined	Don't care	AUTOMATIC	Don't care	Designated positive integer > 0
Channel Priority	Undefined	AUTOMATIC	Undefined	Designated positive integer > 0	Undefined
DDS Sample Priority	Don't care	Designated positive integer > 0	Designated positive integer > 0	Don't care	Don't care
Effective Priority	Lowest Priority	DDS Sample Priority <sup>1</sup>	DDS Sample Priority <sup>2</sup>	Channel Priority	Writer Priority

#### 34.4.4.2 Priority-Based Filtering

The configuration methods explained above are sufficient to create multiple *DataWriters*, each with its own assigned priority, all using the same *FlowController* configured for *publication priority*-based scheduling. Such a configuration is sufficient to assign different priorities to individual topics, but it does not allow different *publication priorities* to be assigned to published data *within a Topic*.

To assign different priorities to data within a *DataWriter*, you will need to use a Multi-channel *DataWriter* and configure the channels with different priorities. Configuring the publication priorities of *DataWriter* channels is explained above. To associate different priorities of data with different publication channels, configure the `channel[].filter_expression` in the *DataWriter*'s [47.16 MULTI\\_CHANNEL QosPolicy \(DDS Extension\) on page 830](#). The filtering criteria that is available for evaluation by each channel is determined by the filter type, which is configured with the *DataWriter*'s `filter_name` (also in the [47.16 MULTI\\_CHANNEL QosPolicy \(DDS Extension\) on page 830](#)).

<sup>1</sup>Highest sample priority among all DDS samples currently in the publication queue.

<sup>2</sup>Highest sample priority among all DDS samples currently in the publication queue.

For example, using the built-in SQL-based content filter allows channel membership to be determined based on the content of each DDS sample.

If you do not want to embed priority criteria within each DDS sample, you can use a built-in filter named `DDS_PRIFILTER_NAME` that uses the publication priority that is provided when you call `write_w_params()` (see [31.8 Writing Data on page 410](#)). The filter's expression syntax is:

```
@priority OP VAL
```

where OP can be `<`, `<=`, `>`, `>=`, `=`, or `<>` (standard relational operators), and VAL is a positive integer.

The filter supports multiple expressions, combined with the conjunctions AND and OR. You can use parentheses to disambiguate combinations of AND and OR in the same expression. For example:

```
@priority = 2 OR (@priority > 6 AND @priority < 10)
```

## 34.4.5 Creating and Configuring Custom FlowControllers with Property QoS

You can create and configure FlowControllers using the [47.19 PROPERTY QoS Policy \(DDS Extension\) on page 837](#). The properties must have a prefix of “`dds.flow_controller.token_bucket`”, followed by the name of the FlowController being created or configured. For example, if you want to create/configure a FlowController named **MyFC**, all the properties for **MyFC** should have the prefix “`dds.flow_controller.token_bucket.MyFC`”.

[Table 34.6 FlowController Properties](#) lists the properties that can be set for FlowControllers in the *DomainParticipant's* [47.19 PROPERTY QoS Policy \(DDS Extension\) on page 837](#). A FlowController with the name “`dds.flow_controller.token_bucket.<your flow controllername>`” will be implicitly created when at least one property using that prefix is specified. Then, to link a *DataWriter* to your FlowController, use “`dds.flow_controller.token_bucket.<your flow controllername>`” in the *DataWriter's* `publish_mode.flow_controller_name`.

**Table 34.6 FlowController Properties**

Property Name prefix with ‘ <code>dds.flow_controller.token_bucket.&lt;your flow controller name&gt;</code> ’	Property Value Description
<code>scheduling_policy</code>	Specifies the scheduling policy to be used. (See <a href="#">34.4.1 Flow Controller Scheduling Policies on page 534</a> ) May be: <code>DDS_RR_FLOW_CONTROLLER_SCHED_POLICY</code> <code>DDS_EDF_FLOW_CONTROLLER_SCHED_POLICY</code> <code>DDS_HPF_FLOW_CONTROLLER_SCHED_POLICY</code>
<code>token_bucket.max_tokens</code>	Maximum number of tokens than can accumulate in the token bucket. Use -1 for unlimited.

**Table 34.6 FlowController Properties**

Property Name prefix with 'dds.flow_controller.token_ bucket.' <your flow controller name>	Property Value Description
token_bucket.tokens_added_per_period	Number of tokens added to the token bucket per specified period. Use -1 for unlimited.
token_bucket.tokens_leaked_per_period	Number of tokens removed from the token bucket per specified period. Use -1 for unlimited.
token_bucket.period.sec	Period for adding tokens to and removing tokens from the bucket in seconds.
token_bucket.period.nanosec	Period for adding tokens to and removing tokens from the bucket in nanoseconds.
token_bucket.bytes_per_token	Maximum number of bytes allowed to send for each token available.

### 34.4.5.1 Example

The following example shows how to set FlowController properties.

```

<domain_participant_qos>
  <property>
    <value>
      <element>
        <name>
dds.flow_controller.token_bucket.MyFlowController.scheduling_policy
        </name>
        <value>DDS_RR_FLOW_CONTROLLER_SCHED_POLICY</value>
      </element>
      <element>
        <name>
dds.flow_controller.token_bucket.MyFlowController.token_bucket.period.sec
        </name>
        <value>100</value>
      </element>
      <element>
        <name>
dds.flow_controller.token_bucket.MyFlowController.token_bucket.period.nanosec
        </name>
        <value>0</value>
      </element>
      <element>
        <name>
dds.flow_controller.token_bucket.MyFlowController.token_bucket.tokens_added_per_period
        </name>
        <value>2</value>
      </element>
      <element>
        <name>
dds.flow_controller.token_bucket.MyFlowController.token_bucket.tokens_leaked_per_period
        </name>

```

```

        <value>2</value>
      </element>
    <element>
      <name>
dds.flow_controller.token_bucket.MyFlowController.token_bucket.bytes_per_token
      </name>
      <value>1024</value>
    </element>
  </value>
</property>
</domain_participant_qos>
<datawriter_qos>
  <publish_mode>
    <flow_controller_name>
      dds.flow_controller.token_bucket.MyFlowController
    </flow_controller_name>
    <kind>ASYNCHRONOUS_PUBLISH_MODE_QOS</kind>
  </publish_mode>
</datawriter_qos>

```

## 34.4.6 Creating and Deleting FlowControllers

(Note: in the Modern C++ API FlowControllers have reference semantics, see [Creating and Deleting Entities](#))

If you do not want to use one of the three built-in FlowControllers described in [34.4 FlowControllers \(DDS Extension\) on page 532](#), you can create your own with the *DomainParticipant*'s **create\_flow\_controller()** operation:

```

DDSFlowController* create_flowcontroller
  (const char * name,
   const DDS_FlowControllerProperty_t & property)

```

To associate a FlowController with a *DataWriter*, you set the FlowController's name in the [47.20 PUBLISH\\_MODE QosPolicy \(DDS Extension\) on page 843](#) (**flow\_controller\_name**).

A single FlowController may service multiple *DataWriters*, even if they belong to a different *Publisher*. The FlowController's **property** structure determines how the FlowController shapes the network traffic.

<b>name</b>	Name of the FlowController to create. A <i>DataWriter</i> is associated with a DDSFlowController by name. Limited to 255 characters.
<b>property</b>	Properties to be used for creating the FlowController. The special value DDS_FLOW_CONTROLLER_PROPERTY_DEFAULT can be used to indicate that the FlowController should be created with the default DDS_FlowControllerProperty_t set in the <i>DomainParticipant</i> .

**Note:** If you use DDS\_FLOW\_CONTROLLER\_PROPERTY\_DEFAULT, it is *not* safe to create the FlowController while another thread may be simultaneously calling **set\_default\_flowcontroller\_property()** or looking for that FlowController with **lookup\_flowcontroller()**.

To delete an existing FlowController, use the *DomainParticipant*'s **delete\_flowcontroller()** operation:

```
DDS_ReturnCode_t delete_flowcontroller (DDSFlowController * fc)
```

The FlowController must belong this the *DomainParticipant* and not have any attached *DataWriters* or the delete call will return an error (PRECONDITION\_NOT\_MET).

### 34.4.7 Getting/Setting Default FlowController Properties

To get the default DDS\_FlowControllerProperty\_t values, use this operation on the *DomainParticipant*:

```
DDS_ReturnCode_t get_default_flowcontroller_property  
(DDS_FlowControllerProperty_t & property)
```

The retrieved property will match the set of values specified on the last successful call to the *DomainParticipant*'s **set\_default\_flowcontroller\_property()**, or if the call was never made, the default values listed in DDS\_FlowControllerProperty\_t.

To change the default DDS\_FlowControllerProperty\_t values used when a new FlowController is created, use this operation on the *DomainParticipant*:

```
DDS_ReturnCode_t set_default_flowcontroller_property  
(const DDS_FlowControllerProperty_t & property)
```

The special value DDS\_FLOW\_CONTROLLER\_PROPERTY\_DEFAULT may be passed for the **property** to indicate that the default property should be reset to the default values the factory would use if **set\_default\_flowcontroller\_property()** had never been called.

**Note:** It is not safe to set the default FlowController properties while another thread may be simultaneously calling **get\_default\_flowcontroller\_property()**, **set\_default\_flowcontroller\_property()**, or **create\_flowcontroller()** with DDS\_FLOW\_CONTROLLER\_PROPERTY\_DEFAULT as the **qos** parameter. It is also not safe to get the default FlowController properties while another thread may be simultaneously calling **get\_default\_flowcontroller\_property()**.

### 34.4.8 Getting/Setting Properties for a Specific FlowController

To get the properties of a FlowController, use the FlowController's **get\_property()** operation:

```
DDS_ReturnCode_t DDSFlowController::get_property  
(struct DDS_FlowControllerProperty_t & property)
```

To change the properties of a FlowController, use the FlowController's **set\_property()** operation:

```
DDS_ReturnCode_t DDSFlowController::set_property  
(const struct DDS_FlowControllerProperty_t & property)
```

Once a FlowController has been instantiated, only its **token\_bucket** property can be changed. The **scheduling\_policy** is immutable. A new **token.period** only takes effect at the next scheduled token distribution time (as determined by its previous value).

The special value DDS\_FLOW\_CONTROLLER\_PROPERTY\_DEFAULT can be used to match the current default properties set in the *DomainParticipant*.

## 34.4.9 Adding an External Trigger

Typically, a FlowController uses an internal trigger to periodically replenish its tokens. The period by which this trigger is called is determined by the **period** property setting.

The **trigger\_flow()** function provides an additional, external trigger to the FlowController. This trigger adds **tokens\_added\_per\_period** tokens each time it is called (subject to the other property settings of the FlowController).

```
DDS_ReturnCode_t trigger_flow ( )
```

An on-demand FlowController can be created with a `DDS_DURATION_INFINITE` as **period**, in which case the only trigger source is external (i.e. the FlowController is solely triggered by the user on demand).

**trigger\_flow()** can be called on both a strict on-demand FlowController and a hybrid FlowController (internally and externally triggered).

## 34.4.10 Other FlowController Operations

If you have the FlowController object and need its name, call the FlowController's **get\_name()** operation:

```
const char* DDSFlowController::get_name( )
```

Conversely, if you have the name of the FlowController and need the FlowController object, call the *DomainParticipant's* **lookup\_flowcontroller()** operation:

```
DDSFlowController* lookup_flowcontroller (const char * name)
```

To get a FlowController's *DomainParticipant*, call the FlowController's **get\_participant()** operation:

```
DDSDomainParticipant* get_participant ( )
```

**Note:** It is not safe to lookup a FlowController description while another thread is creating that FlowController

## Chapter 35 Filtering Data

A `ContentFilteredTopic` creates a relationship between a *Topic*, also called the related topic, and user-specified filtering properties. The filtering properties consist of an expression and a set of parameters.

- The filter expression evaluates a logical expression on the data samples within a *Topic*. The filter expression is similar to the `WHERE` clause in a SQL expression.
- The parameters are strings that give values to the 'parameters' in the filter expression. There must be one parameter string for each parameter in the filter expression.

A `ContentFilteredTopic` is a type of topic description, and it can be used to when creating *DataReaders*. However, a `ContentFilteredTopic` is *not* an entity—it does not have *QoS*Policies or *Listeners*.

A `ContentFilteredTopic` relates to other entities in *Connex*t as follows:

- `ContentFilteredTopics` are used when creating *DataReaders*, not *DataWriters*.
- Multiple *DataReaders* can be created using the same `ContentFilteredTopic`.
- A `ContentFilteredTopic` belongs to (is created/deleted by) a *DomainParticipant*.
- A `ContentFilteredTopic` and *Topic* must belong to the same *DomainParticipant*.
- A `ContentFilteredTopic` can only be related to a single *Topic*.
- A *Topic* can be related to multiple `ContentFilteredTopics`.
- A `ContentFilteredTopic` can have the same name as a *Topic*, but `ContentFilteredTopics` must have unique names within the same *DomainParticipant*.
- A *DataReader* created with a `ContentFilteredTopic` will use the related *Topic*'s *QoS* and *Listeners*.

- Changing filter parameters on a `ContentFilteredTopic` causes *all* `DataReaders` using the same `ContentFilteredTopic` to see the change and propagate the change as part of endpoint discovery traffic.
- A `Topic` cannot be deleted as long as at least one `ContentFilteredTopic` that has been created with it exists.
- A `ContentFilteredTopic` cannot be deleted as long as at least one `DataReader` that has been created with the `ContentFilteredTopic` exists.

`ContentFilteredTopics` only enable you to filter data. They do not prevent *Entities* from communicating. To do that, see [16.3.5 Isolating DomainParticipants and Endpoints from Each Other on page 91](#).

## 35.1 Where Filtering is Applied—Publishing vs. Subscribing Side

Filtering may be performed on either side of the distributed application. (The `DataWriter` obtains the filter expression and parameters from the `DataReader` during discovery.)

When batching is enabled, content filtering is always done on the reader side.

*Connex* also supports network-switch filtering for multi-channel `DataWriters` (see [Multi-Channel DataWriters for High-Performance Filtering \(Chapter 36 on page 576\)](#)).

A `DataWriter` will automatically filter DDS data samples for a `DataReader` if *all* of the following are true; otherwise filtering is performed by the `DataReader`.

1. The `DataWriter` is filtering for no more than **`writer_resource_limits.max_remote_reader_filters`** `DataReaders` at the same time.
  - There is a resource-limit on the `DataWriter` called **`writer_resource_limits.max_remote_reader_filters`** (see [47.6 DATA\\_WRITER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 800](#)). This value can be from  $[0, (2^{31})-2]$  or `DDS_LENGTH_UNLIMITED` (default). 0 means do not filter any `DataReader`; 1 to  $(2^{31})-2$  means that the `DataWriter` will filter for up to the specified number of `DataReaders`, and the `DataWriter` will store the result of the filtering per sample per `DataReader`; `DDS_LENGTH_UNLIMITED` means that the `DataWriter` will filter for up to  $(2^{31})-2$  `DataReaders`, but in this case the `DataWriter` will not store the filtering result per sample per `DataReader`: if a sample is resent (such as due to a loss of reliable communication), the sample will be filtered again.
  - If a `DataWriter` is filtering **`max_remote_reader_filters`** `DataReaders` at the same time and a new filtered `DataReader` is created, then the newly created `DataReader` (**`max_remote_reader_filters + 1`**) is not filtered. Even if one of the first (**`max_remote_reader_filters`**) `DataReaders` is deleted, that already created `DataReader` (**`max_remote_reader_filters + 1`**) will *still* not be filtered. However, any subsequently created `DataReaders` will be filtered

as long as the number of *DataReaders* currently being filtered is not more than **writer\_resource\_limits.max\_remote\_reader\_filters**.

2. The *DataReader* is not subscribing to data using multicast.
3. There are no more than four matching *DataReaders* in the same locator (transport destination, for example IP address + port).

**Note:** *Connex* supports limited writer-side filtering if there are more than four matching *DataReaders* in the same locator. The middleware will not send any sample to a locator if the sample is filtered out by all the *DataReaders* receiving samples on that locator. However, if there is one *DataReader* to which the sample has to be sent, all the *DataReaders* on the locator will perform reader-side filtering for the incoming sample.

4. The *DataWriter* has infinite liveliness. (See [47.15 LIVELINESS QosPolicy on page 825](#).)
5. The *DataWriter* is *not* using an Asynchronous Publisher. (That is, the *DataWriter*'s [47.20 PUBLISH\\_MODE QosPolicy \(DDS Extension\) on page 843](#) **kind** is set to `DDS_SYNCHRONOUS_PUBLISHER_MODE_QOS`.)

**Note:** *Connex* supports limited writer-side filtering if asynchronous publishing is enabled. The middleware will not send any sample to a locator if the sample is filtered out by all the *DataReaders* receiving samples on that locator. However, if there is one *DataReader* to which the sample has to be sent, all the *DataReaders* on the locator will perform reader-side filtering for the incoming sample.

6. If you are using a custom filter (not the default one), it must be registered in the *DomainParticipant* of the *DataWriter* and the *DataReader*.
7. The *DataWriter* is not configured to use batching.

When batching is enabled, content filtering is always done on the reader side. See [47.2 BATCH QosPolicy \(DDS Extension\) on page 773](#).

## 35.2 Creating ContentFilteredTopics

To create a *ContentFilteredTopic* that uses the default SQL filter, use the *DomainParticipant*'s **create\_contentfilteredtopic()** operation:

```
DDS_ContentFilteredTopic *create_contentfilteredtopic(
    const char * name,
    const DDS_Topic * related_topic,
    const char * filter_expression,
    const DDS_StringSeq & expression_parameters)
```

Or, to use a custom filter or the builtin `STRINGMATCH` filter (see [35.6 STRINGMATCH Filter Expression Notation on page 564](#)), use the **create\_contentfilteredtopic\_with\_filter()** variation:

```
DDS_ContentFilteredTopic *create_contentfilteredtopic_with_filter(
    const char * name,
    DDS_Topic * related_topic,
    const char * filter_expression,
```

```
const DDS_StringSeq & expression_parameters,
const char * filter_name = DDS_SQLFILTER_NAME)
```

Where:

<b>name</b>	Name of the ContentFilteredTopic. Note that it <i>is</i> legal for a ContentFilteredTopic to have the same name as a Topic in the same <i>DomainParticipant</i> , but a ContentFilteredTopic cannot have the same name as another ContentFilteredTopic in the same <i>DomainParticipant</i> . This parameter cannot be NULL.
<b>related_topic</b>	The related Topic to be filtered. The related topic must be in the same <i>DomainParticipant</i> as the ContentFilteredTopic. This parameter cannot be NULL. The same related topic can be used in many different ContentFilteredTopics.
<b>filter_expression</b>	A logical expression on the contents on the Topic. If the expression evaluates to TRUE, a DDS sample is received; otherwise it is discarded. This parameter cannot be NULL. The notation for this expression depends on the filter that you are using (specified by the <b>filter_name</b> parameter). See <a href="#">35.5 SQL Filter Expression Notation on page 555</a> and <a href="#">35.6 STRINGMATCH Filter Expression Notation on page 564</a> . The <b>filter_expression</b> can be changed with <b>set_expression()</b> ( <a href="#">35.4.2 Setting an Expression's Filter and Parameters on page 553</a> ).
<b>expression_parameters</b>	A string sequence of filter expression parameters. Each parameter corresponds to a positional argument in the filter expression: element 0 corresponds to positional argument 0, element 1 to positional argument 1, and so forth.  The <b>expression_parameters</b> can be changed with <b>set_expression_parameters()</b> or <b>set_expression()</b> ( <a href="#">35.4.2 Setting an Expression's Filter and Parameters on page 553</a> ), <b>append_to_expression_parameter()</b> ( <a href="#">35.4.3 Appending a String to an Expression Parameter on page 554</a> ) and <b>remove_from_expression_parameter()</b> ( <a href="#">35.4.4 Removing a String from an Expression Parameter on page 554</a> ).
<b>filter_name</b>	Name of the content filter to use for filtering. The filter must have been previously registered with the <i>DomainParticipant</i> (see <a href="#">35.9.2 Registering a Custom Filter on page 568</a> ). There are two builtin filters, DDS_SQLFILTER_NAME <sup>1</sup> (the default filter) and DDS_STRINGMATCHFILTER_NAME—these are automatically registered.  To use the STRINGMATCH filter, call <b>create_contentfilteredtopic_with_filter()</b> with "DDS_STRINGMATCHFILTER_NAME" as the <b>filter_name</b> . STRINGMATCH filter expressions have the syntax: <b>&lt;field name&gt; MATCH &lt;string pattern&gt;</b> (see <a href="#">35.6 STRINGMATCH Filter Expression Notation on page 564</a> ). <sup>2</sup>

<sup>1</sup> In the Java API, you can access the names of the builtin filters by using `DomainParticipant.SQLFILTER_NAME` and `DomainParticipant.STRINGMATCHFILTER_NAME`. In the C# API, they can be found in the `Filter` class.

<sup>2</sup> In the Java API, you can access the names of the builtin filters by using `DomainParticipant.SQLFILTER_NAME` and `DomainParticipant.STRINGMATCHFILTER_NAME`. In the C# API, they can be found in the `Filter` class.

**To summarize:**

- To use the builtin default SQL filter:
  - Call `create_contentfilteredtopic()`
  - See [35.5 SQL Filter Expression Notation on page 555](#)
- To use the builtin STRINGMATCH filter:
  - Call `create_contentfilteredtopic_with_filter()`, setting the `filter_name` to `DDS_STRINGMATCHFILTER_NAME`
  - See [35.6 STRINGMATCH Filter Expression Notation on page 564](#)
- To use a custom filter:
  - Call `create_contentfilteredtopic_with_filter()`, setting the `filter_name` to a registered custom filter

Be careful with memory management of the string sequence in some of the ContentFilteredTopic APIs. See the **String Support** section in the API Reference HTML documentation (within the **Infrastructure** module) for details on sequences.

### 35.2.1 Creating ContentFilteredTopics for Built-in DDS Types

To create a ContentFilteredTopic for a built-in DDS type (see [17.2 Built-in Data Types on page 121](#)), use the standard *DomainParticipant* operations, `create_contentfilteredtopic()` or `create_contentfilteredtopic_with_filter`.

The field names used in the filter expressions for the built-in SQL (see [35.5 SQL Filter Expression Notation on page 555](#)) and StringMatch filters (see [35.6 STRINGMATCH Filter Expression Notation on page 564](#)) must correspond to the names provided in the IDL description of the built-in DDS types.

**ContentFilteredTopic Creation Examples:**

For simplicity, error handling is not shown in the following examples.

**C Example:**

```

DDS_Topic * topic = NULL;
DDS_ContentFilteredTopic * contentFilteredTopic = NULL;
struct DDS_StringSeq parameters = DDS_SEQUENCE_INITIALIZER;
/* Create a string ContentFilteredTopic */
topic = DDS_DomainParticipant_create_topic(
    participant, "StringTopic",
    DDS_StringTypeSupport_get_type_name(),
    &DDS_TOPIC_QOS_DEFAULT, NULL,
    DDS_STATUS_MASK_NONE);
contentFilteredTopic =
    DDS_DomainParticipant_create_contentfilteredtopic(
    participant,
    "StringContentFilteredTopic",
    topic,
    "value = 'Hello World!'", &parameters);

```

**Traditional C++ Example with Namespaces:**

```

using namespace DDS;
...
/* Create a String ContentFilteredTopic */
Topic * topic = participant->create_topic(
    "StringTopic",
    StringTypeSupport::get_type_name(),
    TOPIC_QOS_DEFAULT,
    NULL, STATUS_MASK_NONE);
StringSeq parameters;
ContentFilteredTopic * contentFilteredTopic =
    participant->create_contentfilteredtopic(
    "StringContentFilteredTopic", topic,
    "value = 'Hello World!'", parameters);

```

**Modern C++ Example:**

```

using dds::core::StringTopicType;

dds::topic::Topic<StringTopicType> topic(participant, "StringTopic");
dds::topic::ContentFilteredTopic<StringTopicType> content_filtered_topic(
    topic,
    "StringContentFilteredTopic",
    dds::topic::Filter("value = 'Hello World!'"));

```

**C# Example:**

```

using Rti.Dds.Domain;
using Rti.Dds.Topics;
using Rti.Types.Builtin;
...
var topic = participant.CreateTopic<StringTopicType>("StringTopic");
var filter = new Filter("value = 'Hello World!'");
participant.CreateContentFilteredTopic(
    "StringContentFilteredTopic",
    topic,
    filter);

```

**Java Example:**

```
import com.rti.dds.type.builtin.*;
...
/* Create a String ContentFilteredTopic */
Topic topic = participant.create_topic(
    "StringTopic", StringTypeSupport.get_type_name(),
    DomainParticipant.TOPIC_QOS_DEFAULT,
    null, StatusKind.STATUS_MASK_NONE);
StringSeq parameters = new StringSeq();
ContentFilteredTopic contentFilteredTopic =
    participant.create_contentfilteredtopic(
        "StringContentFilteredTopic", topic,
        "value = 'Hello World!'", parameters);
```

## 35.3 Deleting ContentFilteredTopics

To delete a ContentFilteredTopic, use the *DomainParticipant's* **delete\_contentfilteredtopic()** operation:

Make sure no *DataReaders* are using the ContentFilteredTopic. (If this is not true, the operation returns **PRECONDITION\_NOT\_MET**.)

Delete the ContentFilteredTopic by using the *DomainParticipant's* **delete\_contentfilteredtopic()** operation.

```
DDS_ReturnCode_t delete_contentfilteredtopic
    (DDSContentFilteredTopic * a_contentfilteredtopic)
```

## 35.4 Using a ContentFilteredTopic

Once you've created a ContentFilteredTopic, you can use the operations listed in [Table 35.1 ContentFilteredTopic Operations](#).

**Table 35.1 ContentFilteredTopic Operations**

Operation	Description	Reference
append_to_expression_parameter	Concatenates a string value to the input expression parameter	<a href="#">35.4.3 Appending a String to an Expression Parameter on page 554</a>
get_expression_parameters	Gets the expression parameters.	<a href="#">35.4.1 Getting the Current Expression Parameters on the next page</a>
get_filter_expression	Gets the expression.	<a href="#">35.4.5 Getting the Filter Expression on page 554</a>
get_related_topic	Gets the related Topic.	<a href="#">35.4.6 Getting the Related Topic on page 555</a>
narrow	Casts a DDS_TopicDescription pointer to a ContentFilteredTopic pointer.	<a href="#">35.4.7 'Narrowing' a ContentFilteredTopic to a TopicDescription on page 555</a>
remove_from_expression_parameter	Removes a string value from the input expression parameter	<a href="#">35.4.4 Removing a String from an Expression Parameter on page 554</a>

Table 35.1 ContentFilteredTopic Operations

Operation	Description	Reference
set_expression	Changes the filter expression and parameters.	<a href="#">35.4.2 Setting an Expression's Filter and Parameters below</a>
set_expression_parameters	Changes the expression parameters.	

### 35.4.1 Getting the Current Expression Parameters

To get the expression parameters, use the ContentFilteredTopic's `get_expression_parameters()` operation:

```
DDS_ReturnCode_t get_expression_parameters(struct DDS_StringSeq & parameters)
```

Where:

- parameters** The filter expression parameters.
- The memory for the strings in this sequence is managed as described in the **String Support** section of the API Reference HTML documentation (within the **Infrastructure** module). In particular, be careful to avoid a situation in which *Connex* allocates a string on your behalf and you then reuse that string in such a way that *Connex* believes it to have more memory allocated to it than it actually does. This parameter cannot be NULL.

This operation gives you the expression parameters that were specified on the last successful call to `set_expression_parameters()` or `set_expression()`, or if they were never called, the parameters specified when the ContentFilteredTopic was created.

### 35.4.2 Setting an Expression's Filter and Parameters

To change the filter expression and expression parameters associated with a ContentFilteredTopic:

```
DDS_ReturnCode set_expression(
    const char * expression,
    const struct DDS_StringSeq & parameters)
```

To change just the expression parameters (not the filter expression):

```
DDS_ReturnCode_t set_expression_parameters(const struct DDS_StringSeq & parameters)
```

Where:

- expression** The new expression to be set in the ContentFilteredTopic.
- parameters** The filter expression parameters. Each element in the parameter sequence corresponds to a positional parameter in the filter expression. When using the default `DDS_SQLFILTER_NAME`, parameter strings are automatically converted to the member type. For example, "4" is converted to the integer 4. This parameter cannot be NULL.

The ContentFilteredTopic's operations do not manage the sequences; you must ensure that the parameter sequences are valid. Please refer to the **String Support** section in the API Reference HTML documentation (within the Infrastructure module) for details on sequences.

### 35.4.3 Appending a String to an Expression Parameter

To concatenate a string to an expression parameter, use the ContentFilteredTopic's **append\_to\_expression\_parameter()** operation:

```
DDS_ReturnCode_t append_to_expression_parameter(const DDS_Long index, const char* value);
```

When using the STRINGMATCH filter, **index** must be 0.

This function is only intended to be used with the builtin SQL and STRINGMATCH filters. This function can be used in expression parameters associated with MATCH operators (see [35.5.5 SQL Extension: Regular Expression Matching on page 560](#)) to add a pattern to the match pattern list. For example, if **filter\_expression** is:

```
symbol MATCH 'IBM'
```

Then **append\_to\_expression\_parameter(0, "MSFT")** would generate the expression:

```
symbol MATCH 'IBM,MSFT'
```

### 35.4.4 Removing a String from an Expression Parameter

To remove a string from an expression parameter use the ContentFilteredTopic's **remove\_from\_expression\_parameter()** operation:

```
DDS_ReturnCode_t remove_from_expression_parameter(const DDS_Long index, const char* value)
```

When using the STRINGMATCH filter, **index** must be 0.

This function is only intended to be used with the builtin SQL and STRINGMATCH filters. It can be used in expression parameters associated with MATCH operators (see [35.5.5 SQL Extension: Regular Expression Matching on page 560](#)) to remove a pattern from the match pattern list. For example, if **filter\_expression** is:

```
symbol MATCH 'IBM,MSFT'
```

Then **remove\_from\_expression\_parameter(0, "IBM")** would generate the expression:

```
symbol MATCH 'MSFT'
```

### 35.4.5 Getting the Filter Expression

To get the filter expression that was specified when the ContentFilteredTopic was created or when **set\_expression()** was used:

```
const char* get_filter_expression ()
```

## 35.4.6 Getting the Related Topic

To get the related *Topic* that was specified when the `ContentFilteredTopic` was created:

```
DDS_Topic * get_related_topic ()
```

## 35.4.7 ‘Narrowing’ a `ContentFilteredTopic` to a `TopicDescription`

To safely cast a `DDS_TopicDescription` pointer to a `ContentFilteredTopic` pointer, use the `ContentFilteredTopic`’s `narrow()` operation:

```
DDS_TopicDescription* narrow ()
```

## 35.5 SQL Filter Expression Notation

A SQL filter expression is similar to the **WHERE** clause in SQL. The SQL expression format provided by *Connex* also supports the **MATCH** operator as an extended operator (see [35.5.5 SQL Extension: Regular Expression Matching on page 560](#)).

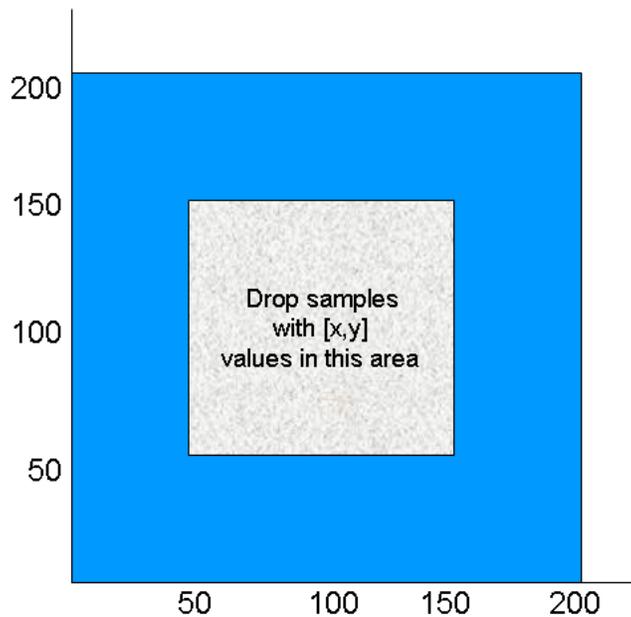

The following sections provide more information:

- [35.5.1 Example SQL Filter Expressions below](#)
- [35.5.2 SQL Grammar on page 557](#)
- [35.5.3 Token Expressions on page 558](#)
- [35.5.4 Type Compatibility in the Predicate on page 559](#)
- [35.5.5 SQL Extension: Regular Expression Matching on page 560](#)
- [35.5.6 Composite Members on page 561](#)
- [35.5.7 Strings on page 562](#)
- [35.5.8 Enumerations on page 562](#)
- [35.5.9 Pointers on page 562](#)
- [35.5.10 Arrays on page 562](#)
- [35.5.12 Sequences on page 564](#)

### 35.5.1 Example SQL Filter Expressions

Assume that you have a *Topic* with two floats, X and Y, which are the coordinates of an object moving inside a rectangle measuring 200 x 200 units. This object moves quite a bit, generating lots of DDS samples that you are not interested in. Instead you only want to receive DDS samples *outside* the middle of the rectangle, as seen in [Figure 35.1: Filtering Example on the next page](#). That is, you want to filter *out* data points in the gray box.

Figure 35.1: Filtering Example

The filter expression would look like this (remember the expression is written so that DDS samples that we *do* want will *pass*):

```
"(X < 50 or X > 150) and (Y < 50 or Y > 150)"
```

Suppose you would like the ability to adjust the coordinates that are considered outside the acceptable range (changing the size of the gray box). You can achieve this by changing the whole filter expression, using `set_expression()`, or by using filter parameters. The expression can be written using filter parameters as follows:

```
"(X < %0 or X > %1) and (Y < %2 or Y > %3)"
```

Recall that when you create a `ContentFilteredTopic` (see [35.2 Creating ContentFilteredTopics on page 548](#)), you pass a `expression_parameters` string sequence as one of the parameters. Each element in the string sequence corresponds to one argument.

See the **String** and **Sequence Support** sections of the API Reference HTML documentation (from the **Modules** page, select **RTI Connex API Reference, Infrastructure Module**).

In C++, the filter parameters could be assigned like this:

```
FilterParameter[0] = "50";
FilterParameter[1] = "150";
FilterParameter[2] = "50";
FilterParameter[3] = "150";
```

With these parameters, the filter expression is identical to the first approach. However, it is now possible to change the parameters by calling `set_expression_parameters()`. For example, perhaps you decide that you only want to see data points where  $X < 10$  or  $X > 190$ . To make this change:

```
FilterParameter[0] = 10
FilterParameter[1] = 190
set_expression_parameters(...)
```

The new filter parameters will affect all *DataReaders* that have been created with this *ContentFilteredTopic*.

## 35.5.2 SQL Grammar

This section describes the subset of SQL syntax, in Backus–Naur Form (BNF), that you can use to form filter expressions.

The following notational conventions are used:

*NonTerminals* are typeset in italics.

'Terminals' are quoted and typeset in a fixed-width font. They are written in upper case in most cases in the BNF-grammar below, but should be case insensitive.

**TOKENS** are typeset in bold.

The notation (element // ',') represents a non-empty, comma-separated list of elements.

```
FilterExpression ::= Condition
Condition      ::= Predicate
                | Condition 'AND' Condition
                | Condition 'OR' Condition
                | 'NOT' Condition
                | '(' Condition ')'
Predicate     ::= ComparisonPredicate
                | BetweenPredicate
ComparisonPredicate ::= ComparisonTerm RelOp ComparisonTerm
ComparisonTerm    ::= FieldIdentifier
                | Parameter
BetweenPredicate  ::= FieldIdentifier 'BETWEEN' Range
                | FieldIdentifier 'NOT BETWEEN' Range
FieldIdentifier   ::= FIELDNAME
                | IDENTIFIER
RelOp            ::= '=' | '>' | '>=' | '<' | '<=' | '<>' | 'LIKE' | 'MATCH'
Range           ::= Parameter 'AND' Parameter
Parameter       ::= INTEGERVALUE
                | CHARVALUE
                | FLOATVALUE
                | STRING
                | ENUMERATEDVALUE
                | BOOLEANVALUE
                | NULLVALUE
```

| PARAMETER

### 35.5.3 Token Expressions

The syntax and meaning of the tokens used in SQL grammar is described as follows:

**IDENTIFIER**—An identifier for a FIELDNAME, defined as any series of characters 'a', ..., 'z', 'A', ..., 'Z', '0', ..., '9', '\_' but may *not* start with a digit.

```
IDENTIFIER: LETTER (PART_LETTER)*
```

where LETTER: [ "A"- "Z", "\_", "a"- "z" ] PART\_LETTER: [ "A"- "Z", "\_", "a"- "z", "0"- "9" ]

**FIELDNAME**—A reference to a field in the data structure. A dot '.' is used to navigate through nested structures. The number of dots that may be used in a FIELDNAME is unlimited. The FIELDNAME can refer to fields at any depth in the data structure. The names of the field are those specified in the IDL definition of the corresponding structure, which may or may not match the fieldnames that appear on the language-specific (e.g., C/C++, Java) mapping of the structure. To reference the n+1 element in an array or sequence, use the notation '[n]', where n is a natural number (zero included).

FIELDNAME must resolve to a primitive IDL type; that is boolean, octet, uint16, uint32, uint64, float double, char, wchar, string, wstring, or enum.

```
FIELDNAME: FieldNamePart ( "." FieldNamePart )*
```

where FieldNamePart : IDENTIFIER ( "[" Index "]" )\* Index > : ([ "0"- "9" ])+ | [ "0x", "0X" ] ([ "0"- "9", "A"- "F", "a"- "f" ])+

Primitive IDL types referenced by FIELDNAME are treated as different types in Predicate according to the following table:

Predicate Data Type	IDL Type
BOOLEANVALUE	boolean
INTEGERVALUE	octet, uint16, uint32, uint64
FLOATVALUE	float, double
CHARVALUE	char, wchar
STRING	string, wstring
ENUMERATEDVALUE	enum

**TOPICNAME**—An identifier for a topic, and is defined as any series of characters 'a', ..., 'z', 'A', ..., 'Z', '0', ..., '9', '\_' but may *not* start with a digit.

```
TOPICNAME : IDENTIFIER
```

**INTEGERVALUE**—Any series of digits, optionally preceded by a plus or minus sign, representing a decimal integer value within the range of the system. 'L' or 'l' must be used for int64 (long long), oth-

erwise int32 (long) is assumed. A hexadecimal number is preceded by **0x** and must be a valid hexadecimal expression.

```
INTEGERVALUE : ([ "+", "-" ])? ([ "0"-"9" ])+ [ ("L", "l") ]?
              | ([ "+", "-" ])? [ "0x", "0X" ] ([ "0"-"9",
              "A"-"F", "a"-"f" ])+ [ ("L", "l") ]?
```

**CHARVALUE**—A single character enclosed between single quotes.

```
CHARVALUE : "'" (~["'"])? "'"
```

**FLOATVALUE**—Any series of digits, optionally preceded by a plus or minus sign and optionally including a floating point (.). 'F' or 'f' must be used for float, otherwise double is assumed. A power-of-ten expression may be postfixed, which has the syntax *en* or *En*, where *n* is a number, optionally preceded by a plus or minus sign.

```
FLOATVALUE : ([ "+", "-" ])? ([ "0"-"9" ])* ( "." )? ([ "0"-"9" ])+
            ( EXPONENT )? [ ("F", "f") ]?
```

where EXPONENT: [ "e", "E" ] ([ "+", "-" ])? ([ "0"-"9" ])+

**STRING**—Any series of characters encapsulated in single quotes, except the single quote itself.

```
STRING : "'" (~["'"])* "'"
```

**ENUMERATEDVALUE**—A reference to a value declared within an enumeration. Enumerated values consist of the name of the enumeration label enclosed in single quotes. The name used for the enumeration label must correspond to the label names specified in the IDL definition of the enumeration.

```
ENUMERATEDVALUE : "'" [ "A" - "Z", "a" - "z" ]
                [ "A" - "Z", "a" - "z", "_", "0" - "9" ]* "'"
```

**BOOLEANVALUE**—Can either be **TRUE** or **FALSE**, and is case insensitive.

```
BOOLEANVALUE : [ "TRUE", "FALSE" ]
```

**NULLVALUE**—Can be null, and is case insensitive.

```
NULLVALUE : "null"
```

**PARAMETER**—Takes the form *%n*, where *n* represents a natural number (zero included) smaller than 100. It refers to the (n + 1)th argument in the given context. This argument can only be in primitive type value format. It cannot be a FIELDNAME.

```
PARAMETER : "%" ([ "0"-"9" ])+
```

## 35.5.4 Type Compatibility in the Predicate

As seen in [Table 35.2 Valid Type Comparisons](#), only certain combinations of type comparisons are valid in the Predicate.

**Table 35.2 Valid Type Comparisons**

	BOOLEAN VALUE	INTEGER VALUE	FLOAT VALUE	CHAR VALUE	STRING	ENUMERATED VALUE
BOOLEAN	YES					
INTEGERVALUE		YES	YES			
FLOATVALUE		YES	YES			
CHARVALUE				YES	YES	YES
STRING				YES	YES <sup>1</sup>	YES
ENUMERATED VALUE		YES		YES <sup>2</sup>	YES <sup>3</sup>	YES <sup>4</sup>

### 35.5.5 SQL Extension: Regular Expression Matching

The relational operator **MATCH** may only be used with string fields. The right-hand operator is a string pattern. A string pattern specifies a template that the left-hand field must match.

**MATCH** is case-sensitive. The following characters have special meaning, unless escaped by the escape character: `, \ / ? * [ ] - ^ ! \ %`.

The pattern allows limited "wild card" matching under the rules in [Table 35.3 Wild Card Matching](#).

The syntax is similar to the POSIX® **fnmatch** syntax. (See <http://www.opengroup.org/onlinepubs/000095399/functions/fnmatch.html>.) Some example expressions include:

This expression evaluates to TRUE if the value of **symbol** is equal to **NASDAQ/MSFT**:

```
symbol MATCH 'NASDAQ/MSFT'
```

This expression evaluates to TRUE if the value of **symbol** is equal to **NASDAQ/IBM** or **NASDAQ/MSFT**:

<sup>a</sup>See [35.5.5 SQL Extension: Regular Expression Matching](#) below.

<sup>2</sup>Because of the formal notation of the Enumeration values, they are compatible with string and char literals, but they are not compatible with string or char variables, i.e., "MyEnum='EnumValue'" is correct, but "MyEnum=MyString" is not allowed.

<sup>3</sup>Because of the formal notation of the Enumeration values, they are compatible with string and char literals, but they are not compatible with string or char variables, i.e., "MyEnum='EnumValue'" is correct, but "MyEnum=MyString" is not allowed.

<sup>4</sup>Only for same-type Enums.

```
symbol MATCH 'NASDAQ/IBM,NASDAQ/MSFT'
```

This expression evaluates to TRUE if the value of **symbol** is equal to **NASDAQ** and starts with a letter between M and Y:

```
symbol MATCH 'NASDAQ/[M-Y]*'
```

**Table 35.3 Wild Card Matching**

Character	Meaning
,	A , separates a list of alternate patterns. The field string is matched if it matches one or more of the patterns.
/	A / in the pattern string matches a / in the field string. It separates a sequence of mandatory substrings.
?	A ? in the pattern string matches any single non-special characters in the field string.
*	A * in the pattern string matches 0 or more non-special characters in field string.
%	This special character is used to designate filter expression parameters.
\	Escape character for special characters.
[charlist]	Matches any one of the characters in charlist.
[!charlist] or [^charlist]	(Not supported) Matches any one of the characters <i>not</i> in charlist.
[s-e]	Matches any character from <b>s</b> to <b>e</b> , inclusive.
[!s-e] or [^s-e]	(Not supported) Matches any character <i>not</i> in the interval <b>s</b> to <b>e</b> .

**Note:** To use special characters as regular characters in regular expressions, you must escape them using the character '\'. For example, 'A[' is considered a malformed expression and the result is undefined.

## 35.5.6 Composite Members

Any member can be used in the filter expression, with the following exceptions:

- 128-bit floating point numbers (long doubles) are not supported
- bitfields are not supported
- **LIKE** is not supported

Composite members are accessed using the familiar dot notation, such as "**x.y.z > 5**". For unions, the notation is special due to the nature of the IDL union type.

On the publishing side, you can access the union discriminator with **myunion.\_d** and the actual member with **myunion.\_u.my member**. If you want to use a ContentFilteredTopic on the subscriber side and filter a DDS sample with a top-level union, you can access the union discriminator directly with **\_d** and the actual member with **my member** in the filter expression.

## 35.5.7 Strings

The filter expression and parameters can use IDL strings. String constants must appear between single quotation marks (').

For example:

```
" fish = 'salmon' "
```

Strings used as parameter values must contain the enclosing quotation marks (') within the parameter value; do not place the quotation marks within the expression statement. For example, the expression " symbol MATCH %0 " with parameter 0 set to " 'IBM' " is legal, whereas the expression " symbol MATCH '%0' " with parameter 0 set to " IBM " will not compile.

## 35.5.8 Enumerations

A filter expression can use enumeration values, such as GREEN, instead of the numerical value. For example, if x is an enumeration of GREEN, YELLOW and RED, the following expressions are valid:

```
"x = 'GREEN'"
"x < 'RED'"
```

## 35.5.9 Pointers

Pointers can be used in filter expressions and are automatically dereferenced to the correct value.

For example:

```
struct Point {
    int32 x;
    int32 y;
};
struct Rectangle {
    Point *u_l;
    Point *l_r;
};
```

The following expression is valid on a *Topic* of type Rectangle:

```
"u_l.x > l_r.x"
```

## 35.5.10 Arrays

Arrays are accessed with the familiar [] notation.

For example:

```
struct ArrayType {
    int32 value[255][5];
};
```

The following expression is valid on a *Topic* of type ArrayType:

```
"value[244][2] = 5"
```

In order to compare an array of bytes (octets in IDL), instead of comparing each individual element of the array using `[]` notation, *Connex* provides a helper function, `hex()`. The `hex()` function can be used to represent an array of bytes (octets in IDL). To use the `hex()` function, use the notation `&hex()` and pass the byte array as a sequence of hexadecimal values.

For example:

```
&hex (07 08 09 0A 0B 0c 0D 0E 0F 10 11 12 13 14 15 16)
```

Here the leftmost-pair represents the byte at index 0.

**Note:** If the length of the octet array represented by the `hex()` function does not match the length of the field being compared, it will result in a compilation error.

For example:

```
struct ArrayType {
    octet value[2];
};
```

The following expression is valid:

```
"value = &hex(12 0A)"
```

## 35.5.11 Optional Members

SQL filter expressions can refer to optional members. The syntax is the same as for any other member.

For example, given the type `MyType`:

```
struct Foo {
    string text;
};
struct MyType {
    @optional int32 optional_member1;
    @optional Foo optional_member2;
    int32 non_optional_member;
};
```

These are valid expressions:

```
"optional_member1 = 1 AND optional_member2.text = 'hello' AND non_optional_member = 2"
"optional_member1 = null AND optional_member2.text <> null"
```

Any comparison involving an optional member (`=`, `<>`, `<`, or `>`) evaluates to false if the member is unset.

For example, both `"optional_member1 <> 1"` and `"optional_member1 = 1"` will evaluate to false if `optional_member1` is unset; however `"optional_member1 = 1 OR non_optional_member = 1"` will be true if `non_optional_member` is equal to 1 (even if `optional_member1` is unset). The expression `"optional_member2.text = 'hello'"` will also be false if `optional_member2` is unset.

To check if an optional member is set or unset, you can compare with the null keyword. The following expressions are supported:

```
"optional_member1 = null" *, *"optional_member1 <> null".
```

## 35.5.12 Sequences

Sequence elements can be accessed using the `()` or `[]` notation.

For example:

```
struct SequenceType {
    sequence<int32> s;
};
```

The following expressions are valid on a *Topic* of type `SequenceType`:

```
"s(1) = 5"
"s[1] = 5"
```

## 35.6 STRINGMATCH Filter Expression Notation

The STRINGMATCH Filter is a subset of the SQL filter; it only supports the MATCH relational operator on a single string field. It is introduced mainly for the use case of partitioning data according to channels in the *DataWriter's* [47.16 MULTI\\_CHANNEL QosPolicy \(DDS Extension\)](#) on page 830 in Market Data applications.

A STRINGMATCH filter expression has the following syntax:

```
<field name> MATCH <string pattern>
```

The STRINGMATCH filter is provided to support the narrow use case of filtering a single string field of the DDS sample against a comma-separated list of matching string values. It is intended to be used in conjunction with `ContentFilteredTopic` helper routines **`append_to_expression_parameter()`** ([35.4.3 Appending a String to an Expression Parameter on page 554](#)) and **`remove_from_expression_parameter()`** ([35.4.4 Removing a String from an Expression Parameter on page 554](#)), which allow you to easily append and remove individual string values from the comma-separated list of string values.

The STRINGMATCH filter must contain only one `<field name>`, and a single occurrence of the MATCH operator. The `<string pattern>` must be either the single parameter `%0`, or a single, comma-separated list of strings without intervening spaces.

During creation of a STRINGMATCH filter, the `<string pattern>` is automatically parameterized. That is, during creation, if the `<string pattern>` specified in the filter expression is not the parameter `%0`, then the comma-separated list of strings is copied to the initial contents of parameter 0 and the `<string pattern>` in the filter expression is replaced with the parameter `%0`.

The initial matching string list is converted to an explicit parameter value so that subsequent additions and deletions of string values to and from the list of matching strings may be performed with the

`append_to_expression_parameter()` and `remove_from_expression_parameter()` operations mentioned above.

### 35.6.1 Example STRINGMATCH Filter Expressions

This expression evaluates to TRUE if the value of `symbol` is equal to `NASDAQ/MSFT`:

```
symbol MATCH 'NASDAQ/MSFT'
```

This expression evaluates to TRUE if the value of `symbol` is equal to `NASDAQ/IBM` or `NASDAQ/MSFT`:

```
symbol MATCH 'NASDAQ/IBM,NASDAQ/MSFT'
```

This expression evaluates to TRUE if the value of `symbol` is equal to `NASDAQ` and starts with a letter between M and Y:

```
symbol MATCH 'NASDAQ/[M-Y]*'
```

```
symbol MATCH 'NASDAQ/MSFT'
```

### 35.6.2 STRINGMATCH Filter Expression Parameters

In the builtin STRINGMATCH filter, there is one, and only one, parameter: parameter 0. (If you want to add more parameters, see [35.4.3 Appending a String to an Expression Parameter on page 554](#).) The parameter can be specified explicitly using the same syntax as the SQL filter or implicitly by using a constant string pattern. For example:

```
symbol MATCH %0 (Explicit parameter)
symbol MATCH 'IBM' (Implicit parameter initialized to IBM)
```

Strings used as parameter values must contain the enclosing quotation marks (') within the parameter value; do not place the quotation marks within the expression statement. For example, the expression "symbol MATCH %0 " with parameter 0 set to " 'IBM' " is legal, whereas the expression "symbol MATCH '%0' " with parameter 0 set to " IBM " will not compile.

## 35.7 Character Encoding

*Connex* offers ISO 8859-1 as an alternative encoding for IDL strings. The default is UTF-8. To configure ISO 8859-1 for filtering of IDL strings, set the value of the *DomainParticipant's* Property Qos property `dds.domain_participant.filtering_character_encoding` to ISO-8859-1.

The possible values for `dds.domain_participant.filtering_character_encoding` are:

- UTF-8 (default value)
- ISO-8859-1

This property is applicable to the following filtering features:

- [ContentFilteredTopics](#) (see [18.3 ContentFilteredTopics on page 256](#))
- Query conditions (see [15.9.7 ReadConditions and QueryConditions on page 66](#))
- [TopicQueries](#) (see [Chapter 60 Topic Queries on page 1142](#))
- *MultiChannel DataWriters* (see [Chapter 36 Multi-Channel DataWriters for High-Performance Filtering on page 576](#))

## 35.8 Unicode Normalization

Unicode supports multiple ways to encode some characters, most notably accented characters. A composed character in Unicode can often have a number of different ways of representing the character. For example:

Precomposed  $\text{L}_x$  is represented by `\u1e3c`

Composed  $\text{L}_x = \text{L} + \text{^}$  is represented by `\u004c + \u032d`

The lexical comparison of the two characters above will return false. To do the correct comparison, the characters need to be normalized—that is, reduced to the same character composition.

When the character encoding for filtering of IDL strings is UTF-8, the Unicode normalization behavior can be controlled using a *DomainParticipant* Property Qos property called **dds.domain\_participant.filtering\_unicode\_normalization**.

The possible values of the normalization property are:

- OFF: Disables normalization
- NFD: Canonical Decomposition
- NFC (default value): Canonical Decomposition, followed by Canonical Composition
- NFKC: Compatibility Decomposition, followed by Canonical Composition
- NFKC\_Casfold: Casfold followed by NFKC normalization

This property is applicable to the following filtering features:

- [ContentFilteredTopics](#) (see [18.3 ContentFilteredTopics on page 256](#))
- Query conditions (see [15.9.7 ReadConditions and QueryConditions on page 66](#))
- [TopicQueries](#) (see [Chapter 60 Topic Queries on page 1142](#))
- *MultiChannel DataWriters* (see [Chapter 36 Multi-Channel DataWriters for High-Performance Filtering on page 576](#))

Because normalization may affect performance, and it is enabled by default, the property allows disabling the normalization process per *DomainParticipant* using the value OFF. However, be aware that doing this may lead to unexpected behavior.

## 35.9 Custom Content Filters

By default, a `ContentFilteredTopic` will use a SQL-like content filter, `DDS_SQLFILTER_NAME` (see [35.5 SQL Filter Expression Notation on page 555](#)), which implements a superset of the content filter. There is another builtin filter, `DDS_STRINGMATCHFILTER_NAME` (see [35.6 STRINGMATCH Filter Expression Notation on page 564](#)). Both of these are automatically registered.

If you want to use a different filter, **you must register it first**, then create the `ContentFilteredTopic` using `create_contentfilteredtopic_with_filter()` (see [35.2 Creating ContentFilteredTopics on page 548](#)).

One reason to use a custom filter is that the default filter can only filter based on relational operations between topic members, not on a computation involving topic members. For example, if you want to filter based on the sum of the members, you must create your own filter.

### Note:

- The API for using a custom content filter is subject to change in a future release.

### 35.9.1 Filtering on the Writer Side with Custom Filters

There are two approaches for performing writer-side filtering. The first approach is to evaluate each written DDS sample against filters of all the readers that have content filter specified and identify the readers whose filter passes the DDS sample.

The second approach is to evaluate the written DDS sample once for the writer and then rely on the filter implementation to provide a set of readers whose filter passes the DDS sample. This approach allows the filter implementation to cache the result of filtering, if possible. For example, consider a scenario where the data is described by the struct shown below, where  $10 < x < 20$ :

```
struct MyData {
    int x;
    int y;
};
```

If the filter expression is based only on the `x` field, the filter implementation can maintain a hash map for all the different values of `x` and cache the filtering results in the hash map. Then any future evaluations will only be  $O(1)$ , because it only requires a lookup in the hash map.

But if in the same example, a reader has a content filter that is based on both `x` and `y`, or just `y`, the filter implementation cannot cache the result—because the filter was only maintaining a hash map for `x`. In this case, the filter implementation can inform *Connex* that it will not be caching the result for those *DataReaders*. The filter can use `DDS_ExpressionProperty` to indicate to the middleware whether or not

it will cache the results for *DataReader*. Table 35.4 *DDS\_ExpressionProperty* describes *DDS\_ExpressionProperty*.

**Table 35.4 DDS\_ExpressionProperty**

Type	Field Name	Description
DDS_Boolean	key_only_filter	Indicates if the filter expression is based only on key fields. In this case, <i>Connex</i> itself can cache the filtering results.
DDS_Boolean	writer_side_filter_optimization	Indicates if the filter implementation can cache the filtering result for the expression provided. If this is true then <i>Connex</i> will do no caching or explicit filter evaluation for the associated <i>DataReader</i> . It will instead rely on the filter implementation to provide appropriate results.

## 35.9.2 Registering a Custom Filter

To use a custom filter, it must be registered in the following places:

- Register the custom filter in any subscribing application in which the filter is used to create a *ContentFilteredTopic* and corresponding *DataReader*.
- In each publishing application, you only need to register the custom filter if you want to perform writer-side filtering. A *DataWriter* created with an associated filter will use that filter if it discovers a matched *DataReader* that uses the same filter.

For example, suppose Application A on the subscription side creates a *Topic* named **X** and a *ContentFilteredTopic* named **filteredX** (and a corresponding *DataReader*), using a previously registered content filter, **myFilter**. With only that, you will have filtering on the subscription side. If you also want to perform filtering in any application that publishes *Topic X*, then you also need to register the same definition of the *ContentFilter myFilter* in that application.

To register a new filter, use the *DomainParticipant's register\_contentfilter()* operation<sup>1</sup>:

```
DDS_ReturnCode_t register_contentfilter(
    const char * filter_name,
    const DDSContentFilter * contentfilter)
```

- **filter\_name**

The name of the filter. The name must be unique within the *DomainParticipant*. The **filter\_name** cannot have a length of 0. The same filtering functions and handle can be registered under different names.

<sup>1</sup>This operation is an extension to the DDS standard.

- **content\_filter**

This class specifies the functions that will be used to process the filter.

You must derive from the `DDSContentFilter` base class and implement the virtual [compile below](#), [evaluate below](#), and [finalize below](#) functions described below.

Optionally, you can derive from the `DDSWriterContentFilter` base class instead, to implement additional filtering operations that will be used by the *DataWriter*. When performing writer-side filtering, these operations allow a DDS sample to be evaluated once for the *DataWriter*, instead of evaluating the DDS sample for every *DataReader* that is matched with the *DataWriter*. An instance of the derived class is then used as an argument when calling `register_contentfilter()`.

- **compile**

The function that will be used to compile a filter expression and parameters. *Connex* will call this function when a `ContentFilteredTopic` is created and when the filter parameters are changed. This parameter cannot be NULL. See [35.9.5 Compile Function on page 571](#). This is a member of `DDSContentFilter` and `DDSWriterContentFilter`.

- **evaluate**

The function that will be called by *Connex* each time a DDS sample is received. Its purpose is to evaluate the DDS sample based on the filter. This parameter cannot be NULL. See [35.9.6 Evaluate Function on page 572](#). This is a member of `DDSContentFilter` and `DDSWriterContentFilter`.

- **finalize**

The function that will be called by *Connex* when an instance of the custom content filter is no longer needed. This parameter may be NULL. See [35.9.7 Finalize Function on page 572](#). This is a member of `DDSContentFilter` and `DDSWriterContentFilter`.

- **writer\_attach**

The function that will be used to create some state required to perform filtering on the writer side using the operations provided in `DDSWriterContentFilter`. *Connex* will call this function for every *DataWriter*; it will be called only the *first time* the *DataWriter* matches a *DataReader* using the specified filter. This function will not be called for any subsequent *DataReaders* that match the *DataWriter* and are using the same filter. See [35.9.8 Writer Attach Function on page 573](#). This is a member of `DDSWriterContentFilter`.

- **writer\_detach**

The function that will be used to delete any state created using the `writer_attach` function. *Connex* will call this function when the *DataWriter* is deleted. See [35.9.9 Writer Detach Function on page 573](#). This is a member of `DDSWriterContentFilter`.

- **writer\_compile**

The function that will be used by the *DataWriter* to compile filter expression and parameters provided by the reader. *Connex* will call this function when the *DataWriter* discovers a *DataReader* with a *ContentFilteredTopic* or when a *DataWriter* is notified of a change in *DataReader*'s filter parameter. This function will receive as an input a **DDS\_Cookie\_t** which uniquely identifies the *DataReader* for which the function was invoked. See [35.9.10 Writer Compile Function on page 573](#). This is a member of *DDSWriterContentFilter*.

- **writer\_evaluate**

The function that will be called by *Connex* every time a *DataWriter* writes a new DDS sample. Its purpose is to evaluate the DDS sample for all the readers for which the *DataWriter* is performing writer-side filtering and return the list of **DDS\_Cookie\_t** associated with the *DataReaders* whose filter pass the DDS sample. See [35.9.11 Writer Evaluate Function on page 574](#).

- **writer\_return\_loan**

The function that will be called by *Connex* to return the loan on a sequence of **DDS\_Cookie\_t** provided by the **writer\_evaluate** function. See [35.9.12 Writer Return Loan Function on page 574](#). This is a member of *DDSWriterContentFilter*.

- **writer\_finalize**

The function that will be called by *Connex* to notify the filter implementation that the *DataWriter* is no longer matching with a *DataReader* for which it was previously performing writer-side filtering. This will allow the filter to purge any state it was maintaining for the *DataReader*. See [35.9.13 Writer Finalize Function on page 575](#). This is a member of *DDSWriterContentFilter*.

### 35.9.3 Unregistering a Custom Filter

To unregister a filter, use the *DomainParticipant*'s **unregister\_contentfilter()** operation<sup>1</sup>, which is useful if you want to reuse a particular filter name. (Note: You do not have to unregister the filter before deleting the parent *DomainParticipant*. If you do not need to reuse the filter name to register another filter, there is no reason to unregister the filter.)

```
DDS_ReturnCode_t unregister_contentfilter(const char * filter_name)
```

**filter\_name**      The name of the previously registered filter. The name must be unique within the *DomainParticipant*. The **filter\_name** cannot have a length of 0.

If you attempt to unregister a filter that is still being used by a *ContentFilteredTopic*, **unregister\_contentfilter()** will return **PRECONDITION\_NOT\_MET**.

<sup>1</sup>This operation is an extension to the DDS standard.

If there are still existing discovered *DataReaders* with the same **filter\_name** and the filter's **compile** function has previously been called on the discovered *DataReaders*, the filter's **finalize** function will be called on those discovered *DataReaders* before the content filter is unregistered. This means filtering will be performed on the application that is creating the *DataReader*.

## 35.9.4 Retrieving a ContentFilter

If you know the name of a ContentFilter, you can get a pointer to its structure. If the ContentFilter has not already been registered, this operation will return NULL.

```
DDS_ContentFilter *lookup_contentfilter (const char * filter_name)
```

## 35.9.5 Compile Function

The **compile** function specified in the ContentFilter will be used to compile a filter expression and parameters. Please note that the term 'compile' is intentionally defined very broadly. It is entirely up to you, as the user, to decide what this function should do. The only requirement is that the **error\_code** parameter passed to the compile function must return **OK** on successful execution. For example:

```
DDS_ReturnCode_t sample_compile_function(
    void ** new_compile_data, const char * expression,
    const DDS_StringSeq & parameters,
    const DDS_TypeCode * type_code,
    const char * type_class_name,
    void * old_compile_data)
{
    *new_compile_data = (void*)DDS_String_dup(parameters[0]);
    return DDS_RETCODE_OK;
}
```

Where:

<b>new_compile_data</b>	A user-specified opaque pointer of this instance of the content filter. This value is passed to the <b>evaluate</b> and <b>finalize</b> functions
<b>expression</b>	An ASCII string with the filter expression the ContentFilteredTopic was created with. Note that the memory used by the parameter pointer is owned by <i>Connex</i> . If you want to manipulate this string, you <i>must</i> make a copy of it first. Do not free the memory for this string.
<b>parameters</b>	A string sequence of expression parameters used to create the ContentFilteredTopic. The string sequence is equal (but not identical) to the string sequence passed to <b>create_contentfilteredtopic()</b> (see <b>expression_parameters</b> in <a href="#">35.2 Creating ContentFilteredTopics on page 548</a> ).  The sequence passed to the <b>compile</b> function is owned by <i>Connex</i> and must not be referred to outside the <b>compile</b> function.
<b>type_code</b>	A pointer to the type code of the related <i>Topic</i> . A type code is a description of the topic members, such as their type (long, octet, etc.), but does not contain any information with respect to the memory layout of the structures. The type code can be used to write filters that can be used with any type. See <a href="#">17.7 Using Generated Types without Connex (Standalone) on page 234</a> . [Note: If you are using the Java API, this parameter will always be NULL.]

<b>type_class_name</b>	Fully qualified class name of the related <i>Topic</i> .
<b>old_compile_data</b>	The <b>new_compile_data</b> value from a <i>previous</i> call to this instance of a content filter. If <b>compile</b> is called more than once for an instance of a ContentFilteredTopic (such as if the expression parameters are changed), then the <b>new_compile_data</b> value returned by the previous invocation is passed in the <b>old_compile_data</b> parameter (which can be NULL). If this is a new instance of the filter, NULL is passed. This parameter is useful for freeing or reusing previously allocated resources.

## 35.9.6 Evaluate Function

The **evaluate** function specified in the ContentFilter will be called each time a DDS sample is received. This function's purpose is to determine if a DDS sample should be filtered out (not put in the receive queue).

For example:

```
DDS_Boolean sample_evaluate_function(
    void* compile_data,
    const void* sample,
    struct DDS_FilterSampleInfo * meta_data) {
    char *parameter = (char*)compile_data;
    DDS_Long x;
    Foo *foo_sample = (Foo*)sample;
    sscanf(parameter, "%d", &x);
    return (foo_sample->x > x ? DDS_BOOLEAN_FALSE : DDS_BOOLEAN_TRUE);
}
```

The function may use the following parameters:

<b>compile_data</b>	The last return value from the <b>compile</b> function for this instance of the content filter. Can be NULL.
<b>sample</b>	A pointer to a C structure with the data to filter. Note that the <b>evaluate</b> function always receives <i>deserialized</i> data.
<b>meta_data</b>	A pointer to the meta data associated with the DDS sample.

**Note:** Currently the **meta\_data** field only supports **related\_sample\_identity** (described in [Table 31.15 DDS\\_WriteParams\\_t](#)).

## 35.9.7 Finalize Function

The **finalize** function specified in the ContentFilter will be called when an instance of the custom content filter is no longer needed. When this function is called, it is safe to free all resources used by this particular instance of the custom content filter.

For example:

```
void sample_finalize_function ( void* compile_data) {
    /* free parameter string from compile function */
    DDS_String_free((char *)compile_data);
}
```

The **finalize** function may use the following optional parameters:

<b>system_key</b>	See <a href="#">35.9.5 Compile Function on page 571</a> .
<b>handle</b>	This is the handle returned by the last call to the <b>compile</b> function.

## 35.9.8 Writer Attach Function

The **writer\_attach** function specified in the `WriterContentFilter` will be used to create some state that can be used by the filter to perform writer-side filtering more efficiently. It is entirely up to you, as the implementer of the filter, to decide if the filter requires this state.

The function has the following parameter:

<b>writer_filter_data</b>	A user-specified opaque pointer to some state created on the writer side that will help perform writer-side filtering efficiently.
---------------------------	------------------------------------------------------------------------------------------------------------------------------------

## 35.9.9 Writer Detach Function

The **writer\_detach** function specified in the `WriterContentFilter` will be used to free up any state that was created using the **writer\_attach** function.

The function has the following parameter:

<b>writer_filter_data</b>	A pointer to the state created using the <b>writer_attach</b> function.
---------------------------	-------------------------------------------------------------------------

## 35.9.10 Writer Compile Function

The **writer\_compile** function specified in the `WriterContentFilter` will be used by a *DataWriter* to compile a filter expression and parameters associated with a *DataReader* for which the *DataWriter* is performing filtering. The function will receive as input a **DDS\_Cookie\_t** that uniquely identifies the *DataReader* for which the function was invoked.

The function has the following parameters:

<b>writer_filter_data</b>	A pointer to the state created using the <b>writer_attach</b> function.
<b>prop</b>	A pointer to <code>DDS_ExpressionProperty</code> . This is an output parameter. It allows you to indicate to <i>Connex</i> if a filter expression can be optimized (as described in <a href="#">35.9.1 Filtering on the Writer Side with Custom Filters on page 567</a> ).

<b>expression</b>	An ASCIIZ string with the filter expression the ContentFilteredTopic was created with. Note that the memory used by the parameter pointer is owned by <i>Connex</i> . If you want to manipulate this string, you must make a copy of it first. Do not free the memory for this string.
<b>parameters</b>	A string sequence of expression parameters used to create the ContentFilteredTopic. The string sequence is equal (but not identical) to the string sequence passed to <b>create_contentfilteredtopic()</b> (see <b>expression_parameters</b> in <a href="#">35.2 Creating ContentFilteredTopics on page 548</a> ).  The sequence passed to the <b>compile</b> function is owned by <i>Connex</i> and must not be referred to outside the <b>writer_compile</b> function.
<b>type_code</b>	A pointer to the type code of the related Topic. A type code is a description of the topic members, such as their type (long, octet, etc.), but does not contain any information with respect to the memory layout of the structures. The type code can be used to write filters that can be used with any type. See <a href="#">17.7 Using Generated Types without Connex (Standalone) on page 234</a> . [Note: If you are using the Java API, this parameter will always be NULL.]
<b>type_class_name</b>	The fully qualified class name of the related Topic.
<b>cookie</b>	A <b>DDS_Cookie_t</b> to uniquely identify the <i>DataReader</i> for which the <b>writer_compile</b> function was called.

### 35.9.11 Writer Evaluate Function

The **writer\_evaluate** function specified in the *WriterContentFilter* will be used by a *DataWriter* to retrieve the list of *DataReaders* whose filter passed the DDS sample. The **writer\_evaluate** function returns a sequence of cookies which identifies the set of *DataReaders* whose filter passes the DDS sample.

The function has the following parameters:

<b>writer_filter_data</b>	A pointer to the state created using the <b>writer_attach</b> function.
<b>sample</b>	A pointer to the data to be filtered. Note that the <b>writer_evaluate</b> function always receives <i>deserialized</i> data.
<b>meta_data</b>	A pointer to the meta-data associated with the DDS sample.

**Note:** Currently the **meta\_data** field only supports **related\_sample\_identity** (described in [Table 31.15 DDS\\_WriteParams\\_t](#)).

### 35.9.12 Writer Return Loan Function

*Connex* uses the **writer\_return\_loan** function specified in the *WriterContentFilter* to indicate to the filter implementation that it has finished using the sequence of cookies returned by the filter's **writer\_evaluate** function. Your filter implementation should *not* free the memory associated with the cookie sequence before the **writer\_return\_loan** function is called.

The function has the following parameters:

<b>writer_filter_data</b>	A pointer to the state created using the <b>writer_attach</b> function.
---------------------------	-------------------------------------------------------------------------

**cookies**                      The sequence of cookies for which the **writer\_return\_loan** function was called.

### 35.9.13 Writer Finalize Function

The **writer\_finalize** function specified in the `WriterContentFilter` will be called when the *DataWriter* no longer matches with a *DataReader* that was created with `ContentFilteredTopic`. This will allow the filter implementation to delete any state it was maintaining for the *DataReader*.

The function has the following parameters:

**writer\_filter\_data**            A pointer to the state created using the **writer\_attach** function.

**cookie**                         A `DDS_Cookie_t` to uniquely identify the *DataReader* for which the `writer_finalize` was called.

# Chapter 36 Multi-Channel DataWriters for High-Performance Filtering

In *Connex*, producers publish data to a *Topic*, identified by a topic name; consumers subscribe to a *Topic* and optionally to specific content by means of a content-filter expression.

A Market Data Example:

A producer can publish data on the Topic "MarketData" which can be defined as a structured record containing fields that identify the exchange (e.g., "NYSE" or "NASDAQ"), the stock symbol (e.g., "APPL" or "JPM"), volume, bid and ask prices, etc.

Similarly, a consumer may want to subscribe to data on the "MarketData" Topic, but only if the exchange is "NYSE" or the symbol starts with the letter "M." Or the consumer may want all the data from the "NYSE" whose volume exceeds a certain threshold, or may want MarketData for a specific stock symbol, regardless of the exchange, and so on.

The middleware's efficient implementation of content-filtering is critical for scenarios such as the above "Market Data" example, where there are large numbers of consumers, large volumes of data, or Topics that transmit information about many data-objects or subjects (e.g., individual stocks).

Traditionally, middleware products use four approaches to implement content filtering: Producer-based, Consumer-based, Server-based, and Network Switch-based.

- **Producer-based approaches** push the burden of filtering to the producer side. The producer knows what each consumer wants and delivers to the consumer only the data that matches the consumer's filter. This approach is suitable when using point-to-point protocols such as TCP—it saves bandwidth and lowers the load on the consumer—but it does not work if data is distributed via multicast. Also, this approach does not scale to large numbers of consumers, because the producer would be overburdened by the need to

filter for each individual consumer.

- **Consumer-based approaches** push the burden of filtering to the consumer side. The producer sends all the data to every consumer and the middleware on the consumer side decides whether the application wants it or not, automatically filtering the unwanted data. This approach is simple and fits well in systems that use multicast protocols as a transport. But the approach is not efficient for consumers that want small subsets of the data, since the consumers have to spend a lot of time filtering unwanted data. This approach is also unsuitable for systems with large volumes of data, such as the above Market Data system.
- **Server-based approaches** push the burden of filtering to a third component: a server or broker. This approach has some scalability advantages—the server can be run on a more powerful computer and can be federated to handle a large number of consumers. Some providers also provide hardware-assisted filtering in the server. However, the server-based approach significantly increases latency and jitter. It is also far more expensive to deploy and manage.
- **Network Switch-based approaches** leverage the network hardware, specifically advanced (IGMP snooping) network switches, to offload most of the burden of filtering from the producers and consumers without introducing additional hardware, servers or proxies. This approach preserves the low latency and ease of deployment of the brokerless approaches while still providing most of the off-loading and scalability benefits of the broker.

RTI supports the producer-based, consumer-based and network-switch approaches to content filtering:

- RTI automatically uses the producer-based and consumer-based approaches as soon as it detects a consumer that specifies a content filter. The producer-based (publishing side) approach only occurs under the conditions described in [35.1 Where Filtering is Applied—Publishing vs. Subscribing Side on page 547](#).
- To use the more scalable network-switched based approach, an application must configure the *DataWriter* as a *Multi-channel DataWriter*. This concept is described in the following section.

## 36.1 Overview of Multi-Channel DataWriters

A *Multi-channel DataWriter* is a *DataWriter* that is configured to send data over multiple multicast addresses, according to some filtering criteria applied to the data.

To determine which multicast addresses will be used to send the data, the middleware evaluates a set of filters that are configured for the *DataWriter*. Each filter "guards" a *channel*—a set of multicast addresses. Each time a multi-channel *DataWriter* writes data, the filters are applied. If a filter evaluates to true, the data is sent over that filter's associated channel (set of multicast addresses). We refer to this type of filter as a *Channel Guard filter*.

Figure 36.1: Multi-channel Data Flow

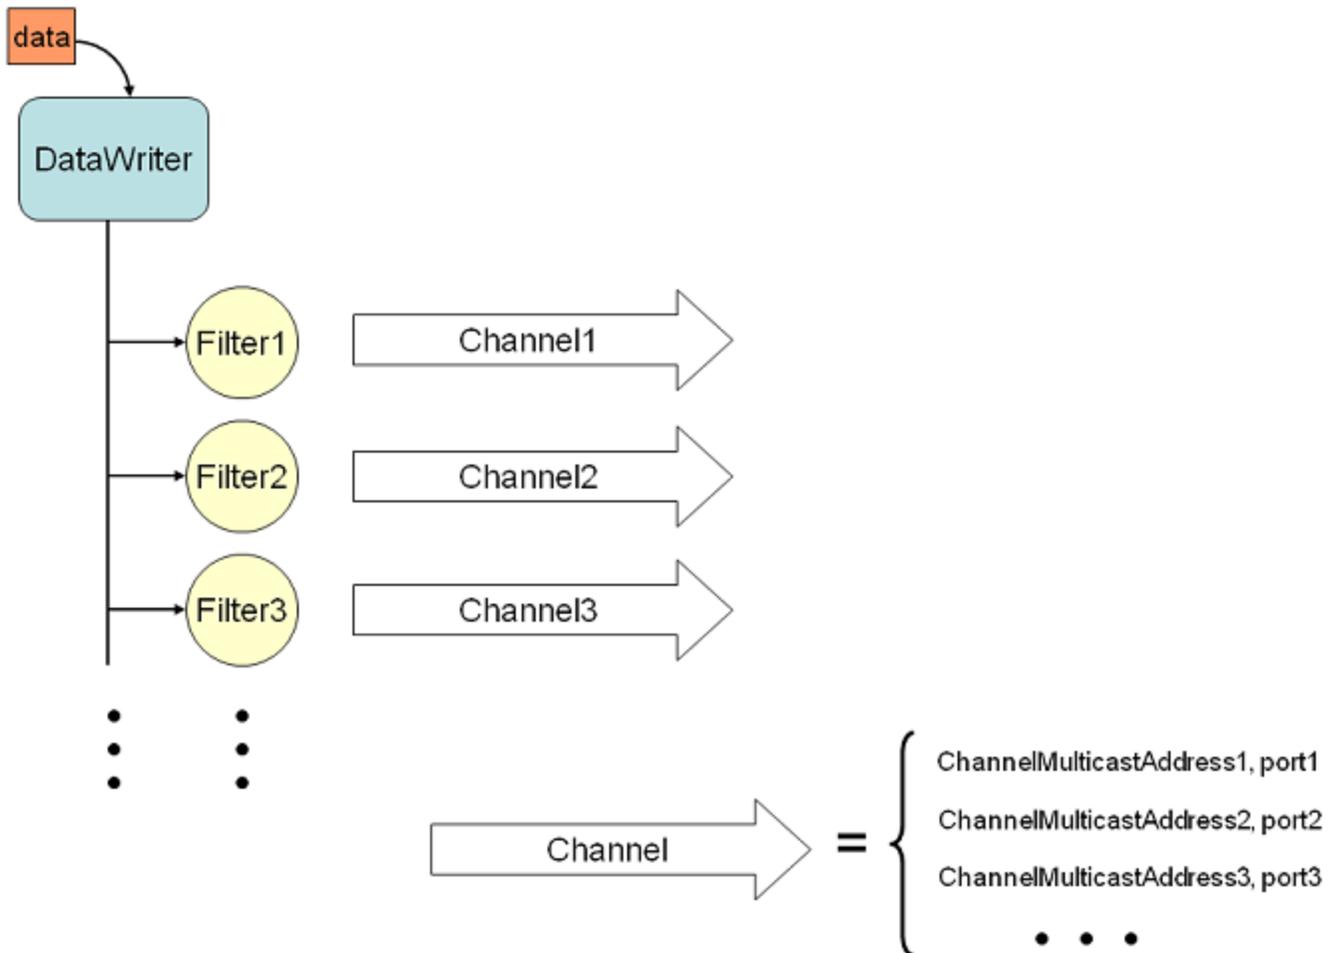

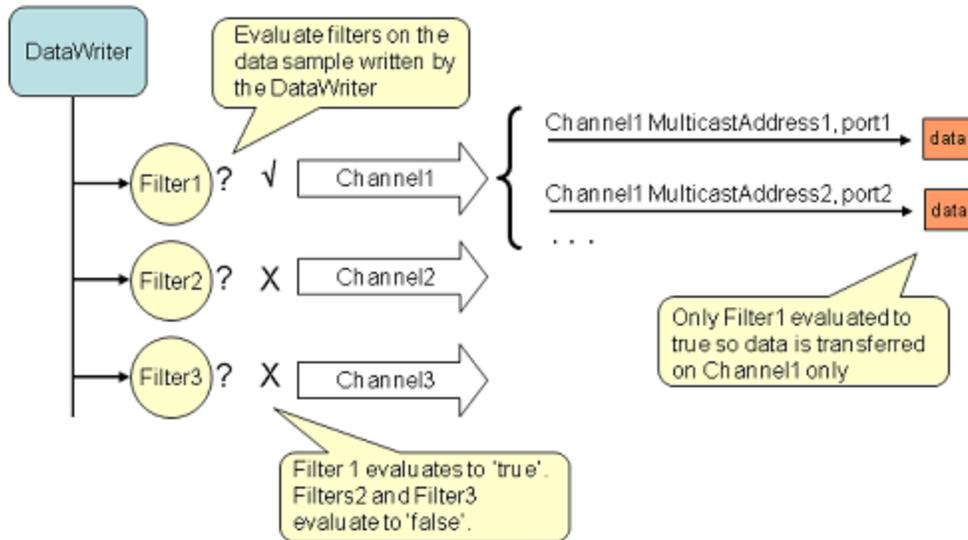

Figure 36.2: Multi-Channel Evaluation

Multi-channel *DataWriters* can be used to trade off network bandwidth with the unnecessary processing of unwanted data for situations where there are multiple *DataReaders* who are interested in different subsets of data that come from the same data stream (Topic). For example, in Financial applications, the data stream may be quotes for different stocks at an exchange. Applications usually only want to receive data (quotes) for only a subset of the stocks being traded. In tracking applications, a data stream may carry information on hundreds or thousands of objects being tracked, but again, applications may only be interested in a subset.

The problem is that the most efficient way to deliver data to multiple applications is to use multicast so that a data value is only sent once on the network for any number of subscribers to the data. However, using multicast, an application will receive all of the data sent and not just the data in which it is interested, thus extra CPU time is wasted to throw away unwanted data. With this QoS, you can analyze the data-usage patterns of your applications and optimize network vs. CPU usage by partitioning the data into multiple multicast streams. While network bandwidth is still being conserved by sending data only once using multicast, most applications will only need to listen to a subset of the multicast addresses and receive a reduced amount of unwanted data.

**Note:** Your system can gain more of the benefits of using multiple multicast groups if your network uses Layer 2 Ethernet switches. Layer 2 switches can be configured to only route multicast packets to those ports that have added membership to specific multicast groups. Using those switches will ensure that only the multicast packets used by applications on a node are routed to the node; all others are filtered-out by the switch.

## 36.2 How to Configure a Multi-Channel DataWriter

To configure a multi-channel *DataWriter*, simply define a list of all its *channels* in the *DataWriter*'s [47.16 MULTI\\_CHANNEL QosPolicy \(DDS Extension\)](#) on page 830.

Each *channel* consists of filter criterion to apply to the data and a set of multicast destinations (transport, address, port) that will be used for sending data that matches the filter. You can think of this sequence of channels as a table like the one shown below:

If the Data Matches this Filter...	Send the Data to these Multicast Destinations
Symbol MATCH '[A-K]*'	UDPv4:225.0.0.1:9000
Symbol MATCH '[L-Q]*'	UDPv4:225.0.0.2:9001
Symbol MATCH '[P-Z]*'	UDPv4:225.0.0.3:9002; 225.0.0.4:9003;

The example C++ code in [Figure 36.3: Using the MULTI\\_CHANNEL QosPolicy](#) below shows how to configure the channels.

**Figure 36.3: Using the MULTI\_CHANNEL QosPolicy**

```
// initialize writer_qos with default values
publisher->get_default_datawriter_qos(writer_qos);
// Initialize MULTI_CHANNEL Qos Policy
// Assign the filter name
// Possible options: DDS_STRINGMATCHFILTER_NAME, DDS_SQLFILTER_NAME
writer_qos.multi_channel.filter_name =
    (char*) DDS_STRINGMATCHFILTER_NAME;
// Create two channels
writer_qos.multi_channel.channels.ensure_length(2,2);
// First channel
writer_qos.multi_channel.channels[0].filter_expression =
    DDS_String_dup("Symbol MATCH '[A-M]*'");
writer_qos.multi_channel.channels[0].
    multicast_settings.ensure_length(1,1);
writer_qos.multi_channel.channels[0].
    multicast_settings[0].receive_port = 8700;
writer_qos.multi_channel.channels[0].
    multicast_settings[0].receive_address =
    DDS_String_dup("239.255.1.1");
// Second channel
writer_qos.multi_channel.channels[1].
    multicast_settings.ensure_length(1,1);
writer_qos.multi_channel.channels[1].
    multicast_settings[0].receive_port = 8800;
writer_qos.multi_channel.channels[1].
    multicast_settings[0].receive_address =
    DDS_String_dup("239.255.1.2");
writer_qos.multi_channel.channels[1].filter_expression =
    DDS_String_dup("Symbol MATCH '[N-Z]*'");
// Create writer
```

```
writer = publisher->create_datawriter(
    topic, writer_qos, NULL, DDS_STATUS_MASK_NONE);
```

The MULTI\_CHANNEL QoSPolicy is propagated along with discovery traffic. The value of this policy is available in the builtin topic for the publication (see the **locator\_filter** field in [Table 28.2 Publication Built-in Topic's Data Type \(DDS\\_PublicationBuiltinTopicData\)](#)).

## 36.2.1 Limitations

When considering use of a multi-channel DataWriter, please be aware of the following limitations:

- A *DataWriter* that uses the MULTI\_CHANNEL QoSPolicy will ignore multicast and unicast addresses specified on the reader side through the [48.5 TRANSPORT\\_MULTICAST QoSPolicy \(DDS Extension\) on page 891](#) and [47.28 TRANSPORT\\_UNICAST QoSPolicy \(DDS Extension\) on page 859](#). The *DataWriter* will not publish DDS samples on these locators.
- Multi-channel *DataWriters* cannot be configured to use the Durable Writer History feature (described in [21.3 Durable Writer History on page 295](#)).
- Multi-channel *DataWriters* rely on the **rtps\_object\_id** in the [47.5 DATA\\_WRITER\\_PROTOCOL QoSPolicy \(DDS Extension\) on page 788](#) to be DDS\_RTPS\_AUTO\_ID (which causes automatic assignment of object IDs to channels).
- To guarantee reliable delivery, a *DataReader's* [46.6 PRESENTATION QoSPolicy on page 760](#) must be set to per-instance ordering (DDS\_INSTANCE\_PRESENTATION\_QOS, the default value), instead of per-topic ordering (DDS\_TOPIC\_PRESENTATION\_QOS), and the matching *DataWriter's* [47.16 MULTI\\_CHANNEL QoSPolicy \(DDS Extension\) on page 830](#) must use expressions that only refer to key fields.

## 36.3 Multi-Channel Configuration on the Reader Side

*No special changes are required in a subscribing application to get data from a multi-channel DataWriter.*

If you want the *DataReader* to subscribe to only a subset of the channels, use a ContentFilteredTopic, as described in [18.3 ContentFilteredTopics on page 256](#). For example:

```
// Create a content filtered topic
contentFilter =
    participant->create_contentfilteredtopic_with_filter(
        "FilteredTopic",
        topic,
        "symbol MATCH 'NYSE/BAC,NASDAQ/MSFT,NASDAQ/GOOG'",
        parameters,
        DDS_STRINGMATCHFILTER_NAME);
// Create a DataReader that uses the content filtered topic
reader = subscriber->create_datareader(contentFilter,
    DDS_DATAREADER_QOS_DEFAULT,
    NULL, 0);
```

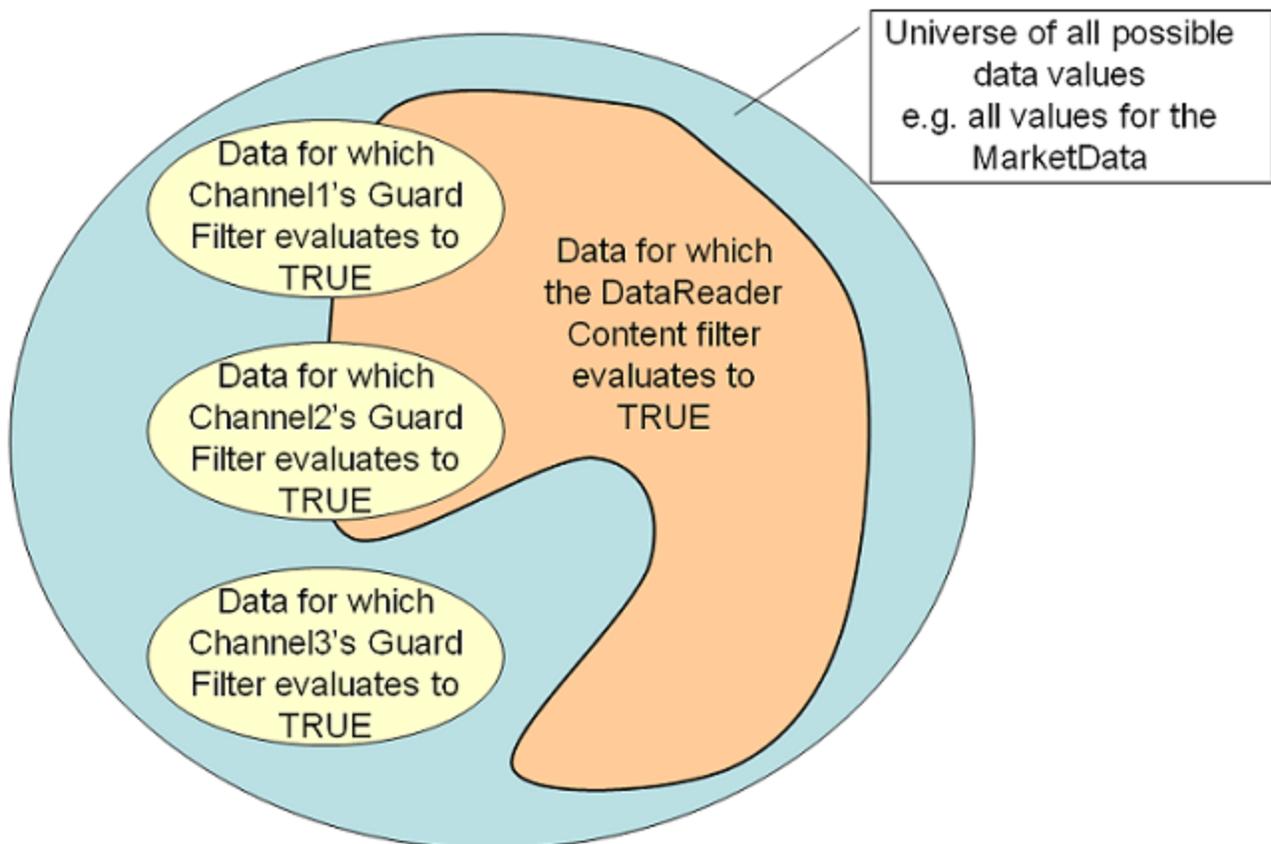

From there, *Connex* takes care of all the necessary steps:

- The *DataReader* automatically discovers all the *DataWriters*—including multi-channel *DataWriters*—for the Topic it subscribes to.
- When the *DataReader* discovers a multi-channel *DataWriter*, it also discovers the list of channels used by that *DataWriter*.
- When the multi-channel *DataWriter* discovers a *DataReader*, it also discovers the content filters specified by that *DataReader*, if any.

With all this information, *Connex* automatically determines which channels are of "interest" to the *DataReader*.

A *DataReader* is interested in a channel if and only if the set of data values for which the channel guard filter evaluates to TRUE intersects the set of data values for which the *DataReader's* content filter evaluates to TRUE. If a *DataReader* does not use a content filter, then it is interested in all the channels.

Figure 36.4: Filter Intersection

*In this scenario, the DataReader is interested in Channel1 and Channel2, but not Channel3.*

### Market Data Example, continued:

If the channel guard filter for Channel 1 is 'Symbol MATCH '[A-K]\*' then the channel will only transfer data for stocks whose symbol starts with a letter in the A to K range.

That is, it will transfer data on 'APPL', 'GOOG', and 'IBM', but not on 'MSFT', 'ORCL', or 'YHOO'. Channel 1 will be of interest to *DataReaders* whose content filter includes at least one stock whose symbol starts with a letter in the A to K range.

A *DataReader* that specifies a content filter such as "Symbol MATCH 'IBM, YHOO' " will be interested in Channel1.

A *DataReader* that specifies a content filter such as "Symbol MATCH '[G-M]\*'" will also be interested in Channel1.

A *DataReader* that specifies a content filter such as "Symbol MATCH '[M-T]\*' " will not be interested in Channel1.

## 36.4 Where Does the Filtering Occur?

If multi-channel *DataWriters* are used, the filtering can occur in three places:

- [36.4.1 Filtering at the DataWriter below](#)
- [36.4.2 Filtering at the DataReader below](#)
- [36.4.3 Filtering on the Network Hardware on the next page](#)

### 36.4.1 Filtering at the DataWriter

Each time data is written, the *DataWriter* evaluates each of the channel guard filters to determine which channels will transmit the data. This filtering occurs on the *DataWriter*.

Filtering on the *DataWriter* side is scalable because the number of filter evaluations depends only on the number of channels, not on the number of *DataReaders*. Usually, the number of channels is smaller than the number of possible *DataReaders*.

As explained in [36.7 Performance Considerations on page 586](#), if the channel guard filters are configured to only look at the "key" fields in the data, the channel filtering becomes a very efficient lookup operation.

### 36.4.2 Filtering at the DataReader

The *DataReader* will listen on the multicast addresses that correspond to the channels of interest (see [Figure 36.3: Using the MULTI\\_CHANNEL QosPolicy on page 580](#)). When a channel is 'of interest', it means that it is possible for the channel to transmit data that meets the content filter of the *DataReader*,

however the channel may also transmit data that does not pass the *DataReader's* content filter. Therefore, the *DataReader* has to filter all incoming data on that channel to determine if it passes its content filter.

### Market Data Example, continued:

Channel 1, identified by guard filter "Symbol MATCH '[A-M]\*'", will be of interest to *DataReaders* whose content filter includes at least one stock whose symbol starts with a letter in the A to K range.

A *DataReader* with content filter "Symbol MATCH 'GOOG'" will listen on Channel1.

In addition to 'GOOG', the *DataReader* will also receive DDS samples corresponding to stock symbols such as 'MSFT' and 'APPL'. The *DataReader* must filter these DDS samples out.

As explained in [36.7 Performance Considerations on page 586](#), if the *DataReader's* content filters are configured to only look at the "key" fields in the data, the *DataReader* filtering becomes a very efficient lookup operation.

## 36.4.3 Filtering on the Network Hardware

*DataReaders* will only listen to multicast addresses that correspond to the channels of interest. The multicast traffic generated in other channels will be filtered out by the network hardware (routers, switches).

Layer 3 routers will only forward multicast traffic to the actual destination ports. However, by default, layer 2 switches treat multicast traffic as broadcast traffic. To take advantage of network filtering with layer 2 devices, they must be configured with IGMP snooping enabled (see [36.7.1 Network-Switch Filtering on page 586](#)).

## 36.5 Fault Tolerance and Redundancy

To achieve fault tolerance and redundancy, configure the *DataWriter's* [47.16 MULTI\\_CHANNEL QosPolicy \(DDS Extension\) on page 830](#) to publish a DDS sample over multiple channels or over different multicast addresses within a single channel. [Figure 36.5: Using the MULTI\\_CHANNEL QosPolicy with Overlapping Channels on the next page](#) shows how to use overlapping channels.

If a DDS sample is published to multiple multicast addresses, a *DataReader* may receive multiple copies of the DDS sample. By default, duplicates are discarded by the *DataReader* and not provided to the application. To change this default behavior, use the Durable Reader State property, `dds.data_reader.state.filter_redundant_samples` (see [21.4.4 How To Configure a DataReader for Durable Reader State on page 303](#)).

Figure 36.5: Using the MULTI\_CHANNEL QosPolicy with Overlapping Channels

```

// initialize writer_qos with default values
publisher->get_default_datawriter_qos(writer_qos);
// Initialize MULTI_CHANNEL Qos Policy
// Assign the filter name
// Possible options: DDS_STRINGMATCHFILTER_NAME and DDS_SQLFILTER_NAME
writer_qos.multi_channel.filter_name = (char*) DDS_STRINGMATCHFILTER_NAME;
// Create two channels
writer_qos.multi_channel.channels.ensure_length(2,2);
// First channel
writer_qos.multi_channel.channels[0].filter_expression =
    DDS_String_dup("Symbol MATCH '[A-M]*'");
writer_qos.multi_channel.channels[0].multicast_settings.ensure_length(2,2);
writer_qos.multi_channel.channels[0].multicast_settings[0].receive_port = 8700;
writer_qos.multi_channel.channels[0].multicast_settings[0].receive_address =
    DDS_String_dup("239.255.1.1");
// Second channel
writer_qos.multi_channel.channels[1].multicast_settings.ensure_length(1,1);
writer_qos.multi_channel.channels[1].multicast_settings[0].receive_port = 8800;
writer_qos.multi_channel.channels[1].multicast_settings[0].receive_address =
    DDS_String_dup("239.255.1.2");
writer_qos.multi_channel.channels[1].filter_expression =
    DDS_String_dup("Symbol MATCH '[C-Z]*'");
// Symbols starting with [C-M] will be published in two different channels
// Create writer
writer = publisher->create_datawriter(
    topic, writer_qos, NULL, DDS_STATUS_MASK_NONE);

```

## 36.6 Reliability with Multi-Channel DataWriters

### 36.6.1 Reliable Delivery

Reliable delivery is only guaranteed when the **access\_scope** in the *Subscriber's* [46.6 PRESENTATION QosPolicy on page 760](#) is set to `DDS_INSTANCE_PRESENTATION_QOS` (default value) and the filters in the *DataWriter's* [47.16 MULTI\\_CHANNEL QosPolicy \(DDS Extension\) on page 830](#) are keyed-only based.

Market Data Example, continued:

Given the following IDL description for our MarketData topic type:

```

Struct MarketData {
    @key string<255> Symbol;
    double Price;
}

```

A guard filter "Symbol MATCH 'APPL'" is keyed-only based.

A guard filter "Symbol MATCH 'APPL' and Price < 100" is not keyed-only based.

If any of the guard filters are based on non-key fields, *Connex* only guarantees reception of the most recent data from the multi-channel *DataWriter*.

## 36.6.2 Reliable Protocol Considerations

Reliability is maintained on a per-channel basis. Each channel has its own reliability channel send window:

- **low\_watermark** and **high\_watermark**: The low and high watermarks control the send-window levels (when not using batching, this is a number of DDS samples; when using batching, this is a number of batches) that determine when to switch between regular and fast heartbeat rates (see [47.5.1 High and Low Watermarks on page 793](#)). With multi-channel *DataWriters*, **high\_watermark** and **low\_watermark** are computed from the channel with the smaller send-window size and they apply to all the channels. Therefore, because the watermark is determined by the channel with the smallest send-window, periodic heartbeating cannot be controlled on a per-channel basis.
- **heartbeats\_per\_max\_samples**: This field defines the number of piggyback heartbeats per current send-window. For multi-channel *DataWriters*, piggyback heartbeats are sent per channel. The send-window size that is used to calculate the piggyback heartbeat rate is the smallest across all channels..

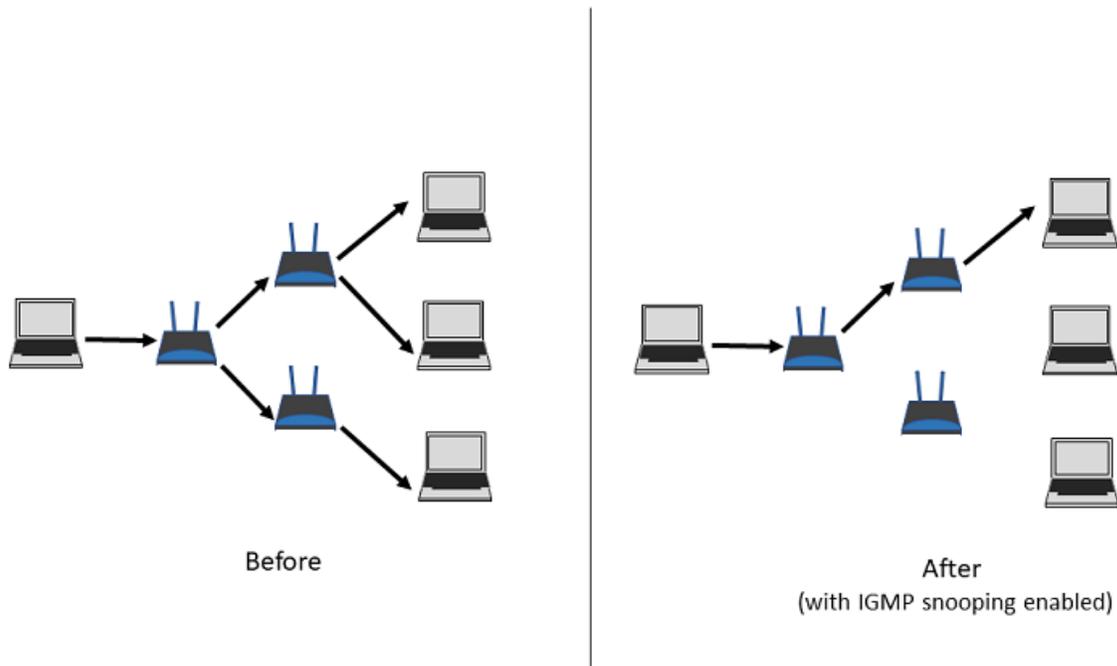

## 36.7 Performance Considerations

### 36.7.1 Network-Switch Filtering

By default, multicast traffic is treated as broadcast traffic by layer 2 switches. To avoid flooding the network with broadcast traffic and take full advantage of network filtering, the layer 2 switches should be configured to use IGMP snooping. Refer to your switch's manual for specific instructions.

When IGMP snooping is enabled, a switch can route a multicast packet to just those ports that subscribe to it, as seen in [Figure 36.6: IGMP Snooping on the next page](#).

Figure 36.6: IGMP Snooping

## 36.7.2 DataWriter and DataReader Filtering

[36.4 Where Does the Filtering Occur? on page 583](#) describes the three places where filtering can occur with Multi-channel *DataWriters*. To improve performance when filtering occurs on the reader and/or writer sides, use filter expressions that are only based on keys (see [Chapter 8 DDS Samples, Instances, and Keys on page 17](#)). Then the results of the filter are cached in a hash table on a per-key basis.

Market Data Example, continued:

The filter expressions in the Market Data example are based on the value of the field, **Symbol**. To make filter operations on this field more efficient, declare **Symbol** as a key. For example:

```
struct {
    @key string<MAX_SYMBOL_SIZE> Symbol;
}
```

You can also improve performance by increasing the number of buckets associated with the hash table. To do so, use the **instance\_hash\_buckets** field in the [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#) on both the writer and reader sides. A higher number of buckets will provide better performance, but requires more resources.

# Chapter 37 Collaborative DataWriters (Maintain Global, Ordered Set of Samples)

The *Collaborative DataWriters* feature allows you to have multiple *DataWriters* publishing DDS samples from a common logical data source. The *DataReaders* will combine the DDS samples coming from these *DataWriters* in order to reconstruct the correct order in which they were produced at the source. This combination process for the *DataReaders* can be configured using the [47.1 AVAILABILITY QosPolicy \(DDS Extension\) on page 769](#). It requires the middleware to provide a way to uniquely identify every DDS sample published in a DDS domain independently of the actual *DataWriter* that published the DDS sample.

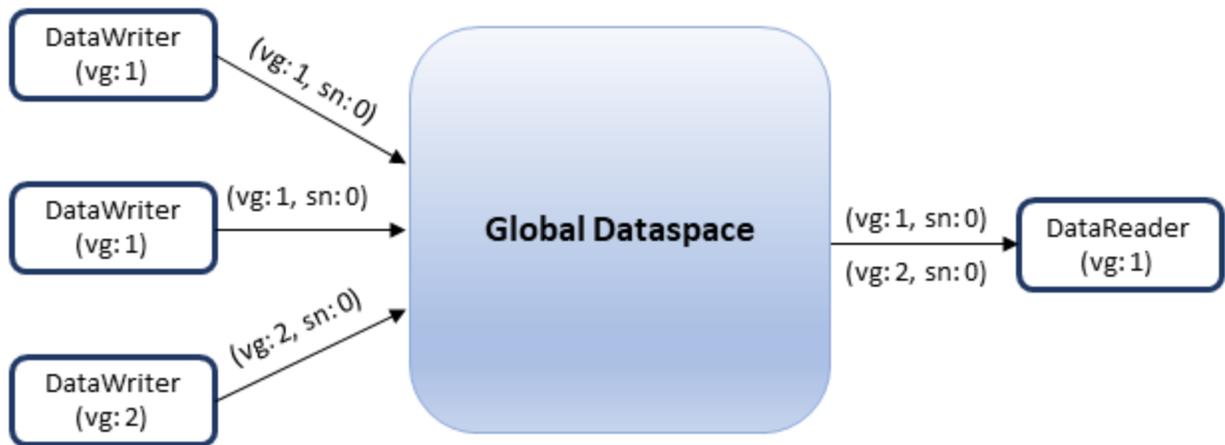

In *Connex*, every modification (DDS sample) to the global dataspace made by a *DataWriter* within a DDS domain is identified by a pair (virtual GUID, sequence number).

The virtual GUID (Global Unique Identifier) is a 16-byte character identifier associated with the logical data source. *DataWriters* can be assigned a virtual GUID using **virtual\_guid** in the [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 788](#).

The virtual sequence number is a 64-bit integer that identifies changes within the logical data source.

Several *DataWriters* can be configured with the same virtual GUID. If each of these *DataWriters* publishes a DDS sample with sequence number '0', the DDS sample will only be received once by the *DataReaders* subscribing to the content published by the *DataWriters* (see [Figure 37.1: Global Dataspace Changes on the next page](#)).

Figure 37.1: Global Dataspace Changes

## 37.1 Collaborative DataWriters Use Cases

- Ordered delivery of DDS samples in high availability scenarios

One example of this is *RTI Persistence Service*<sup>1</sup>. When a late-joining *DataReader* configured with [47.9 DURABILITY QosPolicy on page 809](#) set to PERSISTENT or TRANSIENT joins a DDS domain, it will start receiving DDS samples from multiple *DataWriters*. For example, if the original *DataWriter* is still alive, the newly created *DataReader* will receive DDS samples from the original *DataWriter* and one or more *RTI Persistence Service DataWriters* (PRSTDataWriters).

- Ordered delivery of DDS samples in load-balanced scenarios

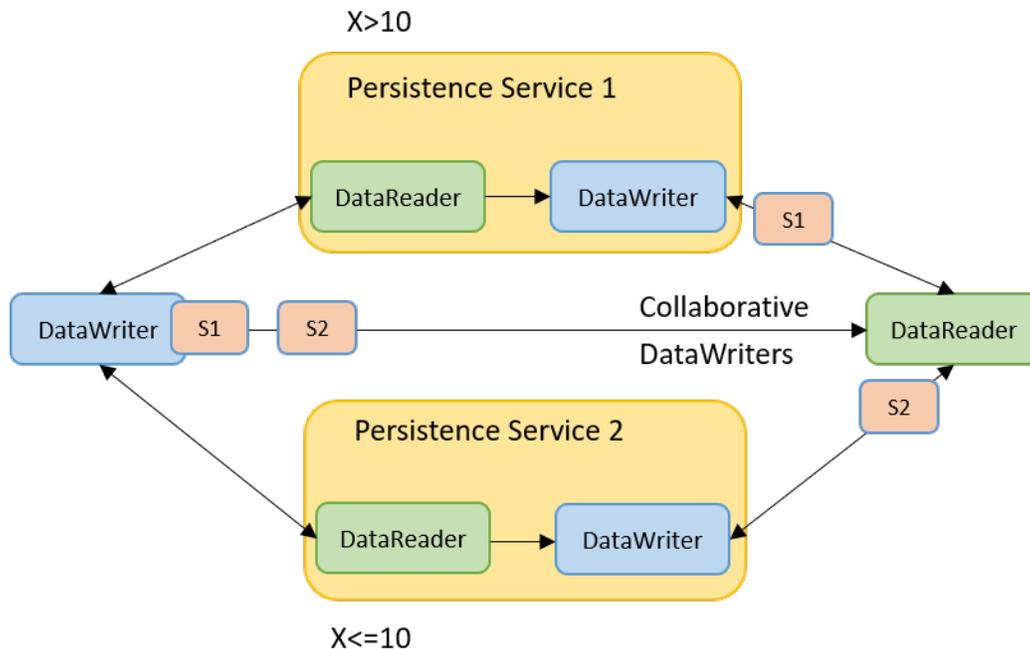

Multiple instances of the same application can work together to process and deliver DDS samples. When the DDS samples arrive through different data-paths out of order, the *DataReader* will be able to reconstruct the order at the source. An example of this is when multiple instances of *RTI Persistence Service* are used to persist the data. Persisting data to a database on disk can impact performance. By dividing the workload (e.g., DDS samples larger than 10 are persisted by Persistence Service 1, DDS samples smaller or equal to 10 are persisted by Persistence Service 2) across different instances of *RTI Persistence Service* using different databases the user can improve scalability and performance.

- Ordered delivery of DDS samples with Group Ordered Access

<sup>1</sup>For more information on *Persistence Service*, see [Part 12: RTI Persistence Service on page 1205](#).

The Collaborative DataWriters feature can also be used to configure the DDS sample ordering process when the *Subscriber* is configured with [46.6 PRESENTATION QosPolicy on page 760](#) `access_scope` set to GROUP. In this case, the *Subscriber* must deliver in order the DDS samples published by a group of *DataWriters* that belong to the same *Publisher* and have `access_scope` set to GROUP.

Figure 37.2: Load-Balancing with Persistence Service

## 37.2 Sample Combination (Synchronization) Process in a DataReader

A *DataReader* will deliver a DDS sample (VGUID<sub>n</sub>, VSN<sub>m</sub>) to the application only when if one of the following conditions is satisfied:

- (VGUID<sub>n</sub>, VSN<sub>m-1</sub>) has already been delivered to the application.
- All the known *DataWriters* publishing VGUID<sub>n</sub> have announced that they do not have (VGUID<sub>n</sub>, VSN<sub>m-1</sub>).
- None of the known *DataWriters* publishing VGUID<sub>n</sub> have announced potential availability of (VGUID<sub>n</sub>, VSN<sub>m-1</sub>) and a configurable timeout (`max_data_availability_waiting_time`) expires.

For additional details on how the reconstruction process works see the [47.1 AVAILABILITY QosPolicy \(DDS Extension\) on page 769](#).

## 37.3 Configuring Collaborative DataWriters

### 37.3.1 Associating Virtual GUIDs with DDS Data Samples

There are two ways to associate a virtual GUID with the DDS samples published by a *DataWriter*.

- Per *DataWriter*: Using **virtual\_guid** in [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 788](#).
- Per DDS Sample: By setting the **writer\_guid** in the identity field of the `WriteParams_t` structure provided to the **write\_w\_params** operation (see [31.8 Writing Data on page 410](#)). Since the **writer\_guid** can be set per DDS sample, the same *DataWriter* can potentially write DDS samples from independent logical data sources. One example of this is *RTI Persistence Service* where a single persistence service *DataWriter* can write DDS samples on behalf of multiple original *DataWriters*.

### 37.3.2 Associating Virtual Sequence Numbers with DDS Data Samples

You can associate a virtual sequence number with a DDS sample published by a *DataWriter* by setting the **sequence\_number** in the **identity** field of the `WriteParams_t` structure provided to the **write\_w\_params** operation (see [31.8 Writing Data on page 410](#)). Virtual sequence numbers for a given virtual GUID must be strictly monotonically increasing. If you try to write a DDS sample with a sequence number less than or equal to the last sequence number, the write operation will fail.

### 37.3.3 Specifying which DataWriters will Deliver DDS Samples to the DataReader from a Logical Data Source

The **required\_matched\_endpoint\_groups** field in the [47.1 AVAILABILITY QosPolicy \(DDS Extension\) on page 769](#) can be used to specify the set of *DataWriter* groups that are expected to provide DDS samples for the same data source (virtual GUID). The quorum count in a group represents the number of *DataWriters* that must be discovered for that group before the *DataReader* is allowed to provide non-consecutive DDS samples to the application.

A *DataWriter* becomes a member of an endpoint group by configuring the **role\_name** in [47.11 ENTITY\\_NAME QosPolicy \(DDS Extension\) on page 817](#).

### 37.3.4 Specifying How Long to Wait for a Missing DDS Sample

A *DataReader*'s [47.1 AVAILABILITY QosPolicy \(DDS Extension\) on page 769](#) specifies how long to wait for a missing DDS sample. For example, this is important when the first DDS sample is received: how long do you wait to determine the lowest sequence number available in the system?

- The **max\_data\_availability\_waiting\_time** defines how much time to wait before delivering a DDS sample to the application without having received some of the previous DDS samples.

- The **max\_endpoint\_availability\_waiting\_time** defines how much time to wait to discover *DataWriters* providing DDS samples for the same data source (virtual GUID).

## 37.4 Collaborative DataWriters and Persistence Service

The *DataWriters* created by persistence service are automatically configured to do collaboration:

- Every DDS sample published by the *Persistence Service DataWriter* keeps its original identity.
- *Persistence Service* associates the role name PERSISTENCE\_SERVICE with all the *DataWriters* that it creates. You can overwrite that setting by changing the *DataWriter* QoS configuration in persistence service.

For more information, see [Part 12: RTI Persistence Service on page 1205](#).

# Part 6: Receiving Data with Connex

This section includes:

- [Overview of Receiving Data \(Chapter 38 on page 594\)](#)
- [Subscribers \(Chapter 39 on page 597\)](#)
- [DataReaders \(Chapter 40 on page 615\)](#)
- [Using DataReaders to Access Data \(Read & Take\) \(Chapter 41 on page 663\)](#)

## Chapter 38 Overview of Receiving Data

This section discusses how to create, configure, and use *Subscribers* and *DataReaders* to receive data. It describes how these objects interact, as well as the types of operations that are available for them.

The goal of this section is to help you become familiar with the Entities you need for receiving data. For up-to-date details such as formal parameters and return codes on any mentioned operations, please see the *Connex* API Reference HTML documentation.

There are three ways to receive data:

- Your application can explicitly check for new data by calling a *DataReader*'s **read()** or **take()** operation. This method is also known as *polling for data*.
- Your application can be notified asynchronously whenever new DDS data samples arrive—this is done with a *Listener* on either the *Subscriber* or the *DataReader*. *Connex* will invoke the *Listener*'s callback routine when there is new data. Within the callback routine, user code can access the data by calling **read()** or **take()** on the *DataReader*. This method is the way for your application to receive data with the least amount of latency.
- Your application can wait for new data by using *Conditions* and a *WaitSet*, then calling **wait()**. *Connex* will block your application's thread until the criteria (such as the arrival of DDS samples, or a specific status) set in the *Condition* becomes true. Then your application resumes and can access the data with **read()** or **take()**.

The *DataReader*'s **read()** operation gives your application a copy of the data and leaves the data in the *DataReader*'s receive queue. The *DataReader*'s **take()** operation removes data from the receive queue before giving it to your application.

See [Chapter 41 Using DataReaders to Access Data \(Read & Take\) on page 663](#) for details on using *DataReaders* to access received data.

See [15.9 Conditions and WaitSets on page 59](#) for details on using *Conditions* and *WaitSets*.

**To prepare to receive data, create and configure the required Entities:**

1. Create a *DomainParticipant*.
2. Register user data types<sup>1</sup> with the *DomainParticipant*. For example, the **'FooDataType'**.
3. Use the *DomainParticipant* to create a *Topic* with the registered data type.
4. Optionally<sup>2</sup>, use the *DomainParticipant* to create a *Subscriber*.
5. Use the *Subscriber* or *DomainParticipant* to create a *DataReader* for the *Topic*.
6. Use a type-safe method to cast the generic *DataReader* created by the *Subscriber* to a type-specific *DataReader*. For example, **'FooDataReader'**.

Then use one of the following mechanisms to receive data.

- To receive DDS data samples by polling for new data:
    - Using a **FooDataReader**, use the **read()** or **take()** operations to access the DDS data samples that have been received and stored for the *DataReader*. These operations can be invoked at any time, even if the receive queue is empty.
  - To receive DDS data samples asynchronously:
    - Install a *Listener* on the *DataReader* or *Subscriber* that will be called back by an internal *Connex* thread when new DDS data samples arrive for the *DataReader*.
1. Create a *DDSDataReaderListener* for the *FooDataReader* or a *DDSSubscriberListener* for *Subscriber*. In C++ and Java, you must derive your own *Listener* class from those base classes. In C#, you can directly add your handlers to associated events in each entity that supports them. In C, you must create the individual functions and store them in a structure.

If you created a *DDSDataReaderListener* with the **on\_data\_available()** callback enabled: **on\_data\_available()** will be called when new data arrives for that *DataReader*.

If you created a *DDSSubscriberListener* with the **on\_data\_on\_readers()** callback enabled: **on\_data\_on\_readers()** will be called when data arrives for any *DataReader* created by the *Subscriber*.

2. Install the *Listener* on either the **FooDataReader** or *Subscriber*.

---

<sup>1</sup>Type registration is not required for built-in types (see [17.2.1 Registering Built-in Types on page 122](#)).

<sup>2</sup>You are not required to explicitly create a *Subscriber*; instead, you can use the 'implicit *Subscriber*' created from the *DomainParticipant*. See [39.1 Creating Subscribers Explicitly vs. Implicitly on page 600](#).

For the *DataReader*, the *Listener* should be installed to handle changes in the **DATA\_AVAILABLE** status.

For the *Subscriber*, the *Listener* should be installed to handle changes in the **DATA\_ON\_READERS** status.

3. Only 1 *Listener* will be called back when new data arrives for a *DataReader*.

*Connex* will call the *Subscriber's Listener* if it is installed. Otherwise, the *DataReader's Listener* is called if it is installed. That is, the **on\_data\_on\_readers()** operation takes precedence over the **on\_data\_available()** operation.

If neither *Listeners* are installed or neither *Listeners* are enabled to handle their respective statuses, then *Connex* will not call any user functions when new data arrives for the *DataReader*.

4. In the **on\_data\_available()** method of the *DDSDataReaderListener*, invoke **read()** or **take()** on the **FooDataReader** to access the data.

If the **on\_data\_on\_readers()** method of the *DDSSubscriberListener* is called, the code can invoke **read()** or **take()** directly on the *Subscriber's DataReaders* that have received new data. Alternatively, the code can invoke the *Subscriber's notify\_datareaders()* operation. This will in turn call the **on\_data\_available()** methods of the *DataReaderListeners* (if installed and enabled) for each of the *DataReaders* that have received new DDS data samples.

### To wait (block) until DDS data samples arrive:

1. Use the *DataReader* to create a *ReadCondition* that describes the DDS samples for which you want to wait. For example, you can specify that you want to wait for never-before-seen DDS samples from *DataReaders* that are still considered to be 'alive.'

Alternatively, you can create a *StatusCondition* that specifies you want to wait for the **ON\_DATA\_AVAILABLE** status.

2. Create a *WaitSet*.
3. Attach the *ReadCondition* or *StatusCondition* to the *WaitSet*.
4. Call the *WaitSet's wait()* operation, specifying how long you are willing to wait for the desired DDS samples. When **wait()** returns, it will indicate that it timed out, or that the attached *Condition* become true (and therefore the desired DDS samples are available).
5. Using a **FooDataReader**, use the **read()** or **take()** operations to access the DDS data samples that have been received and stored for the *DataReader*.

# Chapter 39 Subscribers

An application that intends to subscribe to information needs the following *Entities*: *DomainParticipant*, *Topic*, *Subscriber*, and *DataReader*. All *Entities* have a corresponding specialized *Listener* and a set of *QosPolicies*. The *Listener* is how *Connex* notifies your application of status changes relevant to the *Entity*. The *QosPolicies* allow your application to configure the behavior and resources of the *Entity*.

- The *DomainParticipant* defines the DDS domain on which the information will be available.
- The *Topic* defines the name of the data to be subscribed, as well as the type (format) of the data itself.
- The *DataReader* is the *Entity* used by the application to subscribe to updated values of the data. The *DataReader* is bound at creation time to a *Topic*, thus specifying the named and typed data stream to which it is subscribed. The application uses the *DataReader*'s **read()** or **take()** operation to access DDS data samples received for the *Topic*.
- The *Subscriber* manages the activities of several *DataReader* entities. The application receives data using a *DataReader* that belongs to a *Subscriber*. However, the *Subscriber* will determine when the data received from applications is actually available for access through the *DataReader*. Depending on the settings of various *QosPolicies* of the *Subscriber* and *DataReader*, data may be buffered until DDS data samples for associated *DataReaders* are also received. By default, the data is available to the application as soon as it is received.

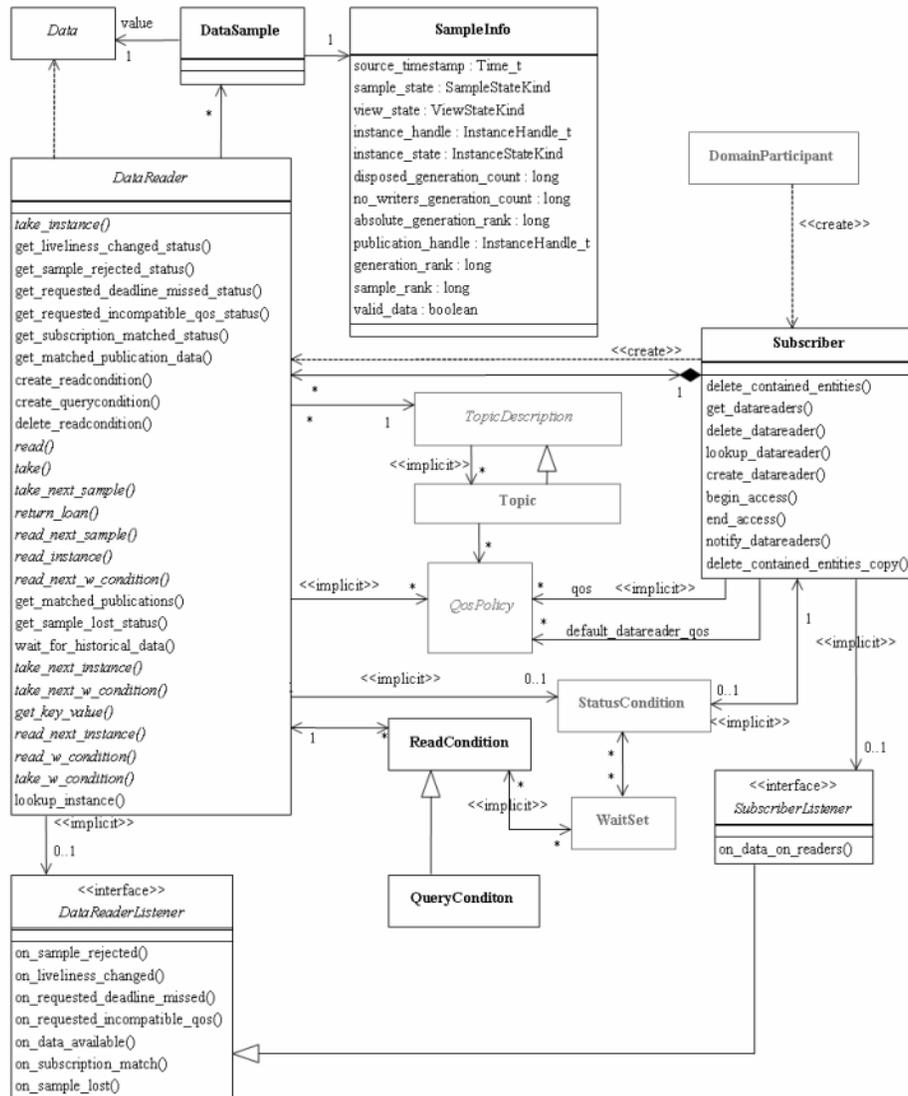

For more information, see [39.1 Creating Subscribers Explicitly vs. Implicitly on page 600](#).

The UML diagram in [Figure 39.1: Subscription Module on the next page](#) shows how these *Entities* are related as well as the methods defined for each *Entity*.

*Subscribers* are used to perform the operations listed in [Table 39.1 Subscriber Operations](#). For details such as formal parameters and return codes, please see the [API Reference HTML](#)

documentation. Otherwise, you can find more information about the operations by looking in the section listed under the [Reference on the next page](#) column.

Figure 39.1: Subscription Module

**Note:** Some operations cannot be used within a listener callback, see [15.8.8.1 Restricted Operations in Listener Callbacks](#) on page 57.

Table 39.1 Subscriber Operations

Working with ...	Operation	Description	Reference
DataReaders	begin_access	Indicates that the application is about to access the DDS data samples in the <i>DataReaders</i> of the <i>Subscriber</i> .	<a href="#">39.5 Beginning and Ending Group-Ordered Access on page 609</a>
	create_datareader	Creates a <i>DataReader</i> .	<a href="#">40.1 Creating DataReaders on page 620</a>
	create_datareader_with_profile	Creates a <i>DataReader</i> with QoS from a specified QoS profile.	
	copy_from_topic_qos	Copies relevant QoS policies from a <i>Topic</i> into a <i>DataReaderQoS</i> structure.	<a href="#">39.4.6 Subscriber QoS-Related Operations on page 608</a>
DataReaders cont'd	delete_contained_entities	Deletes all the <i>DataReaders</i> that were created by the <i>Subscriber</i> . Also deletes the corresponding <i>ReadConditions</i> created by the contained <i>DataReaders</i> .	<a href="#">39.3.1 Deleting Contained DataReaders on page 603</a>
	delete_datareader	Deletes a specific <i>DataReader</i> .	<a href="#">40.3 Deleting DataReaders on page 622</a>
	end_access	Indicates that the application is done accessing the DDS data samples in the <i>DataReaders</i> of the <i>Subscriber</i> .	<a href="#">39.5 Beginning and Ending Group-Ordered Access on page 609</a>
	get_all_datareaders	Retrieves all the <i>DataReaders</i> created from this <i>Subscriber</i> .	<a href="#">40.2 Getting All DataReaders on page 622</a>
	get_datareaders	Returns a list of <i>DataReaders</i> that contain DDS samples with the specified <b>sample_states</b> , <b>view_states</b> and <b>instance_states</b> .	<a href="#">39.7 Getting DataReaders with Specific DDS Samples on page 612</a>
	get_default_datareader_qos	Copies the <i>Subscriber's</i> default <i>DataReaderQoS</i> values into a <i>DataReaderQoS</i> structure.	<a href="#">39.4 Setting Subscriber QoS Policies on page 603</a>
DataReaders cont'd	get_status_changes	Gets all status changes.	<a href="#">15.4 Getting Status and Status Changes on page 38</a>
	lookup_datareader	Retrieves a <i>DataReader</i> previously created for a specific <i>Topic</i> .	<a href="#">39.8 Finding a Subscriber's Related Entities on page 612</a>
	notify_datareaders	Invokes the <code>on_data_available()</code> operation for attached <i>Listeners</i> of <i>DataReaders</i> that have new DDS data samples.	<a href="#">39.6 Setting Up SubscriberListeners on page 610</a>
	set_default_datareader_qos	Sets or changes the <i>Subscriber's</i> default <i>DataReaderQoS</i> values.	<a href="#">39.4 Setting Subscriber QoS Policies on page 603</a>

Table 39.1 Subscriber Operations

Working with ...	Operation	Description	Reference
Libraries and Profiles	get_default_library	Gets the <i>Subscriber's</i> default QoS profile library.	39.4.4 Getting and Settings Subscriber's Default QoS Profile and Library on page 607
	get_default_profile	Gets the <i>Subscriber's</i> default QoS profile.	
	get_default_profile_library	Gets the library that contains the <i>Subscriber's</i> default QoS profile.	
	set_default_library	Sets the default library for a <i>Subscriber</i> .	
	set_default_profile	Sets the default profile for a <i>Subscriber</i> .	
Participants	get_participant	Gets the <i>Subscriber's DomainParticipant</i> .	39.8 Finding a Subscriber's Related Entities on page 612
Subscribers	enable	Enables the <i>Subscriber</i> .	15.2 Enabling DDS Entities on page 35
	equals	Compares two <i>Subscriber's</i> QoS structures for equality.	39.4.2 Comparing QoS Values on page 606
	get_listener	Gets the currently installed <i>Listener</i> .	39.6 Setting Up SubscriberListeners on page 610
	get_qos	Gets the <i>Subscriber's</i> current QoSPolicy settings. This is most often used in preparation for calling set_qos.	39.4.3 Changing QoS Settings After Subscriber Has Been Created on page 606
	set_listener	Sets the <i>Subscriber's Listener</i> . If you created the Subscriber without a <i>Listener</i> , you can use this operation to add one later.	39.6 Setting Up SubscriberListeners on page 610
	set_qos	Sets the <i>Subscriber's</i> QoS. You can use this operation to change the values for the <i>Subscriber's</i> QoS Policies. Note, however, that not all QoS Policies can be changed after the <i>Subscriber</i> has been created.	39.4.3 Changing QoS Settings After Subscriber Has Been Created on page 606
	set_qos_with_profile	Sets the <i>Subscriber's</i> QoS based on a QoS profile.	39.4.3 Changing QoS Settings After Subscriber Has Been Created on page 606

## 39.1 Creating Subscribers Explicitly vs. Implicitly

To receive data, your application must have a *Subscriber*. However, you are not required to explicitly create a *Subscriber*. If you do not create one, the middleware will implicitly create a *Subscriber* the first time you create a *DataReader* using the *DomainParticipant's* operations. It will be created with default QoS (DDS\_SUBSCRIBER\_QOS\_DEFAULT) and no *Listener*. The 'implicit *Subscriber*' can be accessed using the *DomainParticipant's* `get_implicit_subscriber()` operation (see [16.3.10 Getting the Implicit Publisher or Subscriber on page 103](#)). You can use this 'implicit *Subscriber*' just like

any other *Subscriber* (it has the same operations, QoS policies, etc.). So you can change the mutable QoS and set a Listener if desired.

A *Subscriber* (implicit or explicit) gets its own default QoS and the default QoS for its child *DataReaders* from the *DomainParticipant*. These default QoS are set when the *Subscriber* is created. (This is true for *Publishers* and *DataWriters*, too.)

*DataReaders* are created by calling `create_datareader()` or `create_datareader_with_profile()`—these operations exist for *DomainParticipants* and *Subscribers*<sup>1</sup>. If you use the *DomainParticipant* to create a *DataReader*, it will belong to the implicit *Subscriber*. If you use a *Subscriber* to create a *DataReader*, it will belong to that *Subscriber*.

The middleware will use the same implicit *Subscriber* for all *DataReaders* that are created using the *DomainParticipant*'s operations.

Having the middleware implicitly create a *Subscriber* allows you to skip the step of creating a *Subscriber*. However, having all your *DataReaders* belong to the same *Subscriber* can reduce the concurrency of the system because all the read operations will be serialized.

## 39.2 Creating Subscribers

Before you can explicitly create a *Subscriber*, you need a *DomainParticipant* ([16.3 DomainParticipants on page 81](#)). To create a *Subscriber*, use the *DomainParticipant*'s `create_subscriber()` or `create_subscriber_with_profile()` operation.

A QoS profile is a way to use QoS settings from an XML file or string. With this approach, you can change QoS settings without recompiling the application. For details, see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

**Note:** The Modern C++ API provides *Subscriber* constructors whose first, and only required argument is the *DomainParticipant*.

```
DDSSubscriber* create_subscriber(
    const DDS_SubscriberQos &qos,
    DDSSubscriberListener * listener,
    DDS_StatusMask mask)
DDSSubscriber* create_subscriber_with_profile (
    const char * library_name,
    const char * profile_name,
    DDSSubscriberListener * listener,
    DDS_StatusMask mask )
```

Where:

---

<sup>1</sup>In the Modern C++ API, you always use a *DataReader* constructor.

<b>qos</b>	<p>If you want the default QoS settings (described in the API Reference HTML documentation), use <code>DDS_SUBSCRIBER_QOS_DEFAULT</code> for this parameter (see <a href="#">Figure 39.2: Creating a Subscriber with Default QoS Policies below</a>). If you want to customize any of the QoS Policies, supply a QoS structure (see <a href="#">Figure 39.3: Creating a Subscriber with Non-Default QoS Policies (not from a profile) on page 605</a>). The QoS structure for a <i>Subscriber</i> is described in <a href="#">Chapter 46 Publisher/Subscriber QoS Policies on page 740</a>.</p> <p><b>Note:</b> If you use <code>DDS_SUBSCRIBER_QOS_DEFAULT</code>, it is not safe to create the <i>Subscriber</i> while another thread may be simultaneously calling <code>set_default_subscriber_qos()</code>.</p>
<b>listener</b>	<p><i>Listeners</i> are callback routines. <i>Connex</i> uses them to notify your application when specific events (new DDS data samples arrive and status changes) occur with respect to the <i>Subscriber</i> or the <i>DataReaders</i> created by the <i>Subscriber</i>. The <i>listener</i> parameter may be set to <code>NULL</code> if you do not want to install a <i>Listener</i>. If you use <code>NULL</code>, the <i>Listener</i> of the <i>DomainParticipant</i> to which the <i>Subscriber</i> belongs will be used instead (if it is set). For more information on <i>SubscriberListeners</i>, see <a href="#">39.6 Setting Up SubscriberListeners on page 610</a>.</p>
<b>mask</b>	<p>This bit-mask indicates which status changes will cause the <i>Subscriber's Listener</i> to be invoked. The bits set in the mask must have corresponding callbacks implemented in the <i>Listener</i>. If you use <code>NULL</code> for the <i>Listener</i>, use <code>DDS_STATUS_MASK_NONE</code> for this parameter. If the <i>Listener</i> implements all callbacks, use <code>DDS_STATUS_MASK_ALL</code>. For information on Status, see <a href="#">15.8 Listeners on page 46</a>.</p> <p>This bit-mask indicates which status changes will cause the <i>Subscriber's Listener</i> to be invoked. The bits set in the mask must have corresponding callbacks implemented in the <i>Listener</i>. If you use <code>NULL</code> for the <i>Listener</i>, use <code>DDS_STATUS_MASK_NONE</code> for this parameter. If the <i>Listener</i> implements all callbacks, use <code>DDS_STATUS_MASK_ALL</code>. For information on Status, see <a href="#">15.8 Listeners on page 46</a>.</p>
<b>library_name</b>	A QoS Library is a named set of QoS profiles. See <a href="#">50.2 QoS Profiles on page 906</a> .
<b>profile_name</b>	A QoS profile groups a set of related QoS, usually one per entity. See <a href="#">50.2 QoS Profiles on page 906</a> .

**Figure 39.2: Creating a Subscriber with Default QoS Policies**

```
// create the subscriber
DDSSubscriber* subscriber =
    participant->create_subscriber(
        DDS_SUBSCRIBER_QOS_DEFAULT,
        NULL, DDS_STATUS_MASK_NONE);
if (subscriber == NULL) {
    // handle error
}
```

For more examples, see [39.4.1 Configuring QoS Settings when the Subscriber is Created on page 604](#).

After you create a *Subscriber*, the next step is to use the *Subscriber* to create a *DataReader* for each *Topic*, see [40.1 Creating DataReaders on page 620](#). For a list of operations you can perform with a *Subscriber*, see [Table 39.1 Subscriber Operations](#).

## 39.3 Deleting Subscribers

(Note: in the Modern C++ API, *Entities* are automatically destroyed, see [15.1 Creating and Deleting DDS Entities on page 33](#))

This section applies to both implicitly and explicitly created *Subscribers*.

To delete a *Subscriber*:

1. You must first delete all *DataReaders* that were created with the *Subscriber*. Use the *Subscriber*'s `delete_datareader()` operation ([40.1 Creating DataReaders on page 620](#)) to delete them one at a time, or use the `delete_contained_entities()` operation ([39.3.1 Deleting Contained DataReaders below](#)) to delete them all at the same time.

```
DDS_ReturnCode_t delete_datareader (DDSDataReader *a_datareader)
```

2. Delete the *Subscriber* by using the *DomainParticipant*'s `delete_subscriber()` operation ().

**Note:** A *Subscriber* cannot be deleted within a listener callback, see [15.8.8.1 Restricted Operations in Listener Callbacks on page 57](#).

### 39.3.1 Deleting Contained DataReaders

The *Subscriber*'s `delete_contained_entities()` operation deletes all the *DataReaders* that were created by the *Subscriber*. It also deletes the *ReadConditions* created by each contained *DataReader*.

```
DDS_ReturnCode_t DDSSubscriber::delete_contained_entities ()
```

After this operation returns successfully, the application may delete the *Subscriber* (see [39.3 Deleting Subscribers on the previous page](#)).

The operation will return `PRECONDITION_NOT_MET` if any of the contained entities cannot be deleted. This will occur, for example, if a contained *DataReader* cannot be deleted because the application has called `read()` but has not called the corresponding `return_loan()` operation to return the loaned DDS samples.

## 39.4 Setting Subscriber QoS Policies

A *Subscriber*'s QoS Policies control its behavior. Think of the policies as the configuration and behavior 'properties' for the *Subscriber*. The `DDS_SubscriberQos` structure has the following format:

```
struct DDS_SubscriberQos {
    DDS_PresentationQosPolicy    presentation;
    DDS_PartitionQosPolicy       partition;
    DDS_GroupDataQosPolicy       group_data;
    DDS_EntityFactoryQosPolicy   entity_factory;
    DDS_ExclusiveAreaQosPolicy    exclusive_area;
    DDS_EntityNameQosPolicy      subscriber_name;
};
```

**Note:** `set_qos()` cannot always be used by a *Listener*, see [15.8.8.1 Restricted Operations in Listener Callbacks on page 57](#).

[Table 39.2 Subscriber QoS Policies](#) summarizes the meaning of each policy. *Subscribers* have the same set of QoS Policies as *Publishers*; they are described in detail in [Chapter 46 Publisher/Subscriber QoS Policies on page 740](#). For information on *why* you would want to change a particular QoS Policy,

see the referenced section. For defaults and valid ranges, please refer to the API Reference HTML documentation for each policy.

**Table 39.2 Subscriber QoS Policies**

QoS Policy	Description
<a href="#">46.2 ENTITYFACTORY QoS Policy on page 743</a>	Whether or not new entities created from this entity will start out as 'enabled.'
<a href="#">47.11 ENTITY_NAME QoS Policy (DDS Extension) on page 817</a>	Assigns a name and role_name to a <i>Subscriber</i> .
<a href="#">46.3 EXCLUSIVE_AREA QoS Policy (DDS Extension) on page 746</a>	Whether or not the entity uses a multi-thread safe region with deadlock protection.
<a href="#">46.4 GROUP_DATA QoS Policy on page 748</a>	A place to pass group-level information among applications. Usage is application-dependent.
<a href="#">46.5 PARTITION QoS Policy on page 751</a>	Set of strings that introduces a logical partition among <i>Topics</i> visible by <i>Publisher/Subscriber</i> .
<a href="#">46.6 PRESENTATION QoS Policy on page 760</a>	The order in which instance changes are presented to the <i>Subscriber</i> . By default, no order is used.

## 39.4.1 Configuring QoS Settings when the Subscriber is Created

As described in [39.2 Creating Subscribers on page 601](#), there are different ways to create a *Subscriber*, depending on how you want to specify its QoS (with or without a QoS Profile).

- In [39.2 Creating Subscribers on page 601](#) is an example of how to explicitly create a *Subscriber* with default QoS Policies. It used the special constant, `DDS_SUBSCRIBER_QOS_DEFAULT`, which indicates that the default QoS values for a *Subscriber* should be used. The default *Subscriber* QoS Policies are configured in the *DomainParticipant*; you can change them with the *DomainParticipant*'s `set_default_subscriber_qos()` or `set_default_subscriber_qos_with_profile()` operation (see [16.3.7.5 Getting and Setting Default QoS for Child Entities on page 101](#)).
- To create a *Subscriber* with non-default QoS settings, without using a QoS profile, see [Figure 39.3: Creating a Subscriber with Non-Default QoS Policies \(not from a profile\) on the next page](#). It uses the *DomainParticipant*'s `get_default_subscriber_qos()` method to initialize a `DDS_SubscriberQos` structure. Then the policies are modified from their default values before the QoS structure is passed to `create_subscriber()`.
- You can also create a *Subscriber* and specify its QoS settings via a QoS Profile. To do so, call `create_subscriber_with_profile()`, as seen in [Figure 39.4: Creating a Subscriber with a QoS Profile on the next page](#).
- If you want to use a QoS profile, but then make some changes to the QoS before creating the *Subscriber*, call `get_subscriber_qos_from_profile()`, modify the QoS and use the modified QoS structure when calling `create_subscriber()`, as seen in [Figure 39.5: Getting QoS Values from a](#)

[Profile, Changing QoS Values, Creating a Subscriber with Modified QoS Values on the next page.](#)

For more information, see [39.2 Creating Subscribers on page 601](#) and [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

**Figure 39.3: Creating a Subscriber with Non-Default QoS Policies (not from a profile)**

```
DDS_SubscriberQos subscriber_qos;1
// get defaults
if (participant->get_default_subscriber_qos(subscriber_qos) !=
    DDS_RETCODE_OK){
// handle error
}
// make QoS changes here. for example, this changes the ENTITY_FACTORY QoS
subscriber_qos.entity_factory.autoenable_created_entities=DDS_BOOLEAN_FALSE;
// create the subscriber
DDSSubscriber * subscriber = participant->create_subscriber(subscriber_qos,
    NULL, DDS_STATUS_MASK_NONE);
if (subscriber == NULL) {
    // handle error
}
```

**Figure 39.4: Creating a Subscriber with a QoS Profile**

```
// create the subscriber with QoS profile
DDSSubscriber * subscriber = participant->create_subscriber_with_profile(
    "MySubscriberLibrary", "MySubscriberProfile", NULL, DDS_STATUS_MASK_NONE);
if (subscriber == NULL) {
    // handle error
}
```

---

<sup>1</sup>Note: In C, you must initialize the QoS structures before they are used, see [42.2 Special QoS Policy Handling Considerations for C on page 688](#).

**Figure 39.5: Getting QoS Values from a Profile, Changing QoS Values, Creating a Subscriber with Modified QoS Values**

```

DDS_SubscriberQos subscriber_qos;1
// Get subscriber QoS from profile
retcode = factory->get_subscriber_qos_from_profile(subscriber_qos,
    "SubscriberLibrary", "SubscriberProfile");
if (retcode != DDS_RETCODE_OK) {
    // handle error
}
// Makes QoS changes here
// for example, this changes the ENTITY_FACTORY QoS
subscriber_qos.entity_factory.autoenable_created_entities = DDS_BOOLEAN_TRUE;
// create the subscriber with modified QoS
DDSPublisher* subscriber = participant->create_subscriber(
    "Example Foo", type_name, subscriber_qos,
    NULL, DDS_STATUS_MASK_NONE);
if (subscriber == NULL) {
    // handle error
}

```

## 39.4.2 Comparing QoS Values

The `equals()` operation compares two *Subscriber*'s `DDS_SubscriberQoS` structures for equality. It takes two parameters for the two *Subscriber*'s QoS structures to be compared, then returns `TRUE` if they are equal (all values are the same) or `FALSE` if they are not equal.

## 39.4.3 Changing QoS Settings After Subscriber Has Been Created

There are 2 ways to change an existing *Subscriber*'s QoS after it has been created—again depending on whether or not you are using a QoS Profile.

- To change an existing *Subscriber*'s QoS programmatically (that is, without using a QoS profile), `get_qos()` and `set_qos()`. See the example code in [Figure 39.6: Changing the QoS of an Existing Subscriber on the next page](#). It retrieves the current values by calling the *Subscriber*'s `get_qos()` operation. Then it modifies the value and calls `set_qos()` to apply the new value. Note, however, that some `QoSPolicies` cannot be changed after the *Subscriber* has been enabled—this restriction is noted in the descriptions of the individual `QoSPolicies`.
- You can also change a *Subscriber*'s (and all other Entities') QoS by using a QoS Profile and calling `set_qos_with_profile()`. For an example, see [Figure 39.7: Changing the QoS of an Existing Subscriber with a QoS Profile on the next page](#). For more information, see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

<sup>1</sup>Note: In C, you must initialize the QoS structures before they are used, see [42.2 Special QoS Policy Handling Considerations for C on page 688](#).

Figure 39.6: Changing the Qos of an Existing Subscriber

```

DDS_SubscriberQos subscriber_qos;
// Get current QoS. subscriber points to an existing DDSSubscriber.
if (subscriber->get_qos(subscriber_qos) != DDS_RETCODE_OK) {
    // handle error
}
// make changes
// New entity_factory autoenable_created_entities will be true
subscriber_qos.entity_factory.autoenable_created_entities =
    DDS_BOOLEAN_TRUE;
// Set the new QoS
if (subscriber->set_qos(subscriber_qos) != DDS_RETCODE_OK ) {
    // handle error
}

```

Figure 39.7: Changing the QoS of an Existing Subscriber with a QoS Profile

```

retcode = subscriber->set_qos_with_profile(
    "SubscriberProfileLibrary","SubscriberProfile");
if (retcode != DDS_RETCODE_OK) {
    // handle error
}

```

### 39.4.4 Getting and Settings Subscriber's Default QoS Profile and Library

You can retrieve the default QoS profile used to create *Subscribers* with the `get_default_profile()` operation. You can also get the default library for *Subscribers*, as well as the library that contains the *Subscriber's* default profile (these are not necessarily the same library); these operations are called `get_default_library()` and `get_default_library_profile()`, respectively. These operations are for informational purposes only (that is, you do not need to use them as a precursor to setting a library or profile.) For more information, see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

```

virtual const char * get_default_library ()
const char * get_default_profile ()
const char * get_default_profile_library ()

```

There are also operations for setting the *Subscriber's* default library and profile:

```

DDS_ReturnCode_t set_default_library (
    const char * library_name)
DDS_ReturnCode_t set_default_profile (
    const char * library_name,
    const char * profile_name)

```

These operations only affect which library/profile will be used as the default the next time a default *Subscriber* library/profile is needed during a call to one of this *Subscriber's* operations.

When calling a *Subscriber* operation that requires a **profile\_name** parameter, you can use NULL to refer to the default profile. (This same information applies to setting a default library.)

If the default library/profile is not set, the *Subscriber* inherits the default from the *DomainParticipant*.

**set\_default\_profile()** does not set the default QoS for *DataReaders* created by the *Subscriber*; for this functionality, use the *Subscriber's* **set\_default\_datareader\_qos\_with\_profile()**, see [39.4.5 Getting and Setting Default QoS for DataReaders below](#) (you may pass in NULL after having called the *Subscriber's* **set\_default\_profile()**).

**set\_default\_profile()** does not set the default QoS for newly created *Subscribers*; for this functionality, use the *DomainParticipant's* **set\_default\_subscriber\_qos\_with\_profile()** operation, see [16.3.7.5 Getting and Setting Default QoS for Child Entities on page 101](#).

## 39.4.5 Getting and Setting Default QoS for DataReaders

These operations *set* the default QoS that will be used for new *DataReaders* if **create\_datareader()** is called with DDS\_DATAREADER\_QOS\_DEFAULT as the ‘qos’ parameter:

```
DDS_ReturnCode_t set_default_datareader_qos (const DDS_DataReaderQos &qos)
```

```
DDS_ReturnCode_t set_default_datareader_qos_with_profile (
    const char *library_name, const char *profile_name)
```

The above operations may potentially allocate memory, depending on the sequences contained in some QoS policies.

To *get* the default QoS that will be used for creating *DataReaders* if **create\_datareader()** is called with DDS\_DATAREADER\_QOS\_DEFAULT as the ‘qos’ parameter:

```
DDS_ReturnCode_t get_default_datareader_qos (DDS_DataReaderQos & qos)
```

The above operation gets the QoS settings that were specified on the last successful call to **set\_default\_datareader\_qos()** or **set\_default\_datareader\_qos\_with\_profile()**, or if the call was never made, the default values listed in DDS\_DataReaderQos.

**Note:** It is not safe to set the default *DataReader* QoS values while another thread may be simultaneously calling **get\_default\_datareader\_qos()**, **set\_default\_datareader\_qos()** or **create\_datareader()** with DDS\_DATAREADER\_QOS\_DEFAULT as the **qos** parameter. It is also not safe to get the default *DataReader* QoS values while another thread may be simultaneously calling **set\_default\_datareader\_qos()**.

## 39.4.6 Subscriber QoS-Related Operations

- **Copying a Topic’s QoS into a DataReader’s QoS**

This method is provided as a convenience for setting the values in a *DataReaderQos* structure before using that structure to create a *DataReader*. As explained in [18.1.3 Setting Topic QoS Policies on page 250](#), most of the policies in a *TopicQos* structure do not apply directly to the *Topic* itself, but to the associated *DataWriters* and *DataReaders* of that *Topic*. The *TopicQos* serves as a single container where the values of QoS Policies that must be set compatibly across matching *DataWriters* and *DataReaders* can be stored.

Thus instead of setting the values of the individual QoS policies that make up a *DataReaderQos* structure every time you need to create a *DataReader* for a *Topic*, you can use the *Subscriber*'s **copy\_from\_topic\_qos()** operation to “import” the *Topic*'s QoS policies into a *DataReaderQos* structure. This operation copies the relevant policies in the *TopicQos* to the corresponding policies in the *DataReaderQos*.

This copy operation will often be used in combination with the *Subscriber*'s **get\_default\_datareader\_qos()** and the *Topic*'s **get\_qos()** operations. The *Topic*'s QoS values are merged on top of the *Subscriber*'s default *DataReader* QoS policies with the result used to create a new *DataReader*, or to set the QoS of an existing one (see [40.9 Setting DataReader QoS Policies on page 652](#)).

- **Copying a Subscriber's QoS**

In the C API users should use the **DDS\_SubscriberQos\_copy()** operation rather than using structure assignment when copying between two QoS structures. The **copy()** operation will perform a deep copy so that policies that allocate heap memory such as sequences are copied correctly. In C++, C# and Java, a copy constructor is provided to take care of sequences automatically.

- **Clearing QoS-Related Memory**

Some QoS policies contain sequences that allocate memory dynamically as they grow or shrink. The C API's **DDS\_SubscriberQos\_finalize()** operation frees the memory used by sequences but otherwise leaves the QoS unchanged. C users should call **finalize()** on all **DDS\_SubscriberQos** objects before they are freed, or for QoS structures allocated on the stack, before they go out of scope. In C++, C# and Java, the memory used by sequences is freed in the destructor.

## 39.5 Beginning and Ending Group-Ordered Access

The *Subscriber*'s **begin\_access()** operation indicates that the application is about to access the DDS data samples in any of the *DataReaders* attached to the *Subscriber*.

If the *Subscriber*'s **access\_scope** (in the [46.6 PRESENTATION QoS Policy on page 760](#)) is **GROUP** or **HIGHEST\_OFFERED** and **ordered\_access** (also in the [46.6 PRESENTATION QoS Policy on page 760](#)) is **TRUE**, the application is required to use this operation to access the DDS samples in order across *DataWriters* of the same group (*Publisher* with **access\_scope** **GROUP**).

In the above case, **begin\_access()** must be called prior to calling any of the sample-accessing operations: **get\_datareaders()** on the *Subscriber*, and **read()**, **take()**, **read\_w\_condition()**, and **take\_w\_condition()** on any *DataReader*.

Once the application has finished accessing the DDS data samples, it must call **end\_access()**. To see how to read samples in order when the *Subscriber*'s **begin\_access()** operation is called, see [39.7 Getting DataReaders with Specific DDS Samples on page 612](#).

The application is not required to call **begin\_access()** and **end\_access()** to access the DDS samples in order if the *Publisher's* **access\_scope** is something other than GROUP. In this case, calling **begin\_access()** and **end\_access()** is not considered an error and has no effect.

Calls to **begin\_access()** and **end\_access()** may be nested and must be balanced. That is, **end\_access()** close a previous call to **begin\_access()**.

## 39.6 Setting Up SubscriberListeners

Like all Entities, *Subscribers* may optionally have *Listeners*. *Listeners* are user-defined objects that implement a DDS-defined interface (i.e. a pre-defined set of callback functions). *Listeners* provide the means for *Connex* to notify applications of any changes in *Statuses* (events) that may be relevant to it. By writing the callback functions in the *Listener* and installing the *Listener* into the *Subscriber*, applications can be notified to handle the events of interest. For more general information on *Listeners* and *Statuses*, see [15.8 Listeners on page 46](#).

Note: Some operations cannot be used within a listener callback, see [15.8.8.1 Restricted Operations in Listener Callbacks on page 57](#).

As illustrated in [Figure 39.1: Subscription Module on page 598](#), the *SubscriberListener* interface extends the *DataReaderListener* interface. In other words, the *SubscriberListener* interface contains all the functions in the *DataReaderListener* interface. In addition, a *SubscriberListener* has an additional function: **on\_data\_on\_readers()**, corresponding to the *Subscriber's* **DATA\_ON\_READERS** status. This is the only status that is specific to a *Subscriber*. This status is closely tied to the **DATA\_AVAILABLE** status ([40.7.1 DATA\\_AVAILABLE Status on page 627](#)) of *DataReaders*.

The *Subscriber's* **DATA\_ON\_READERS** status is set whenever the **DATA\_AVAILABLE** status is set for any of the *DataReaders* created by the *Subscriber*. This implies that one of its *DataReaders* has received new DDS data samples. When the **DATA\_ON\_READERS** status is set, the *SubscriberListener's* **on\_data\_on\_readers()** method will be invoked.

The **DATA\_ON\_READERS** status of a *Subscriber* takes precedence over the **DATA\_AVAILABLE** status of any of its *DataReaders*. Thus, when data arrives for a *DataReader*, the **on\_data\_on\_readers()** operation of the *SubscriberListener* will be called instead of the **on\_data\_available()** operation of the *DataReaderListener*—assuming that the *Subscriber* has a *Listener* installed that is enabled to handle changes in the **DATA\_ON\_READERS** status. (Note however, that in the *SubscriberListener's* **on\_data\_on\_readers()** operation, you may choose to call **notify\_datareaders()**, which in turn may cause the *DataReaderListener's* **on\_data\_available()** operation to be called.)

All of the other methods of a *SubscriberListener* will be called back for changes in the *Statuses* of *Subscriber's* *DataReaders* only if the *DataReader* is not set up to handle the statuses itself.

If you want a *Subscriber* to handle status events for its *DataReaders*, you can set up a *SubscriberListener* during the *Subscriber's* creation or use the **set\_listener()** method after the *Subscriber* is

created. The last parameter is a bit-mask with which you should set which *Status* events that the *SubscriberListener* will handle. For example,

```
DDS_StatusMask mask =
    DDS_REQUESTED_DEADLINE_MISSED_STATUS |
    DDS_REQUESTED_INCOMPATIBLE_QOS_STATUS;
subscriber = participant->create_subscriber(
    DDS_SUBSCRIBER_QOS_DEFAULT, listener, mask);
```

or

```
DDS_StatusMask mask =
    DDS_REQUESTED_DEADLINE_MISSED_STATUS |
    DDS_REQUESTED_INCOMPATIBLE_QOS_STATUS;
subscriber->set_listener(listener, mask);
```

As previously mentioned, the callbacks in the *SubscriberListener* act as ‘default’ callbacks for all the *DataReaders* contained within. When *Connex*t wants to notify a *DataReader* of a relevant *Status* change (for example, **SUBSCRIPTION\_MATCHED**), it first checks to see if the *DataReader* has the corresponding *DataReaderListener* callback enabled (such as the **on\_subscription\_matched()** operation). If so, *Connex*t dispatches the event to the *DataReaderListener* callback. Otherwise, *Connex*t dispatches the event to the corresponding *SubscriberListener* callback.

**NOTE**, the reverse is true for the **DATA\_ON\_READERS/DATA\_AVAILABLE** status. When **DATA\_AVAILABLE** changes for any *DataReaders* of a *Subscriber*, *Connex*t first checks to see if the *SubscriberListener* has **DATA\_ON\_READERS** enabled. If so, *Connex*t will invoke the **on\_data\_on\_readers()** callback. Otherwise, *Connex*t dispatches the event to the *Listener* (**on\_data\_available()**) of the *DataReader* whose **DATA\_AVAILABLE** status actually changed.

A particular callback in a *DataReader* is *not* enabled if either:

- The application installed a NULL *DataReaderListener* (meaning there are *no* callbacks for the *DataReader* at all).
- The application has disabled the callback for a *DataReaderListener*. This is done by turning off the associated status bit in the *mask* parameter passed to the **set\_listener()** or **create\_datareader()** call when installing the *DataReaderListener* on the *DataReader*. For more information on *DataReaderListener*, see [40.4 Setting Up DataReaderListeners on page 622](#).

Similarly, the callbacks in the *DomainParticipantListener* act as ‘default’ callbacks for all the *Subscribers* that belong to it. For more information on *DomainParticipantListeners*, see [16.3.6 Setting Up DomainParticipantListeners on page 94](#).

The *Subscriber* also provides an operation called **notify\_datareaders()** that can be used to invoke the **on\_data\_available()** callbacks of *DataReaders* who have new DDS data samples in their receive queues. Often **notify\_datareaders()** will be used in the **on\_data\_on\_readers()** callback to pass off the real processing of data from the *SubscriberListener* to the individual *DataReaderListeners*.

Calling **notify\_datareaders()** causes the **DATA\_ON\_READERS** status to be reset.

Figure 39.8: Simple SubscriberListener below shows a *SubscriberListener* that simply notifies its *DataReaders* when new data arrives.

Figure 39.8: Simple SubscriberListener

```
class MySubscriberListener : public DDSSubscriberListener {
public:
    void on_data_on_readers(DDSSubscriber *);
/* For this example we take no action other operations */
};
void MySubscriberListener::on_data_on_readers (DDSSubscriber *subscriber)
{
    // do global processing
    ...
    // now dispatch data arrival event to specific DataReaders
    subscriber->notify_datareaders();
}
```

## 39.7 Getting DataReaders with Specific DDS Samples

The *Subscriber's* `get_datareaders()` operation retrieves a list of *DataReaders* that have DDS samples with specific **sample\_states**, **view\_states**, and **instance\_states**.

If the application is outside a `begin_access()/end_access()` block, or if the *Subscriber's* **access\_scope** (in the 46.6 PRESENTATION QoSPolicy on page 760) is INSTANCE or TOPIC, or **ordered\_access** (also in the 46.6 PRESENTATION QoSPolicy on page 760) is FALSE, the returned collection is a 'set' containing each *DataReader* at most once, in no specified order.

If the application is within a `begin_access()/end_access()` block, and the *Subscriber's* **access\_scope** is GROUP or HIGHEST\_OFFERED, and **ordered\_access** is TRUE, the returned collection is a 'list' of *DataReaders*, where a *DataReader* may appear more than one time.

To retrieve the DDS samples in the order in which they were published across *DataWriters* of the same group (a *Publisher* configured with GROUP **access\_scope**), the application should `read()/take()` from each *DataReader* in the same order as appears in the output sequence. The application will move to the next *DataReader* when the `read()/take()` operation fails with NO\_DATA.

```
DDS_ReturnCode_t get_datareaders (DDSDataReaderSeq & readers,
    DDS_SampleStateMask    sample_states,
    DDS_ViewStateMask     view_states,
    DDS_InstanceStateMask instance_states)
```

For more information, see 41.6 The SampleInfo Structure on page 676.

## 39.8 Finding a Subscriber's Related Entities

These *Subscriber* operations are useful for obtaining a handle to related entities:

- **get\_participant()**: Gets the *DomainParticipant* with which a *Subscriber* was created.
- **lookup\_datareader()**: Finds a *DataReader* created by the *Subscriber* with a *Topic* of a particular name. Note that if multiple *DataReaders* were created by the same *Subscriber* with the same *Topic*, any one of them may be returned by this method.

You can use this operation on a built-in *Subscriber* to access the built-in *DataReaders* for the built-in topics. The built-in *DataReader* is created when this operation is called on a built-in topic for the first time.

If you are going to modify the transport properties for the built-in *DataReaders*, do so *before* using this operation. Built-in transports are implicitly registered when the *DomainParticipant* is enabled or the first *DataWriter/DataReader* is created. To ensure that built-in *DataReaders* receive all the discovery traffic, you should lookup the *DataReader* before the *DomainParticipant* is enabled. Therefore the suggested sequence when looking up built-in *DataReaders* is:

1. Create a disabled *DomainParticipant* (see [46.2 ENTITYFACTORY QosPolicy on page 743](#)).
  2. If you want to use non-default values, modify the built-in transport properties (see [51.5 Setting Builtin Transport Properties of Default Transport Instance—get/set\\_builtin\\_transport\\_properties\(\)](#) on page 959).
  3. Call **get\_builtin\_subscriber()** (see [28.2 Built-in DataReaders on page 360](#)).
  4. Call **lookup\_datareader()**.
  5. Call **enable()** on the *DomainParticipant* (see [15.2 Enabling DDS Entities on page 35](#)).
- **DDS\_Subscriber\_as\_Entity()**: This method is provided for C applications and is necessary when invoking the parent class *Entity* methods on *Subscribers*. For example, to call the *Entity* method **get\_status\_changes()** on a *Subscriber*, **my\_sub**, do the following:

```
DDS_Entity_get_status_changes(DDS_Subscriber_as_Entity(my_sub))
```

- **DDS\_Subscriber\_as\_Entity()** is not provided in the C++, C# and Java APIs because the object-oriented features of those languages make it unnecessary.

## 39.9 Statuses for Subscribers

The status indicators for a *Subscriber* are the same as those available for its *DataReaders*, with one additional status: **DATA\_ON\_READERS** ([39.9.1 DATA\\_ON\\_READERS Status on the next page](#)). The following statuses can be monitored by the *SubscriberListener*.

- [39.9.1 DATA\\_ON\\_READERS Status on the next page](#)
- [40.7.1 DATA\\_AVAILABLE Status on page 627](#)

- [40.7.4 LIVELINESS\\_CHANGED Status on page 634](#)
- [40.7.5 REQUESTED\\_DEADLINE\\_MISSED Status on page 635](#)
- [40.7.6 REQUESTED\\_INCOMPATIBLE\\_QOS Status on page 636](#)
- [40.7.7 SAMPLE\\_LOST Status on page 636](#)
- [40.7.8 SAMPLE\\_REJECTED Status on page 640](#)
- [40.7.9 SUBSCRIPTION\\_MATCHED Status on page 642](#)

You can access *Subscriber* status by using a *SubscriberListener* or its inherited `get_status_changes()` operation (see [15.4 Getting Status and Status Changes on page 38](#)), which can be used to explicitly poll for the `DATA_ON_READERS` status of the *Subscriber*.

### 39.9.1 DATA\_ON\_READERS Status

The `DATA_ON_READERS` status, like the `DATA_AVAILABLE` status for *DataReaders*, is a *read* communication status, which makes it somewhat different from other *plain* communication statuses. (See [15.7.1 Types of Communication Status on page 40](#) for more information on statuses and the difference between *read* and *plain* statuses.) In particular, there is no status-specific data structure; the status is either changed or not, there is no additional associated information.

The `DATA_ON_READERS` status indicates that there is new data available for one or more *DataReaders* that belong to this *Subscriber*. The `DATA_AVAILABLE` status for each such *DataReader* will also be updated.

The `DATA_ON_READERS` status is reset (the corresponding bit in the bitmask is turned off) when you call `read()`, `take()`, or one of their variations on *any* of the *DataReaders* that belong to the *Subscriber*. This is true even if the *DataReader* on which you call `read/take` is not the same *DataReader* that caused the `DATA_ON_READERS` status to be set in the first place. This status is also reset when you call `notify_datareaders()` on the *Subscriber*, or after `on_data_on_readers()` is invoked.

If a *SubscriberListener* has both `on_data_on_readers()` and `on_data_available()` callbacks enabled (by turning on both status bits), only `on_data_on_readers()` is called.

# Chapter 40 DataReaders

To create a *DataReader*, you need a *DomainParticipant*, a *Topic*, and optionally, a *Subscriber*. You need at least one *DataReader* for each *Topic* whose DDS data samples you want to receive.

After you create a *DataReader*, you will be able to use the operations listed in [Table 40.1 DataReader Operations](#). You are likely to use many of these operations from within your *DataReader's Listener*, which is invoked when there are status changes or new DDS data samples. For more details on all operations, see the API reference HTML documentation. The *DataReaderListener* is described in [40.4 Setting Up DataReaderListeners on page 622](#).

*DataReaders* are created by using operations on a *DomainParticipant* or a *Subscriber*, as described in [39.1 Creating Subscribers Explicitly vs. Implicitly on page 600](#). If you use the *DomainParticipant's* operations, the *DataReader* will belong to an implicit *Subscriber* that is automatically created by the middleware. If you use a *Subscriber's* operations, the *DataReader* will belong to that *Subscriber*. So either way, the *DataReader* belongs to a *Subscriber*.

**Note:** Some operations cannot be used within a listener callback, see [15.8.8.1 Restricted Operations in Listener Callbacks on page 57](#).

Table 40.1 DataReader Operations

Purpose	Operation	Description	Reference
Configuring the DataReader	enable	Enables the <i>DataReader</i> .	<a href="#">15.2 Enabling DDS Entities on page 35</a>
	equals	Compares two <i>DataReader</i> 's QoS structures for equality.	<a href="#">40.9.2 Comparing QoS Values on page 657</a>
	get_qos	Gets the QoS.	<a href="#">40.9 Setting DataReader QoS Policies on page 652</a>
	set_qos	Modifies the QoS.	
	set_qos_with_profile	Modifies the QoS based on a QoS profile.	
	get_listener	Gets the currently installed <i>Listener</i> .	<a href="#">40.4 Setting Up DataReaderListeners on page 622</a>
	set_listener	Replaces the <i>Listener</i> .	
Accessing DDS Data Samples with "Read" (Use <code>FooData-Reader</code> , see <a href="#">41.3 Accessing DDS Data Samples with Read or Take on page 665</a> )	read	Reads (copies) a collection of DDS data samples from the <i>DataReader</i> .	<a href="#">41.3 Accessing DDS Data Samples with Read or Take on page 665</a>
	read_instance	Identical to <code>read</code> , but all DDS samples returned belong to a single instance, which you specify as a parameter.	<a href="#">41.3.4 read_instance and take_instance on page 670</a>
	read_instance_w_condition	Identical to <code>read_instance</code> , but all DDS samples returned belong to a single instance <i>and</i> satisfy a specific <code>ReadCondition</code> .	<a href="#">41.3.7 read_instance_w_condition and take_instance_w_condition on page 672</a>
	read_next_instance	Similar to <code>read_instance</code> , but the actual instance is not directly specified as a parameter. Instead, the DDS samples will all belong to instance ordered after the one previously read.	<a href="#">41.3.5 read_next_instance and take_next_instance on page 670</a>
	read_next_instance_w_condition	Accesses a collection of DDS data samples of the next instance that match a specific set of <code>ReadConditions</code> , from the <i>DataReader</i> .	<a href="#">41.3.8 read_next_instance_w_condition and take_next_instance_w_condition on page 673</a>
	read_next_sample	Reads the next not-previously-accessed data value from the <i>DataReader</i> .	<a href="#">41.3.3 read_next_sample and take_next_sample on page 669</a>
	read_w_condition	Accesses a collection of DDS data samples from the <i>DataReader</i> that match specific <code>ReadCondition</code> criteria.	<a href="#">41.3.6 read_w_condition and take_w_condition on page 672</a>

Table 40.1 DataReader Operations

Purpose	Operation	Description	Reference
Accessing DDS Data Samples with "Take" (Use FooData-Reader, see <a href="#">41.3 Accessing DDS Data Samples with Read or Take on page 665</a> )	take	Like read, but the DDS samples are removed from the <i>DataReader's</i> receive queue.	<a href="#">41.3 Accessing DDS Data Samples with Read or Take on page 665</a>
	take_instance	Identical to take, but all DDS samples returned belong to a single instance, which you specify as a parameter.	<a href="#">41.3.4 read_instance and take_instance on page 670</a>
	take_instance_w_condition	Identical to take_instance, but all DDS samples returned belong to a single instance <i>and</i> satisfy a specific ReadCondition.	<a href="#">41.3.7 read_instance_w_condition and take_instance_w_condition on page 672</a>
	take_next_instance	Like read_next_instance, but the DDS samples are removed from the <i>DataReader's</i> receive queue.	<a href="#">41.3.5 read_next_instance and take_next_instance on page 670</a>
	take_next_instance_w_condition	Accesses (and removes) a collection of DDS data samples of the next instance that match a specific set of <i>ReadConditions</i> , from the <i>DataReader</i> .	<a href="#">41.3.8 read_next_instance_w_condition and take_next_instance_w_condition on page 673</a>
	take_next_sample	Like read_next_sample, but the DDS samples are removed from the <i>DataReader's</i> receive queue.	<a href="#">41.3.3 read_next_sample and take_next_sample on page 669</a>
Working with DDS Data Samples and FooData-Reader (Use FooData-Reader, see <a href="#">41.3 Accessing DDS Data Samples with Read or Take on page 665</a> )	take_w_condition	Accesses (and removes) a collection of DDS data samples from the <i>DataReader</i> that match specific <i>ReadCondition</i> criteria.	<a href="#">41.3.6 read_w_condition and take_w_condition on page 672</a>
	narrow	A type-safe way to cast a pointer. This takes a DDSDataReader pointer and 'narrows' it to a 'FooDataReader' where 'Foo' is the related data type.	<a href="#">41.1 Using a Type-Specific DataReader (FooDataReader) on page 663</a>
	return_loan	Returns buffers loaned in a previous read or take call.	<a href="#">41.2 Loaning and Returning Data and SampleInfo Sequences on page 664</a>
	get_key_value	Gets the key for an instance handle.	<a href="#">40.10.5 Getting the Key Value for an Instance on page 662</a>
	lookup_instance	Gets the instance handle that corresponds to an instance key.	<a href="#">40.10.4 Looking Up an Instance Handle on page 662</a>
Acknowledging DDS Samples	acknowledge_all	Acknowledge all previously accessed DDS samples.	<a href="#">41.4 Acknowledging DDS Samples on page 674</a>
	acknowledge_sample	Acknowledge a single DDS sample.	

Table 40.1 DataReader Operations

Purpose	Operation	Description	Reference
Checking Status	get_liveliness_ changed_ status	Gets LIVELINESS_CHANGED_STATUS status.	40.7 Statuses for DataReaders on page 626
	get_requested_ deadline_ missed_status	Gets REQUESTED_DEADLINE_MISSED_STATUS status.	
	get_requested_ incompatible_ qos_status	Gets REQUESTED_INCOMPATIBLE_QOS_STATUS status.	
	get_sample_lost_ status	Gets SAMPLE_LOST_STATUS status.	
	get_sample_rejected_ status	Gets SAMPLE_REJECTED_STATUS status.	
	get_subscription_ matched_ status	Gets SUBSCRIPTION_MATCHED_STATUS status.	15.4 Getting Status and Status Changes on page 38
	get_status_ changes	Gets a list of statuses that changed since last time the application read the status or the listeners were called.	
	get_datareader_ cache_ status	Gets DATA_READER_CACHE_STATUS status.	40.5 Checking DataReader Status and StatusConditions on page 624
	get_datareader_ protocol_ status	Gets DATA_READER_PROTOCOL_STATUS status.	
	get_matched_ publication_ datareader_ protocol_ status	Get the protocol status for this <i>DataReader</i> , per matched publication identified by the publication_handle.	40.7 Statuses for DataReaders on page 626

Table 40.1 DataReader Operations

Purpose	Operation	Description	Reference
Navigating Relationships	get_instance_handle	Returns the DDS_InstanceHandle_t associated with the Entity.	<a href="#">15.3 Getting an Entity's Instance Handle on page 37</a>
	get_matched_publication_data	Gets information on a publication with a matching Topic and compatible QoS.	<a href="#">40.10.1 Finding Matching Publications on page 660</a>
	get_matched_publications	Gets a list of publications that have a matching Topic and compatible QoS. These are the publications currently associated with the <i>DataReader</i> .	
	get_matched_publication_participant_data	Gets information on a DomainParticipant of a matching publication.	<a href="#">40.10.2 Finding the Matching Publication's ParticipantBuiltinTopicData on page 661</a>
	get_subscriber	Gets the <i>Subscriber</i> that created the <i>DataReader</i> .	<a href="#">40.10.3 Finding a DataReader's Related Entities on page 661</a>
	get_topicdescription	Gets the Topic associated with the <i>DataReader</i> .	
	is_matched_publication_alive	Enables you to query whether the matched <i>DataWriter</i> (using the instance handle returned by <b>get_matched_publications</b> ) is alive. <b>get_matched_publications</b> returns all matching <i>DataWriters</i> , including those that are not alive. This operation enables you to see which matching <i>DataWriters</i> are alive.	<a href="#">40.10.1 Finding Matching Publications on page 660</a>
Working with Conditions	create_query-condition	Creates a <i>QueryCondition</i> .	<a href="#">15.9.7 ReadConditions and QueryConditions on page 66</a>
	create_read-condition	Creates a <i>ReadCondition</i> .	
	delete_read-condition	Deletes a <i>ReadCondition/QueryCondition</i> attached to the <i>DataReader</i> .	
	delete_contained_entities	Deletes all the <i>ReadConditions/QueryConditions</i> that were created by means of the "create" operations on the <i>DataReader</i> .	<a href="#">40.3.1 Deleting Contained ReadConditions on page 622</a>
	get_statuscondition	Gets the StatusCondition associated with the Entity.	<a href="#">15.9.8 StatusConditions on page 69</a>
	create_read-condition_w_params	Creates a <i>ReadCondition</i> with parameters.	<a href="#">15.9.7 ReadConditions and QueryConditions on page 66</a>
	create_query-condition_w_params	Creates a <i>QueryCondition</i> with parameters.	<a href="#">15.9.7 ReadConditions and QueryConditions on page 66</a>

Table 40.1 DataReader Operations

Purpose	Operation	Description	Reference
Working with TopicQueries	create_topic_query	Creates a TopicQuery. The returned TopicQuery will have been issued if the <i>DataReader</i> is enabled. Otherwise, the TopicQuery will be issued once the DataReader is enabled.	<a href="#">Topic Queries (Chapter 60 on page 1142)</a>
	delete_topic_query	Deletes an active TopicQuery. After deleting a TopicQuery, new <i>DataWriters</i> won't discover it and existing <i>DataWriters</i> currently publishing cached samples may stop before delivering all of them.	
	lookup_topic_query	Retrieves the TopicQuery that corresponds to the input GUID. To get the GUID associated with a TopicQuery, use the TopicQuery's <code>get_guid()</code> .	
Waiting for Historical Data	wait_for_historical_data	Waits until all "historical" (previously sent) data is received. Only valid for Reliable <i>DataReaders</i> with non-VOLATILE DURABILITY.	<a href="#">40.6 Waiting for Historical Data on page 625</a>

## 40.1 Creating DataReaders

Before you can create a *DataReader*, you need a *DomainParticipant* and a *Topic*.

*DataReaders* are created by calling `create_datareader()` or `create_datareader_with_profile()`—these operations exist for *DomainParticipants* and *Subscribers*. If you use the *DomainParticipant* to create a *DataReader*, it will belong to the implicit *Subscriber* described in [39.1 Creating Subscribers Explicitly vs. Implicitly on page 600](#). If you use a *Subscriber's* operations to create a *DataReader*, it will belong to that *Subscriber*.

A QoS profile is way to use QoS settings from an XML file or string. With this approach, you can change QoS settings without recompiling the application. For details, see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

Note: In the Modern C++ API, *DataReaders* provide constructors whose first argument is a *Subscriber*. The only required arguments are the subscriber and the topic.

```

DDSDataReader* create_datareader (
    DDSTopicDescription *topic,
    const DDS_DataReaderQos &qos,
    DDSDataReaderListener *listener,
    DDS_StatusMask mask);
DDSDataReader * create_datareader_with_profile (
    DDSTopicDescription * topic,
    const char * library_name,
    const char * profile_name,
    DDSDataReaderListener * listener,
    DDS_StatusMask mask)

```

Where:

**topic**            The *Topic* to which the *DataReader* is subscribing. This must have been previously created by the same *DomainParticipant*.

<b>qos</b>	<p>If you want the default QoS settings (described in the API Reference HTML documentation), use <code>DDS_DATAREADER_QOS_DEFAULT</code> for this parameter (see <a href="#">Figure 40.1: Creating a DataReader with Default QoS Policies below</a>). If you want to customize any of the QoS Policies, supply a QoS structure (see <a href="#">40.9 Setting DataReader QoS Policies on page 652</a>).</p> <p><b>Note:</b> If you use <code>DDS_DATAREADER_QOS_DEFAULT</code> for the <code>qos</code> parameter, it is not safe to create the <i>DataReader</i> while another thread may be simultaneously calling the <i>Subscriber's set_default_datareader_qos()</i> operation.</p>
<b>listener</b>	<p>A <i>DataReader's Listener</i> is where you define the callback routine that will be notified when new DDS data samples arrive. <i>Connex</i> also uses this <i>Listener</i> to notify your application of specific events (status changes) that may occur with respect to the <i>DataReader</i>. For more information, see <a href="#">40.4 Setting Up DataReaderListeners on the next page</a> and <a href="#">40.7 Statuses for DataReaders on page 626</a>.</p> <p>The <i>listener</i> parameter is optional; you may use NULL instead. In that case, the <i>Subscriber's Listener</i> (or if that is NULL, the <i>DomainParticipant's Listener</i>) will receive the notifications instead. See <a href="#">40.4 Setting Up DataReaderListeners on the next page</a> for more on <i>DataReaderListeners</i>.</p>
<b>mask</b>	<p>This bit mask indicates which status changes will cause the <i>Listener</i> to be invoked. The bits set in the mask must have corresponding callbacks implemented in the <i>Listener</i>. If you use NULL for the <i>Listener</i>, use <code>DDS_STATUS_MASK_NONE</code> for this parameter. If the <i>Listener</i> implements all callbacks, use <code>DDS_STATUS_MASK_ALL</code>. For information on statuses, see <a href="#">15.8 Listeners on page 46</a>.</p>
<b>library_name</b>	<p>A QoS Library is a named set of QoS profiles. See <a href="#">50.2 QoS Profiles on page 906</a>.</p>
<b>profile_name</b>	<p>A QoS profile groups a set of related QoS, usually one per entity. See <a href="#">50.2 QoS Profiles on page 906</a>.</p>

After you create a *DataReader*, you can use it to retrieve received data. See [Chapter 41 Using DataReaders to Access Data \(Read & Take\) on page 663](#).

Note: When a *DataReader* is created, only those transports already registered are available to the *DataReader*. The built-in transports are implicitly registered when (a) the *DomainParticipant* is enabled, (b) the first *DataReader* is created, or (c) you lookup a built-in *DataReader*, whichever happens first.

[Figure 40.1: Creating a DataReader with Default QoS Policies below](#) shows an example of how to create a *DataReader* with default QoS Policies.

#### Figure 40.1: Creating a DataReader with Default QoS Policies

```
// MyReaderListener is user defined, extends DDSDataReaderListener
DDSDataReaderListener *reader_listener = new MyReaderListener();
DataReader* reader = subscriber->create_datareader(topic,
    DDS_DATAREADER_QOS_DEFAULT,
    reader_listener, DDS_STATUS_MASK_ALL);
if (reader == NULL) {
    // ... error
}
// narrow it into your specific data type
FooDataReader* foo_reader = FooDataReader::narrow(reader);
```

For more examples on how to create a *DataReader*, see [40.9.1 Configuring QoS Settings when the DataReader is Created on page 655](#).

## 40.2 Getting All DataReaders

To retrieve all the *DataReaders* created by the *Subscriber*, use the *Subscriber*'s `get_all_datareaders()` operation:

```
DDS_ReturnCode_t get_all_datareaders(
    DDS_Subscriber* self,
    struct DDS_DataReaderSeq* readers);
```

In the Modern C++ API, use the freestanding function `rti::sub::find_datareaders()`.

## 40.3 Deleting DataReaders

(Note: in the Modern C++ API, *Entities* are automatically destroyed, see [15.1 Creating and Deleting DDS Entities on page 33](#))

**To delete a *DataReader*:**

Delete any *ReadConditions* and *QueryConditions* that were created with the *DataReader*. Use the *DataReader*'s `delete_readcondition()` operation to delete them one at a time, or use the `delete_contained_entities()` operation ([40.3.1 Deleting Contained ReadConditions below](#)) to delete them all at the same time.

```
DDS_ReturnCode_t delete_readcondition (DDSReadCondition *condition)
```

Delete the *DataReader* by using the *Subscriber*'s `delete_datareader()` operation ([39.3 Deleting Subscribers on page 602](#)).

**Note:** A *DataReader* cannot be deleted within its own reader listener callback, see [15.8.8.1 Restricted Operations in Listener Callbacks on page 57](#).

To delete all of a *Subscriber*'s *DataReaders*, use the *Subscriber*'s `delete_contained_entities()` operation (see [39.3.1 Deleting Contained DataReaders on page 603](#)).

### 40.3.1 Deleting Contained ReadConditions

The *DataReader*'s `delete_contained_entities()` operation deletes all the *ReadConditions* and *QueryConditions* ([15.9.7 ReadConditions and QueryConditions on page 66](#)) that were created by the *DataReader*.

```
DDS_ReturnCode_t delete_contained_entities ()
```

After this operation returns successfully, the application may delete the *DataReader* (see [40.3 Deleting DataReaders above](#)).

## 40.4 Setting Up DataReaderListeners

*DataReaders* may optionally have *Listeners*. A *DataReaderListener* is a collection of callback methods; these methods are invoked by *Connex*t when DDS data samples are received or when there are status

changes for the *DataReader*.

**Note:** Some operations cannot be used within a listener callback, see [15.8.8.1 Restricted Operations in Listener Callbacks on page 57](#).

If you do not implement a *DataReaderListener*, the associated *Subscriber's Listener* is used instead. If that *Subscriber* does not have a *Listener* either, then the *DomainParticipant's Listener* is used if one exists (see [39.6 Setting Up SubscriberListeners on page 610](#) and [16.3.6 Setting Up DomainParticipantListeners on page 94](#)).

If you do not require asynchronous notification of data availability or status changes, you do not need to set a *Listener* for the *DataReader*. In that case, you will need to periodically call one of the **read()** or **take()** operations described in [Chapter 41 Using DataReaders to Access Data \(Read & Take\) on page 663](#) to access the data that has been received.

*Listeners* are typically set up when the *DataReader* is created (see [40.1 Creating DataReaders on page 620](#)). You can also set one up after creation by using the *DataReader's* **get\_listener()** and **set\_listener()** operations. *Connex* will invoke a *DataReader's Listener* to report the status changes listed in [Table 40.2 DataReaderListener Callbacks](#) (if the *Listener* is set up to handle the particular status, see [40.4 Setting Up DataReaderListeners on the previous page](#)).

**Table 40.2 DataReaderListener Callbacks**

This DataReaderListener callback...	...is triggered by a change in this status:
on_data_available()	<a href="#">40.7.1 DATA_AVAILABLE Status on page 627</a>
on_liveliness_changed()	<a href="#">40.7.4 LIVELINESS_CHANGED Status on page 634</a>
on_requested_deadline_missed()	<a href="#">40.7.5 REQUESTED_DEADLINE_MISSED Status on page 635</a>
on_requested_incompatible_qos()	<a href="#">40.7.6 REQUESTED_INCOMPATIBLE_QOS Status on page 636</a>
on_sample_lost()	<a href="#">40.7.7 SAMPLE_LOST Status on page 636</a>
on_sample_rejected()	<a href="#">40.7.8 SAMPLE_REJECTED Status on page 640</a>
on_subscription_matched()	<a href="#">40.7.9 SUBSCRIPTION_MATCHED Status on page 642</a>

Note that the same callbacks can be implemented in the *SubscriberListener* or *DomainParticipantListener* instead. There is only one *SubscriberListener* callback that takes precedence over a *DataReaderListener's*. An **on\_data\_on\_readers()** callback in the *SubscriberListener* (or *DomainParticipantListener*) takes precedence over the **on\_data\_available()** callback of a *DataReaderListener*.

If the *SubscriberListener* implements an **on\_data\_on\_readers()** callback, it will be invoked instead of the *DataReaderListener's* **on\_data\_available()** callback when new data arrives. The **on\_data\_on\_readers()** operation can in turn cause the **on\_data\_available()** method of the appropriate *DataReaderListener* to be invoked by calling the *Subscriber's* **notify\_datareaders()** operation. For more information on status and *Listeners*, see [15.8 Listeners on page 46](#).

**Figure 40.2: Simple DataReaderListener** below shows a *DataReaderListener* that simply prints the data it receives.

**Figure 40.2: Simple DataReaderListener**

```
class MyReaderListener : public DDSDataReaderListener {
public:
    virtual void on_data_available(DDSDataReader* reader);
    // don't do anything for the other callbacks
};
void MyReaderListener::on_data_available(DDSDataReader* reader)
{
    FooDataReader *Foo_reader = NULL;
    FooSeq data_seq; // In C, sequences have to be initialized
    DDS_SampleInfoSeq info_seq; // before use, see 41.5 The Sequence Data Structure on page 675
    DDS_ReturnCode_t retcode;
    int i;
    // Must cast generic reader into reader of specific type
    Foo_reader = FooDataReader::narrow(reader);
    if (Foo_reader == NULL) {
        printf("DataReader narrow error\n");
        return;
    }
    retcode = Foo_reader->take(data_seq, info_seq,
        DDS_LENGTH_UNLIMITED, DDS_ANY_SAMPLE_STATE,
        DDS_ANY_VIEW_STATE, DDS_ANY_INSTANCE_STATE);
    if (retcode == DDS_RETCODE_NO_DATA) {
        return;
    } else if (retcode != DDS_RETCODE_OK) {
        printf("take error %d\n", retcode);
        return;
    }
    for (i = 0; i < data_seq.length(); ++i) {
        // the data may not be valid if the DDS sample is
        // meta information about the creation or deletion
        // of an instance
        if (info_seq[i].valid_data) {
            FooTypeSupport::print_data(&data_seq[i]);
        }
    }
    // Connnext DDS gave a pointer to internal memory via
    // take(), must return the memory when finished processing the data
    retcode = Foo_reader->return_loan(data_seq, info_seq);
    if (retcode != DDS_RETCODE_OK) {
        printf("return loan error %d\n", retcode);
    }
}
```

## 40.5 Checking DataReader Status and StatusConditions

You can access individual communication status for a *DataReader* with the operations shown in [Table 1 DataReader Status Operations](#).

**Table 1 DataReader Status Operations**

Use this operation...	...to retrieve this status:
<code>get_datareader_cache_status</code>	<a href="#">40.7.2 DATA_READER_CACHE_STATUS on page 627</a>
<code>get_datareader_protocol_status</code>	<a href="#">40.7.3 DATA_READER_PROTOCOL_STATUS on page 630</a>
<code>get_matched_publication_datareader_protocol_status</code>	
<code>get_liveliness_changed_status</code>	<a href="#">40.7.4 LIVELINESS_CHANGED Status on page 634</a>
<code>get_sample_lost_status</code>	<a href="#">40.7.7 SAMPLE_LOST Status on page 636</a>
<code>get_sample_rejected_status</code>	<a href="#">40.7.8 SAMPLE_REJECTED Status on page 640</a>
<code>get_requested_deadline_missed_status</code>	<a href="#">40.7.5 REQUESTED_DEADLINE_MISSED Status on page 635</a>
<code>get_requested_incompatible_qos_status</code>	<a href="#">40.7.6 REQUESTED_INCOMPATIBLE_QOS Status on page 636</a>
<code>get_subscription_match_status</code>	<a href="#">40.7.9 SUBSCRIPTION_MATCHED Status on page 642</a>
<code>get_status_changes</code>	All of the above
<code>get_statuscondition</code>	See <a href="#">15.9.8 StatusConditions on page 69</a>

These methods are useful in the event that no *Listener* callback is set to receive notifications of status changes. If a *Listener* is used, the callback will contain the new status information, in which case calling these methods is unlikely to be necessary.

The `get_status_changes()` operation provides a list of statuses that have changed since the last time the status changes were ‘reset.’ A status change is reset each time the application calls the corresponding `get_*_status()`, as well as each time *Connex*t returns from calling the *Listener* callback associated with that status.

For more on status, see [40.4 Setting Up DataReaderListeners on page 622](#), [40.7 Statuses for DataReaders on the next page](#), and [15.8 Listeners on page 46](#).

## 40.6 Waiting for Historical Data

The `wait_for_historical_data()` operation waits (blocks) until all "historical" data is received from matched *DataWriters*. "Historical" data means DDS samples that were written before the *DataReader* joined the DDS domain.

This operation is intended only for *DataReaders* that have:

- [47.9 DURABILITY QosPolicy on page 809](#) **kind** set to *TRANSIENT\_LOCAL* (not *VOLATILE*)
- [47.21 RELIABILITY QosPolicy on page 845](#) **kind** set to *RELIABLE*

Calling `wait_for_historical_data()` on a non-reliable *DataReader* will always return immediately, since *Connex* will never deliver historical data to non-reliable *DataReaders*.

As soon as an application enables a non-VOLATILE *DataReader*, it will start receiving both "historical" data as well as any new data written by matching *DataWriters*. If you want the subscribing application to wait until all "historical" data is received, use this operation:

```
DDS_ReturnCode_t wait_for_historical_data (const DDS_Duration_t & max_wait)
```

The `wait_for_historical_data()` operation blocks the calling thread until either all "historical" data is received or the duration specified by the `max_wait` parameter elapses, whichever happens first. A return value of OK indicates that all the "historical" data was received; a return value of TIMEOUT indicates that `max_wait` elapsed before all the data was received.

`wait_for_historical_data()` will return immediately if no *DataWriters* have been discovered at the time the operation is called. Therefore it is advisable to make sure at least one *DataWriter* has been discovered before calling this operation; one way to do this is to use `get_subscription_matched_status()`, like this:

```
while (1) {
    DDS_SubscriptionMatchedStatus status;
    MyType_reader->get_subscription_matched_status(status);
    if (status.current_count > 0) { break; }
    NDDSUtility::sleep(sleep_period);
}
```

## 40.7 Statuses for DataReaders

There are several types of statuses available for a *DataReader*. You can use the `get*_status()` operations ([40.5 Checking DataReader Status and StatusConditions on page 624](#)) to access and reset them, use a *DataReaderListener* ([40.4 Setting Up DataReaderListeners on page 622](#)) to listen for changes in their values (for those statuses that have Listeners), or use a *StatusCondition* and a *WaitSet* ([15.9.8 StatusConditions on page 69](#)) to wait for changes. Each status has an associated data structure and is described in more detail in the following sections.

- [40.7.1 DATA\\_AVAILABLE Status on the next page](#)
- [40.7.2 DATA\\_READER\\_CACHE\\_STATUS on the next page](#)
- [40.7.3 DATA\\_READER\\_PROTOCOL\\_STATUS on page 630](#)
- [40.7.4 LIVELINESS\\_CHANGED Status on page 634](#)
- [40.7.5 REQUESTED\\_DEADLINE\\_MISSED Status on page 635](#)
- [40.7.6 REQUESTED\\_INCOMPATIBLE\\_QOS Status on page 636](#)
- [40.7.7 SAMPLE\\_LOST Status on page 636](#)

- [40.7.8 SAMPLE\\_REJECTED Status on page 640](#)
- [40.7.9 SUBSCRIPTION\\_MATCHED Status on page 642](#)

## 40.7.1 DATA\_AVAILABLE Status

This status indicates that new data is available for the *DataReader*. In most cases, this means that one new DDS sample has been received. However, there are situations in which more than one DDS samples for the *DataReader* may be received before the **DATA\_AVAILABLE** status changes. For example, if the *DataReader* has the [47.9 DURABILITY QosPolicy on page 809](#) set to be non-VOLATILE, then the *DataReader* may receive a batch of old DDS data samples all at once. Or if data is being received reliably from *DataWriters*, *Connex* may present several DDS samples of data simultaneously to the *DataReader* if they have been originally received out of order.

A change to this status also means that the **DATA\_ON\_READERS** status is changed for the *DataReader's Subscriber*. This status is reset when you call `read()`, `take()`, or one of their variations.

Unlike most other statuses, this status (as well as **DATA\_ON\_READERS** for *Subscribers*) is a *read communication status*. See [39.9 Statuses for Subscribers on page 613](#) and [15.7.1 Types of Communication Status on page 40](#) for more information on read communication statuses.

The *DataReaderListener's on\_data\_available()* callback is invoked when this status changes, unless the *SubscriberListener* ([39.6 Setting Up SubscriberListeners on page 610](#)) or *DomainParticipantListener* ([16.3.6 Setting Up DomainParticipantListeners on page 94](#)) has implemented an `on_data_on_readers()` callback. In that case, `on_data_on_readers()` will be invoked instead.

## 40.7.2 DATA\_READER\_CACHE\_STATUS

This status keeps track of the number of DDS samples and instances in the reader's cache, including the number of samples that were dropped for different reasons. For information on the instance states described in the reader's cache, such as "alive," "no\_writers," and "disposed," see [19.1 Instance States on page 258](#).

This status does not have an associated *Listener*. You can access this status by calling the *DataReader's get\_datareader\_cache\_status()* operation, which will return the status structure described in [Table 40.3 DDS\\_DataReaderCacheStatus](#).

**Table 40.3 DDS\_DataReaderCacheStatus**

Type	Field Name	Description
DDS_LongLong	sample_count_peak	Highest number of DDS samples in the <i>DataReader's</i> queue over the lifetime of the <i>DataReader</i> .
DDS_LongLong	sample_count	Current number of DDS samples in the <i>DataReader's</i> queue. Includes DDS samples that may not yet be available to be read or taken by the user due to DDS samples being received out of order or settings in the <a href="#">46.6 PRESENTATION QosPolicy on page 760</a> .

Table 40.3 DDS\_DataReaderCacheStatus

Type	Field Name	Description
DDS_ LongLong	writer_removed_batch_sample_ dropped_sample_count	<p>The number of batched samples received by the <i>DataReader</i> that were marked as removed by the <i>DataWriter</i>.</p> <p>When the <i>DataReader</i> receives a batch, the batch can contain samples marked as removed by the <i>DataWriter</i>. Examples of removed samples in a batch are samples that were replaced due to KEEP_LAST_HISTORY_QOS on the <i>DataWriter</i> (see <a href="#">47.12 HISTORY QoS Policy on page 818</a>) or samples that outlived the <i>DataWriter</i>'s <a href="#">47.14 LIFESPAN QoS Policy on page 824</a> duration. By default, any sample marked as removed from a batch is dropped, unless you set the <code>dds.data_reader.accept_writer_removed_batch_samples</code> property in the <a href="#">47.19 PROPERTY QoS Policy (DDS Extension) on page 837</a> to TRUE. (By default, it is set to FALSE.)</p> <p><b>Note:</b> Historical data with removed batch samples written before the <i>DataReader</i> joined the DDS domain are also included in the count.</p>
DDS_ LongLong	old_source_timestamp_dropped_ sample_count	<p>The number of samples dropped as a result of receiving a sample older than the last one, using DDS_BY_SOURCE_TIMESTAMP_DESTINATIONORDER_QOS.</p> <p>When the <i>DataReader</i> is using DDS_BY_SOURCE_TIMESTAMP_DESTINATIONORDER_QOS:</p> <ul style="list-style-type: none"> <li>• If the <i>DataReader</i> receives a sample for an instance with a source timestamp that is older than the last source timestamp received for the instance, the sample is dropped and included in this count.</li> <li>• If the <i>DataReader</i> receives a sample for an instance with a source timestamp that is equal to the last source timestamp received for the instance and the writer has a higher virtual GUID, the sample is dropped and included in this count.</li> </ul>
DDS_ LongLong	tolerance_source_timestamp_ dropped_sample_count	<p>The number of samples dropped as a result of receiving a sample in the future, using DDS_BY_SOURCE_TIMESTAMP_DESTINATIONORDER_QOS.</p> <p>When the <i>DataReader</i> is using DDS_BY_SOURCE_TIMESTAMP_DESTINATIONORDER_QOS, the <i>DataReader</i> will accept a sample only if the source timestamp is no farther in the future from the reception timestamp than the <code>source_timestamp_tolerance</code>. Otherwise, the sample is dropped and included in this count.</p>
DDS_ LongLong	ownership_dropped_sample_count	<p>The number of samples dropped as a result of receiving a sample from a <i>DataWriter</i> with a lower strength, using Exclusive Ownership.</p> <p>When using Exclusive Ownership, the <i>DataReader</i> receives data from multiple <i>DataWriters</i>. Each instance can only be owned by one <i>DataWriter</i>. If other <i>DataWriters</i> write samples belonging to this instance, the samples will be dropped.</p>
DDS_ LongLong	content_filter_dropped_sample_ count	<p>The number of samples filtered by the <i>DataReader</i> due to <i>ContentFilteredTopics</i>.</p> <p>When using a content filter on the <i>DataReader</i> side, if the sample received by the <i>DataReader</i> does not pass the filter, it will be dropped.</p>
DDS_ LongLong	time_based_filter_dropped_ sample_count	<p>The number of samples filtered by the <i>DataReader</i> due to the <a href="#">48.4 TIME_BASED_FILTER QoS Policy on page 888</a>.</p> <p>When using the <a href="#">48.4 TIME_BASED_FILTER QoS Policy on page 888</a> on the <i>DataReader</i> side, if the sample received by the <i>DataReader</i> does not pass the <code>minimum_separation</code> filter, it will be dropped.</p>

Table 40.3 DDS\_DataReaderCacheStatus

Type	Field Name	Description
DDS_ LongLong	expired_dropped_sample_count	<p>The number of samples expired by the <i>DataReader</i> due to the <a href="#">47.14 LIFESPAN QoS Policy on page 824</a> or the autopurge sample delays in the <a href="#">48.3 READER_DATA_LIFECYCLE QoS Policy on page 885</a>:</p> <ul style="list-style-type: none"> <li>• <b>DDS_LifespanQoSPolicy:</b> When a sample expires due to the <b>DDS_LifespanQoSPolicy</b>, the data is removed from the <i>DataReader</i> caches. This sample will be considered dropped if its <code>DDS_SampleStateKind</code> is <code>DDS_NOT_READ_SAMPLE_STATE</code>.</li> <li>• <b>DDS_ReaderDataLifecycleQoSPolicy::autopurge_nowriter_samples_delay:</b> When a sample expires due to the <b>autopurge_nowriter_samples_delay</b>, this sample will be considered dropped if its <code>DDS_SampleStateKind</code> is <code>DDS_NOT_READ_SAMPLE_STATE</code>.</li> <li>• <b>DDS_ReaderDataLifecycleQoSPolicy::autopurge_disposed_samples_delay:</b> When a sample expires due to the <b>autopurge_disposed_samples_delay</b>, this sample will be considered dropped if its <code>DDS_SampleStateKind</code> is <code>DDS_NOT_READ_SAMPLE_STATE</code>.</li> </ul>
DDS_ LongLong	virtual_duplicate_dropped_sample_count	<p>The number of virtual duplicate samples dropped by the <i>DataReader</i>. A sample is a virtual duplicate if it has the same identity (Virtual Writer GUID and Virtual Sequence Number) as a previously received sample.</p> <p>When two <i>DataWriters</i> with the same logical data source publish a sample with the same <b>sequence_number</b>, one sample will be dropped and the other will be received by the <i>DataReader</i>.</p> <p>This can happen when multiple writers are writing on behalf of the same original <i>DataWriter</i>: for example, in systems with redundant <i>RTI Routing Service</i> applications or when a <i>DataReader</i> is receiving samples both directly from the original <i>DataWriter</i> and from an instance of <i>RTI Persistence Service</i>.</p>
DDS_ LongLong	replaced_dropped_sample_count	<p>The number of samples replaced by the <i>DataReader</i> due to <code>DDS_KEEP_LAST_HISTORY_QOS</code> replacement in the <a href="#">47.12 HISTORY QoS Policy on page 818</a>.</p> <p>When the number of samples for an instance in the queue reaches the <b>depth</b> value in the <code>HISTORY QoSPolicy</code>, a new sample for the instance will replace the oldest sample for the instance in the queue. The new sample will be accepted, and the old sample will be dropped.</p> <p>This counter will only be updated if the replaced sample's <code>DDS_SampleStateKind</code> is <code>DDS_NOT_READ_SAMPLE_STATE</code>.</p>
DDS_ LongLong	total_samples_dropped_by_instance_replacement	Number of samples of the state <code>NOT_READ_SAMPLE_STATE</code> that were dropped when removing an instance due to instance replacement via the <b>instance_replacement</b> field in the <a href="#">48.2 DATA_READER_RESOURCE_LIMITS QoS Policy (DDS Extension) on page 876</a> .
DDS_ LongLong	alive_instance_count	Number of instances currently in the <i>DataReader's</i> queue that have an <b>instance_state</b> of <code>ALIVE</code> .
DDS_ LongLong	alive_instance_count_peak	Highest number of <code>ALIVE</code> instances in the <i>DataReader's</i> queue over the lifetime of the <i>DataReader</i> .
DDS_ LongLong	no_writers_instance_count	Number of instances in the <i>DataReader's</i> queue that have an <b>instance_state</b> of <code>NOT_ALIVE_NO_WRITERS</code> .
DDS_ LongLong	no_writers_instance_count_peak	Highest number of <code>NOT_ALIVE_NO_WRITERS</code> instances in the <i>DataReader's</i> queue over the lifetime of the <i>DataReader</i> .
DDS_ LongLong	disposed_instance_count	Number of instances in the <i>DataReader's</i> queue that have an <b>instance_state</b> of <code>NOT_ALIVE_DISPOSED</code> .
DDS_ LongLong	disposed_instance_count_peak	Highest number of <code>NOT_ALIVE_DISPOSED</code> instances in the <i>DataReader's</i> queue over the lifetime of the <i>DataReader</i> .

Table 40.3 DDS\_DataReaderCacheStatus

Type	Field Name	Description
DDS_ LongLong	detached_instance_count	Number of detached instances—which contain only the minimum instance state—currently being maintained in the <i>DataReader's</i> queue.  If <b>keep_minimum_state_for_instances</b> in the <a href="#">48.2 DATA_READER_RESOURCE_LIMITS QoSPolicy (DDS Extension) on page 876</a> is true (by default, it is), the <i>DataReader</i> will keep up to <b>max_total_instances</b> (in the DATA_READER_RESOURCE_LIMITS QoSPolicy) of detached instances in its queue. See <a href="#">40.8.7 Active State and Minimum State on page 649</a> for more information.
DDS_ LongLong	detached_instance_count_peak	Highest number of detached instances in the <i>DataReader's</i> queue over the lifetime of the <i>DataReader</i> .

### 40.7.3 DATA\_READER\_PROTOCOL\_STATUS

The status of a *DataReader's* internal protocol related metrics (such as the number of DDS samples received, filtered, rejected) and the status of wire protocol traffic. The structure for this status appears in [Table 40.4 DDS\\_DataReaderProtocolStatus](#).

This status does not have an associated Listener. You can access this status by calling the following operations on the *DataReader* (which return the status structure described in [Table 40.4 DDS\\_DataReaderProtocolStatus](#)):

**get\_datareader\_protocol\_status()** returns the sum of the protocol status for all the matched publications for the *DataReader*.

**get\_matched\_publication\_datareader\_protocol\_status()** returns the protocol status of a particular matched publication, identified by a **publication\_handle**.

The **get\_\*\_status()** operations also reset the related status so it is no longer considered “changed.”

**Note:** Status/data for a matched publication is kept even if the *DataWriter* is not alive (that is, has lost liveliness based on the [47.15 LIVELINESS QoSPolicy on page 825](#)). The status/data will be removed only if the *DataWriter* is gone: that is, the *DataWriter* is destroyed and this change is propagated through a discovery update, or the *DataWriter's DomainParticipant* is gone (either gracefully or its liveliness expired and *Connex* is configured to purge not-alive participants). Once a matched *DataWriter* is gone, its status is deleted. If you try to get the status/data for a matched publication that is gone, the 'get status' or 'get data' call will return an error.

The *DataReader's* protocol status includes information about DATA\_FRAG messages (sample fragments) if you are using DDS-level fragmentation. See [34.3 Large Data Fragmentation on page 524](#) for more information.

Table 40.4 DDS\_DataReaderProtocolStatus

Type	Field Name	Description
DDS_LongLong	received_sample_count	The number of samples received by a <i>DataReader</i> . <b>Note:</b> When data is fragmented, this count is updated when all of the fragments required to reassemble a sample are received, not when individual fragments are received. The fragment count is tracked in the <a href="#">received_fragment_count</a> .
	received_sample_count_change	Change in the <b>received_sample_count</b> since the last time the status was read.
	received_sample_bytes	The number of bytes received by a <i>DataReader</i> . <b>Note:</b> When data is fragmented, this statistic is updated upon the receipt of each fragment, not when a sample is reassembled.
	received_sample_bytes_change	Change in <b>received_sample_bytes</b> since the last time the status was read.
DDS_LongLong	duplicate_sample_count	The number of DDS samples received from a <i>DataWriter</i> , not for the first time, by this <i>DataReader</i> .
	duplicate_sample_count_change	Change in <b>duplicate_sample_count</b> since the last time the status was read.
	duplicate_sample_bytes	The number of bytes of DDS samples received from a <i>DataWriter</i> received, not for the first time, by this <i>DataReader</i> .
	duplicate_sample_bytes_change	Change in the <b>duplicate_sample_bytes</b> since the last time the status was read.
DDS_LongLong	DEPRECATED filtered_sample_count	The number of DDS samples filtered by this <i>DataReader</i> due to ContentFilteredTopics or Time-Based Filter.
	DEPRECATED filtered_sample_count_change	Change in the <b>filtered_sample_count</b> since the last time the status was read.
	DEPRECATED filtered_sample_bytes	The number of bytes of DDS samples filtered by this <i>DataReader</i> due to ContentFilteredTopics or Time-Based Filter.
	DEPRECATED filtered_sample_bytes_change	Change in the <b>filtered_sample_bytes</b> since the last time the status was read.

Table 40.4 DDS\_DataReaderProtocolStatus

Type	Field Name	Description
DDS_LongLong	received_heartbeat_count	The number of Heartbeats received from a <i>DataWriter</i> by this <i>DataReader</i> .
	received_heartbeat_count_change	Change in the <b>received_heartbeat_count</b> since the last time the status was read.
	received_heartbeat_bytes	The number of bytes of Heartbeats received from a <i>DataWriter</i> by this <i>DataReader</i> .
	received_heartbeat_bytes_change	Change in the <b>received_heartbeat_bytes</b> since the last time the status was read.
DDS_LongLong	sent_ack_count	The number of ACKs sent from this <i>DataReader</i> to a matching <i>DataWriter</i> .
	sent_ack_count_change	Change in the <b>sent_ack_count</b> since the last time the status was read.
	sent_ack_bytes	The number of bytes of ACKs sent from this <i>DataReader</i> to a matching <i>DataWriter</i> .
	sent_ack_bytes_change	Change in the <b>sent_ack_bytes</b> since the last time the status was read.
DDS_LongLong	sent_nack_count	The number of NACKs sent from this <i>DataReader</i> to a matching <i>DataWriter</i> .
	sent_nack_count_change	Change in the <b>sent_nack_count</b> since the last time the status was read.
	sent_nack_bytes	The number of bytes of NACKs sent from this <i>DataReader</i> to a matching <i>DataWriter</i> .
	sent_nack_bytes_change	Change in the <b>sent_nack_bytes</b> since the last time the status was read.
DDS_LongLong	received_gap_count	The number of GAPS received from a <i>DataWriter</i> to this <i>DataReader</i> .
	received_gap_count_change	Change in the <b>received_gap_count</b> since the last time the status was read.
	received_gap_bytes	The number of bytes of GAPS received from a <i>DataWriter</i> to this <i>DataReader</i> .
	received_gap_bytes_change	Change in the <b>received_gap_bytes</b> since the last time the status was read.

Table 40.4 DDS\_DataReaderProtocolStatus

Type	Field Name	Description
DDS_LongLong	rejected_sample_count	<p>The number of times a sample is rejected because it cannot be accepted by a reliable <i>DataReader</i>. Samples rejected by a reliable <i>DataReader</i> will be NACKed, and they will have to be resent by the <i>DataWriter</i> if they are still available in the <i>DataWriter</i> queue.</p> <p><b>Note:</b> This count is a subset of the <b>total_count</b> in the <a href="#">40.7.8 SAMPLE_REJECTED Status on page 640</a>. The <b>total_count</b> in the <b>SAMPLE_REJECTED</b> status includes both protocol-related rejections, that trigger a repair or resend (the <b>rejected_sample_count</b> described here), and the rejections described in the <a href="#">40.7.8 SAMPLE_REJECTED Status on page 640</a>. For example, the <b>DDS_REJECTED_BY_SAMPLES_PER_INSTANCE_LIMIT</b> in the <b>SAMPLE_REJECTED</b> status is not part of the <b>rejected_sample_count</b> because it does not trigger a repair or resend.</p>
	rejected_sample_count_change	Change in the <b>rejected_sample_count</b> since the last time the status was read.
DDS_LongLong	out_of_range_rejected_sample_count	<p>The number of samples dropped by the <i>DataReader</i> due to the receive window being full and the sample received out-of-order.</p> <p>When using reliable <a href="#">47.21 RELIABILITY QosPolicy on page 845</a>, if the <i>DataReader</i> receives samples out-of-order, they are stored internally until the missing samples are received. The number of out-of-order samples that the <i>DataReader</i> can keep is set by the <b>receive_window_size</b> in the <a href="#">Table 48.2 DDS_RtpsReliableReaderProtocol_t on page 873</a>. When the receive window is full, any out-of-order sample received will be dropped and included in this count (but not in the <b>SampleRejectedStatus</b>).</p>
DDS_SequenceNumber_t	first_available_sample_sequence_number	Sequence number of the first available DDS sample in a matched <i>DataWriter's</i> reliability queue. Applicable only when retrieving matched <i>DataWriter</i> statuses.
	last_available_sample_sequence_number	Sequence number of the last available DDS sample in a matched <i>DataWriter's</i> reliability queue. Applicable only when retrieving matched <i>DataWriter</i> statuses.
	last_committed_sample_sequence_number	<p>Sequence number of the last committed DDS sample (i.e. available to be read or taken) in a matched <i>DataWriter's</i> reliability queue. Applicable only when retrieving matched <i>DataWriter</i> statuses.</p> <p>For best-effort <i>DataReaders</i>, this is the sequence number of the latest DDS sample received.</p> <p>For reliable <i>DataReaders</i>, this is the sequence number of the latest DDS sample that is available to be read or taken from the <i>DataReader's</i> queue.</p>
DDS_Long	uncommitted_sample_count	Number of received DDS samples that are not yet available to be read or taken due to being received out of order. Applicable only when retrieving matched <i>DataWriter</i> statuses.
DDS_LongLong	received_fragment_count	The number of fragments (DATA_FRAG messages) that have been received by this <i>DataReader</i> . This count is incremented upon the receipt of each DATA_FRAG message. Fragments from duplicate samples do not count towards this number. Applicable only when data is fragmented.
DDS_LongLong	dropped_fragment_count	The number of DATA_FRAG messages that have been dropped by the <i>DataReader</i> . This count does not include malformed fragments. Applicable only when data is fragmented.
DDS_LongLong	reassembled_sample_count	The number of samples that have been reassembled by the <i>DataReader</i> . This statistic is incremented when all of the fragments that are required to reassemble an entire sample have been received. Applicable only when data is fragmented.

Table 40.4 DDS\_DataReaderProtocolStatus

Type	Field Name	Description
DDS_LongLong	sent_nack_fragment_count	The number of NACK FRAG RTPS messages that have been sent from the <i>DataReader</i> to a <i>DataWriter</i> . NACK FRAG RTPS messages are sent when large data is used in conjunction with reliable communication. They have the same properties as NACK messages, but instead of applying to samples, they apply to fragments. Applicable only when data is fragmented.
	sent_nack_fragment_bytes	The number of NACK FRAG RTPS message bytes that have been sent from the <i>DataReader</i> to a <i>DataWriter</i> . NACK FRAG RTPS messages are sent when large data is used in conjunction with reliable communication. They have the same properties as NACK messages, but instead of applying to samples, they apply to fragments. Applicable only when data is fragmented.

## 40.7.4 LIVELINESS\_CHANGED Status

This status indicates that the liveliness of one or more matched *DataWriters* has changed (i.e., one or more *DataWriters* has become alive or not alive). The mechanics of determining liveliness between a *DataWriter* and a *DataReader* is specified in their [47.15 LIVELINESS QosPolicy on page 825](#).

The structure for this status appears in [Table 40.5 DDS\\_LivelinessChangedStatus](#).

Table 40.5 DDS\_LivelinessChangedStatus

Type	Field Name	Description
DDS_Long	alive_count	Number of matched <i>DataWriters</i> that are currently alive.
	not_alive_count	Number of matched <i>DataWriters</i> that are not currently alive.
	alive_count_change	The change in the <b>alive_count</b> since the last time the <i>Listener</i> was called or the status was read.
	not_alive_count_change	The change in the <b>not_alive_count</b> since the last time the <i>Listener</i> was called or the status was read. Note that a positive <b>not_alive_count_change</b> means one of the following: <ul style="list-style-type: none"> <li>The <i>DomainParticipant</i> containing the matched <i>DataWriter</i> has lost liveliness or has been deleted.</li> <li>The matched <i>DataWriter</i> has lost liveliness or has been deleted.</li> </ul>
DDS_InstanceHandle_t	last_publication_handle	This InstanceHandle can be used to look up which remote <i>DataWriter</i> was the last to cause this <i>DataReader's</i> status to change, using the <i>DataReader's</i> <b>get_matched_publication_data()</b> method. It's possible that the <i>DataWriter</i> has been purged from the discovery database. If so, <b>get_matched_publication_data()</b> will not be able to return information about the <i>DataWriter</i> . In this case, the only way to get information about the lost <i>DataWriter</i> is if you cached the information previously.

The *DataReaderListener's* **on\_liveliness\_changed()** callback may be called for the following reasons:

- The liveliness of any *DataWriter* matching this *DataReader* (as defined by the [47.15 LIVELINESS QosPolicy on page 825](#)) is lost.
- A *DataWriter's* liveliness is recovered after being lost.

- A new matching *DataWriter* has been discovered.
- A QoS Policy has changed such that a *DataWriter* that matched this *DataReader* before no longer matches (such as a change to the PartitionQoSPolicy). In this case, *Connex* will no longer keep track of the *DataWriter*'s liveliness. Furthermore:
  - If the *DataWriter* was alive when it and the *DataReader* stopped matching: **alive\_count** will decrease (since there's one less matching alive *DataWriter*) and **not\_alive\_count** will remain the same (since the *DataWriter* is still alive).
  - If the *DataWriter* was not alive when it and the *DataReader* stopped matching: **alive\_count** will remain the same (since the matching *DataWriter* was not alive) and **not\_alive\_count** will decrease (since there's one less not-alive matching *DataWriter*).

**Note:** There are several ways that a *DataWriter* and *DataReader* can become incompatible after the *DataWriter* has lost liveliness. For example, when the [47.15 LIVELINESS QoSPolicy on page 825](#) kind is set to `MANUAL_BY_PARTICIPANT_LIVELINESS_QOS`, it is possible that the *DataWriter* has not asserted its liveliness in a timely manner, and then a QoS change occurs on the *DataWriter* or *DataReader* that makes the entities incompatible.

- A QoS Policy (such as the PartitionQoSPolicy) has changed such that a *DataWriter* that was unmatched with the *DataReader* now matches.

You can also retrieve the value by calling the *DataReader*'s `get_liveliness_changed_status()` operation; this will also reset the status so it is no longer considered "changed."

This status is reciprocal to the [31.6.9 RELIABLE\\_READER\\_ACTIVITY\\_CHANGED Status \(DDS Extension\) on page 408](#) for a *DataWriter*.

## 40.7.5 REQUESTED\_DEADLINE\_MISSED Status

This status indicates that the *DataReader* did not receive a new DDS sample for an data-instance within the time period set in the *DataReader*'s [47.7 DEADLINE QoSPolicy on page 804](#). For non-keyed Topics, this simply means that the *DataReader* did not receive data within the DEADLINE period. For keyed Topics, this means that for one of the data-instances that the *DataReader* was receiving, it has not received a new DDS sample within the DEADLINE period. For more information about keys and instances, see [Chapter 8 DDS Samples, Instances, and Keys on page 17](#).

The structure for this status appears in [Table 40.6 DDS\\_RequestedDeadlineMissedStatus](#).

**Table 40.6 DDS\_RequestedDeadlineMissedStatus**

Type	Field Name	Description
DDS_Long	total_count	Cumulative number of times that the deadline was violated for any instance read by the <i>DataReader</i> .
	total_count_change	The change in total_count since the last time the <i>Listener</i> was called or the status was read.
DDS_InstanceHandle_t	last_instance_handle	Handle to the last data-instance in the <i>DataReader</i> for which a requested deadline was missed.

The *DataReaderListener*'s **on\_requested\_deadline\_missed()** callback is invoked when this status changes. You can also retrieve the value by calling the *DataReader*'s **get\_requested\_deadline\_missed\_status()** operation; this will also reset the status so it is no longer considered “changed.”

## 40.7.6 REQUESTED\_INCOMPATIBLE\_QOS Status

A change to this status indicates that the *DataReader* discovered a *DataWriter* for the same *Topic*, but that *DataReader* had requested QoS settings incompatible with this *DataWriter*'s offered QoS.

The structure for this status appears in [Table 40.7 DDS\\_RequestedIncompatibleQosStatus](#) .

**Table 40.7 DDS\_RequestedIncompatibleQosStatus**

Type	Field Name	Description
DDS_Long	total_count	Cumulative number of times the <i>DataReader</i> discovered a <i>DataWriter</i> for the same <i>Topic</i> with an offered QoS that is incompatible with that requested by the <i>DataReader</i> .
DDS_Long	total_count_change	The change in total_count since the last time the <i>Listener</i> was called or the status was read.
DDS_QosPolicyId_t	last_policy_id	The ID of the QosPolicy that was found to be incompatible the last time an incompatibility was detected. (Note: if there are multiple incompatible policies, only one of them is reported here.)
DDS_QosPolicyCountSeq	policies	A list containing—for each policy—the total number of times that the <i>DataReader</i> discovered a <i>DataWriter</i> for the same <i>Topic</i> with a offered QoS that is incompatible with that requested by the <i>DataReader</i> .

The *DataReaderListener*'s **on\_requested\_incompatible\_qos()** callback is invoked when this status changes. You can also retrieve the value by calling the *DataReader*'s **get\_requested\_incompatible\_qos\_status()** operation; this will also reset the status so it is no longer considered “changed.”

## 40.7.7 SAMPLE\_LOST Status

This status indicates that one or more DDS samples written by a matched *DataWriter* have failed to be received and will never be received.

Some samples written by a *DataWriter* to its matching *DataReaders* may never be received by the *DataReaders*. This can happen because something went wrong while trying to add the sample to the

*DataReader's* queue, like a decryption or deserialization error, or because the sample was removed from the *DataWriter's* queue before it was received by the *DataReaders*. A sample can be removed from the *DataWriter's* queue before it is delivered to matching *DataReaders* for a number of reasons, including that *DataWriters* are limited in the number of published DDS data samples that they can store, so that if a *DataWriter* continues to publish DDS data samples, new data may overwrite old data that has not yet been received by the *DataReader*. The DDS samples that are overwritten can never be resent to the *DataReader* and thus are considered to be *lost*. *DataWriters* may also set the [47.14 LIFESPAN QoS Policy on page 824](#), and samples that expire due to lifespan may also be reported as lost by a *DataReader* that has not received those samples.

The *lost* status applies to reliable *and* best-effort *DataReaders*, see the [47.21 RELIABILITY QoS Policy on page 845](#). By reporting a sample as lost, the *DataReader* has declared that the sample will never be received, and will therefore not NACK it. It cannot be repaired by a *DataWriter* or resent to the *DataReader*.

Before a sample is received by a *DataReader* it may also be reported as rejected or dropped. (See [40.7.8 SAMPLE\\_REJECTED Status on page 640](#) and [40.7.2 DATA\\_READER\\_CACHE\\_STATUS on page 627](#).)

The structure for the *lost* status appears in [Table 40.8 DDS\\_SampleLostStatus](#).

**Table 40.8 DDS\_SampleLostStatus**

Type	Field Name	Description
DDS_Long	total_count	Cumulative count of all the DDS samples that have been lost, across all instances of data written for the <i>Topic</i> .
	total_count_change	The incremental number of DDS samples lost since the last time the <i>Listener</i> was called or the status was read.
DDS_SampleLostStatusKind	last_reason	The reason the last DDS sample was lost. See <a href="#">Table 40.9 DDS_SampleLostStatusKind</a> .

The reason the DDS sample was lost appears in the **last\_reason** field. The possible values are listed in [Table 40.9 DDS\\_SampleLostStatusKind](#).

**Table 40.9 DDS\_SampleLostStatusKind**

Reason Kind	Description
NOT_LOST	The sample was not lost.
LOST_BY_AVAILABILITY_WAITING_TIME	<b>max_data_availability_waiting_time</b> in the <a href="#">47.1 AVAILABILITY QoS Policy (DDS Extension) on page 769</a> expired.

Table 40.9 DDS\_SampleLostStatusKind

Reason Kind	Description
LOST_BY_DECODE_FAILURE	<p>When using BEST_EFFORT in the <a href="#">47.21 RELIABILITY QosPolicy on page 845</a>, a sample was lost because it could not be decoded.</p> <p>When using RELIABLE in the RELIABILITY QosPolicy, the sample is rejected, not lost, with the reason REJECTED_BY_DECODE_FAILURE.</p>
LOST_BY_DESERIALIZATION_FAILURE	<p>A sample was lost because it could not be deserialized. A sample may fail to be deserialized for the following reasons:</p> <ul style="list-style-type: none"> <li>• The subscribing application has received a sample with a sequence or string member that is longer than the maximum allowed by the <i>DataReader's</i> data type.</li> <li>• The subscribing application has received a sample with an unknown enum value. See the description of the <code>dds.sample_assignability.accept_unknown_enum_value</code> property in the <a href="#">Property Reference Guide</a> for more information.</li> <li>• The subscribing application has received a sample with an unknown union discriminator value. See the description of the <code>dds.sample_assignability.accept_unknown_union_discriminator</code> property in the <a href="#">Property Reference Guide</a> for more information.</li> <li>• The subscribing application has received a sample with an out-of-range value for one of the members that has been configured with a minimum or maximum value using the min, max, or range type annotations.</li> <li>• Sample corruption has occurred. If this is the case, then using <i>RTI Security Plugins</i> or enabling CRC (see the <code>compute_crc</code> and <code>check_crc</code> fields in the <a href="#">44.9 WIRE_PROTOCOL QosPolicy (DDS Extension) on page 730</a>) can help avoid these failures.</li> </ul>
LOST_BY_INCOMPLETE_COHERENT_SET	<p>A sample was lost because it is part of an incomplete coherent set. An incomplete coherent set is a coherent set for which some of the samples are missing.</p> <p>For example, consider a <i>DataWriter</i> using KEEP_LAST in the <a href="#">47.12 HISTORY QosPolicy on page 818</a> with a <b>depth</b> of 1. The <i>DataWriter</i> publishes two samples of the same instance as part of a coherent set "CS1"; the first sample of "CS1" is replaced by a new sample before it can be successfully delivered to the <i>DataReader</i>. In this case, the coherent set containing the two samples is considered incomplete. The new sample, by default, will not be provided to the application, and will be reported as LOST_BY_INCOMPLETE_COHERENT_SET. (You can change this default behavior by setting <code>drop_incomplete_coherent_set</code> to FALSE in the <a href="#">46.6 PRESENTATION QosPolicy on page 760</a>. If you do, the new sample will be provided to the application, but it will be marked as part of an incomplete coherent set in the <a href="#">41.6 The SampleInfo Structure on page 676</a>.)</p>
LOST_BY_INSTANCES_LIMIT	<p><code>max_instances</code> in the <a href="#">47.22 RESOURCE_LIMITS QosPolicy on page 850</a> was reached.</p>
LOST_BY_LARGE_COHERENT_SET	<p>A sample was lost because it was part of a large coherent set. A large coherent set is a coherent set that cannot fit all at once into the <i>DataReader</i> queue because resource limits are exceeded.</p> <p>For example, if <code>max_samples_per_instance</code> on the <i>DataReader</i> is 10 and the coherent set has 15 samples for a given instance, the coherent set is a large coherent set that will be considered incomplete.</p> <p>The resource limits that can lead to large coherent sets are: <code>max_samples</code>, <code>max_samples_per_instance</code>, <code>max_instances</code>, and <code>max_samples_per_remote_writer</code>.</p>
LOST_BY_OUT_OF_MEMORY	<p>A sample was lost because there was not enough memory to store the sample.</p>
LOST_BY_REMOTE_WRITER_SAMPLES_PER_VIRTUAL_QUEUE_LIMIT	<p>A resource limit on the number of samples published by a <i>DataWriter</i> on behalf of a virtual <i>DataWriter</i> that a <i>DataReader</i> may store was reached. (This field is currently not used.)</p>
LOST_BY_REMOTE_WRITERS_PER_INSTANCE_LIMIT	<p><code>max_remote_writers_per_instance</code> in the <a href="#">48.2 DATA_READER_RESOURCE_LIMITS QosPolicy (DDS Extension) on page 876</a> was reached. (This limit is the number of <i>DataWriters</i> for a single instance from which a <i>DataReader</i> may read.)</p>
LOST_BY_REMOTE_WRITERS_PER_SAMPLE_LIMIT	<p><code>max_remote_writers_per_sample</code> in the <a href="#">47.22 RESOURCE_LIMITS QosPolicy on page 850</a> was reached. (This limit is the number of <i>DataWriters</i> that are allowed to write the same sample.)</p>

Table 40.9 DDS\_SampleLostStatusKind

Reason Kind	Description
LOST_BY_SAMPLES_LIMIT	<p>When using BEST_EFFORT in the <a href="#">47.21 RELIABILITY QosPolicy on page 845</a>, <b>max_samples</b> in the <a href="#">47.22 RESOURCE_LIMITS QosPolicy on page 850</a> was reached.</p> <p>When using RELIABLE in the RELIABILITY QosPolicy, reaching <b>max_samples</b> triggers a rejection, not a loss, with the reason REJECTED_BY_SAMPLES_LIMIT.</p>
LOST_BY_SAMPLES_PER_INSTANCE_LIMIT	<p>When using BEST_EFFORT in the <a href="#">47.21 RELIABILITY QosPolicy on page 845</a>, <b>max_samples_per_instance</b> in the <a href="#">47.22 RESOURCE_LIMITS QosPolicy on page 850</a> was reached.</p> <p>When using RELIABLE in the RELIABILITY QosPolicy, reaching <b>max_samples_per_instance</b> triggers a rejection, not a loss, with the reason REJECTED_BY_SAMPLES_PER_INSTANCE_LIMIT.</p>
LOST_BY_SAMPLES_PER_REMOTE_WRITER_LIMIT	<p>When using BEST_EFFORT in the <a href="#">47.21 RELIABILITY QosPolicy on page 845</a>, <b>max_samples_per_remote_writer</b> in the <a href="#">48.2 DATA_READER_RESOURCE_LIMITS QosPolicy (DDS Extension) on page 876</a> was reached. (This limit is the number of samples from a given <i>DataWriter</i> that a <i>DataReader</i> may store.)</p> <p>When using RELIABLE in the RELIABILITY QosPolicy, reaching <b>max_samples_per_remote_writer</b> triggers a rejection, not a loss, with the reason REJECTED_BY_SAMPLES_PER_REMOTE_WRITER_LIMIT.</p>
LOST_BY_UNKNOWN_INSTANCE	<p>A sample was lost because it didn't contain enough information for the <i>DataReader</i> to know what instance it was associated with.</p>

Table 40.9 DDS\_SampleLostStatusKind

Reason Kind	Description
LOST_BY_VIRTUAL_WRITERS_LIMIT	<p><b>max_remote_virtual_writers</b> in the <a href="#">48.2 DATA_READER_RESOURCE_LIMITS QoS Policy (DDS Extension) on page 876</a> was reached. (This limit is the number of virtual <i>DataWriters</i> from which a <i>DataReader</i> may read.)</p>
LOST_BY_WRITER	<p>A <i>DataWriter</i> removed the DDS sample before being received by the <i>DataReader</i>. The <i>DataReader</i> detects that a sample is lost:</p> <ul style="list-style-type: none"> <li>• For Best Effort <a href="#">47.21 RELIABILITY QoS Policy on page 845</a>: once a sample with a higher sequence number is received.</li> <li>• For Reliable RELIABILITY QoS Policy: once a heartbeat message is received that announces that a sample that the <i>DataReader</i> was waiting for is no longer available in the <i>DataWriter</i>'s queue (i.e., the first sequence number in the heartbeat is higher than the missing sample's sequence number). Samples that are gapped through GAP messages are not considered lost.</li> </ul> <p>Samples may be lost for any of the following reasons:</p> <ul style="list-style-type: none"> <li>• The lifespan of a sample expired before it was received by a <i>DataReader</i>; see <a href="#">47.14 LIFESPAN QoS Policy on page 824</a>.</li> <li>• For Best Effort RELIABILITY QoS Policy: a sample was lost on the network or arrived out of order at the <i>DataReader</i>. (For example, the <i>DataReader</i> received sample 2 but not sample 1; the <i>DataReader</i> considers sample 1 LOST_BY_WRITER.)</li> <li>• For Reliable RELIABILITY QoS Policy: <ul style="list-style-type: none"> <li>• When using KEEP_LAST <a href="#">47.12 HISTORY QoS Policy on page 818</a>, unacknowledged samples can be overwritten if the history <b>depth</b> limit is reached for an instance. <b>Important:</b> Depending on timing, samples that were replaced due to KEEP_LAST replacement may be gapped by a GAP message and are therefore not reported as lost by the <i>DataReader</i>, or, at other times, the heartbeat message will announce that the sample is no longer available, as described above, and these will be reported as lost.</li> <li>• For KEEP_ALL HISTORY QoS Policy, the <i>DataWriter</i> can overwrite a sample in its queue after the <i>DataReader</i> was marked as 'inactive'. Once a <i>DataReader</i> is marked as 'inactive', samples will no longer be considered unacknowledged by that <i>DataReader</i> until it becomes active again. This means that if resource limits are hit and space is needed for a new sample, an old sample may be replaced to make room even if the inactive <i>DataReader</i> never received it. A <i>DataReader</i> is considered inactive either because it is not making progress (see <a href="#">inactivate_nonprogressing_readers</a>) or <a href="#">max_heartbeat_retries</a> was exceeded.</li> </ul> </li> </ul> <p>See <a href="#">32.4.2 Tuning Queue Sizes and Other Resource Limits on page 454</a> for more information on changing sample loss or queue configuration.</p>

The *DataReaderListener*'s **on\_sample\_lost()** callback is invoked when this status changes. You can also retrieve the value by calling the *DataReader*'s **get\_sample\_lost\_status()** operation; this will also reset the status so it is no longer considered "changed."

## 40.7.8 SAMPLE\_REJECTED Status

This status indicates that one or more DDS samples received from a matched *DataWriter* have been rejected by the *DataReader* because a resource limit would have been exceeded: for example, if the receive queue is full because the number of DDS samples in the queue is equal to the **max\_samples** parameter of the [47.22 RESOURCE\\_LIMITS QoS Policy on page 850](#). These rejected samples could be

accepted later once the conditions for acceptance are met (e.g., once the number of samples in the queue becomes less than **max\_samples**). A sample that is rejected can be resent any number of times until it is eventually reported as lost, dropped, or accepted.

Samples can be rejected only with reliable communication; see [47.21 RELIABILITY QosPolicy on page 845](#). In best-effort communication, samples cannot be rejected because samples cannot be received again and are not eligible for resending.

The structure for the *rejected* status appears in [Table 40.10 DDS\\_SampleRejectedStatus](#). The reason the DDS sample was rejected appears in the **last\_reason** field. The possible values are listed in [Table 40.11 DDS\\_SampleRejectedStatusKind](#).

**Table 40.10 DDS\_SampleRejectedStatus**

Type	Field Name	Description
DDS_Long	total_count	Cumulative count of all the DDS samples that have been rejected by the <i>DataReader</i> .
	total_count_change	The incremental number of DDS samples rejected since the last time the <i>Listener</i> was called or the status was read.
	current_count	The current number of writers with which the <i>DataReader</i> is matched.
	current_count_change	The change in <b>current_count</b> since the last time the <i>Listener</i> was called or the status was read.
DDS_SampleRejectedStatusKind	last_reason	Reason for rejecting the last DDS sample. See <a href="#">Table 40.11 DDS_SampleRejectedStatusKind</a> .
DDS_InstanceHandle_t	last_instance_handle	Handle to the data-instance for which the last DDS sample was rejected.

**Table 40.11 DDS\_SampleRejectedStatusKind**

Reason Kind	Description
DDS_NOT_REJECTED	DDS sample was accepted.
REJECTED_BY_DECODE_FAILURE	When using RELIABLE in the <a href="#">47.21 RELIABILITY QosPolicy on page 845</a> , a sample was rejected because it could not be decoded. When using BEST_EFFORT in the <a href="#">47.21 RELIABILITY QosPolicy on page 845</a> , the sample is lost, not rejected, with the reason LOST_BY_DECODE_FAILURE.
DDS_REJECTED_BY_INSTANCES_LIMIT	This field is not currently used.
DDS_REJECTED_BY_SAMPLES_LIMIT	When using RELIABLE in the <a href="#">47.21 RELIABILITY QosPolicy on page 845</a> , <b>max_samples</b> in the <a href="#">47.22 RESOURCE_LIMITS QosPolicy on page 850</a> was reached. When using BEST_EFFORT in the RELIABILITY QosPolicy, reaching <b>max_samples</b> triggers a loss, not a rejection, with the reason LOST_BY_SAMPLES_LIMIT.

Table 40.11 DDS\_SampleRejectedStatusKind

Reason Kind	Description
DDS_REJECTED_BY_SAMPLES_PER_INSTANCE_LIMIT	When using RELIABLE in the <a href="#">47.21 RELIABILITY QoS Policy on page 845</a> , <b>max_samples_per_instance</b> in the <a href="#">47.22 RESOURCE_LIMITS QoS Policy on page 850</a> was reached. When using BEST_EFFORT in the RELIABILITY QoS Policy, reaching <b>max_samples_per_instance</b> triggers a loss, not a rejection, with the reason LOST_BY_SAMPLES_PER_INSTANCE_LIMIT.
DDS_REJECTED_BY_SAMPLES_PER_REMOTE_WRITER_LIMIT	When using RELIABLE in the <a href="#">47.21 RELIABILITY QoS Policy on page 845</a> , <b>max_samples_per_remote_writer</b> in the <a href="#">48.2 DATA_READER_RESOURCE_LIMITS QoS Policy (DDS Extension) on page 876</a> was reached. (This limit is the number of samples that a <i>DataReader</i> may store from a specific <i>DataWriter</i> .) When using BEST_EFFORT in the RELIABILITY QoS Policy, reaching <b>max_samples_per_remote_writer</b> triggers a loss, not a rejection, with the reason LOST_BY_SAMPLES_PER_REMOTE_WRITER_LIMIT.
DDS_REJECTED_BY_REMOTE_WRITER_SAMPLES_PER_VIRTUAL_QUEUE_LIMIT	This field is currently not used.

The *DataReaderListener*'s **on\_sample\_rejected()** callback is invoked when this status changes. You can also retrieve the value by calling the *DataReader*'s **get\_sample\_rejected\_status()** operation; this will also reset the status so it is no longer considered “changed.”

## 40.7.9 SUBSCRIPTION\_MATCHED Status

A change to this status indicates that the *DataReader* discovered a matching *DataWriter*. A ‘match’ occurs only if the *DataReader* and *DataWriter* have the same *Topic*, same or compatible data type, and compatible QoS Policies. (For more information on compatible data types, see the [RTI Connex Core Libraries Extensible Types Guide](#).) In addition, if user code has directed *Connex* to ignore certain *DataWriters*, then those *DataWriters* will never be matched. See [27.2 Ignoring Publications and Subscriptions on page 354](#) for more on setting up a *DomainParticipant* to ignore specific *DataWriters*.

This status is also changed (and the listener, if any, called) when a match is ended. A *DataReader* will become unmatched from a *DataWriter* when that *DataWriter* goes away for any of the following reasons:

- The *DomainParticipant* containing the matched *DataWriter* has lost liveliness.
- The *DataReader* or the matched *DataWriter* has changed QoS such that the entities are now incompatible.
- The matched *DataWriter* has been deleted.

This status may reflect changes from multiple match or unmatched events, and the **current\_count\_change** can be used to determine the number of changes since the listener was called back or the status was checked.

The structure for this status appears in [Table 40.12 DDS\\_SubscriptionMatchedStatus](#).

Table 40.12 DDS\_SubscriptionMatchedStatus

Type	Field Name	Description
DDS_Long	total_count	Cumulative number of times the <i>DataReader</i> discovered a "match" with a <i>DataWriter</i> . This number increases whenever a new match is discovered. It does not decrease when an existing match goes away for any of the reasons listed above.
	total_count_change	The changes in <b>total_count</b> since the last time the listener was called or the status was read. Note that this number will never be negative (because it's the total number of times the <i>DataReader</i> ever matched with a <i>DataWriter</i> ).
	current_count	The number of <i>DataWriters</i> currently matched to the concerned <i>DataReader</i> . This number increases when a new match is discovered and decreases when an existing match goes away for any of the reasons listed above.
	current_count_change	The change in <b>current_count</b> since the last time the listener was called or the status was read. Note that a negative <b>current_count_change</b> means that one or more <i>DataWriters</i> have become unmatched for one or more of the reasons listed above.
	current_count_peak	Greatest number of <i>DataWriters</i> that matched this <i>DataReader</i> simultaneously. That is, there was no moment in time when more than this many <i>DataWriters</i> matched this <i>DataReader</i> . (As a result, <b>total_count</b> can be higher than <b>current_count_peak</b> .)
DDS_InstanceHandle_t	last_publication_handle	This InstanceHandle can be used to look up which remote <i>DataWriter</i> was the last to cause this <i>DataReader</i> 's status to change, using the <i>DataReader</i> 's <b>get_matched_publication_data()</b> method. If the <i>DataWriter</i> no longer matches this <i>DataReader</i> due to any of the reasons listed above except incompatible QoS, then the <i>DataWriter</i> has been purged from this <i>DataReader</i> 's <i>DomainParticipant</i> discovery database. (See <a href="#">Chapter 22 Discovery Overview on page 309</a> .) In that case, the <i>DataReader</i> 's <b>get_matched_publication_data</b> method will not be able to return information about the <i>DataWriter</i> . The only way to get information about the lost <i>DataWriter</i> is if you cached the information previously.

The *DataReaderListener*'s **on\_subscription\_matched()** callback is invoked when this status changes. You can also retrieve the value by calling the *DataReader*'s **get\_subscription\_match\_status()** operation; this will also reset the status so it is no longer considered "changed."

## 40.8 Accessing and Managing Instances (Working with Keyed Data Types)

This section describes how instances work on *DataReaders*. This section applies only to data types that use keys; see [Chapter 8 DDS Samples, Instances, and Keys on page 17](#). See also [Chapter 19 Working with Instances on page 257](#).

A *DataReader* receives updates about instances and instance state changes as `DATA_AVAILABLE` statuses, the same way it receives data updates. (See [40.7.1 DATA\\_AVAILABLE Status on page 627](#).) *DataReaders* can access instance state as part of the **SampleInfo** that is returned when calling any variant of **read()** or **take()** (such as **read\_instance()** or **take\_instance()**).

## 40.8.1 Instance States

As seen in [Figure 40.3: Instance States on the next page](#), *Connex* keeps an **instance\_state** for each instance:

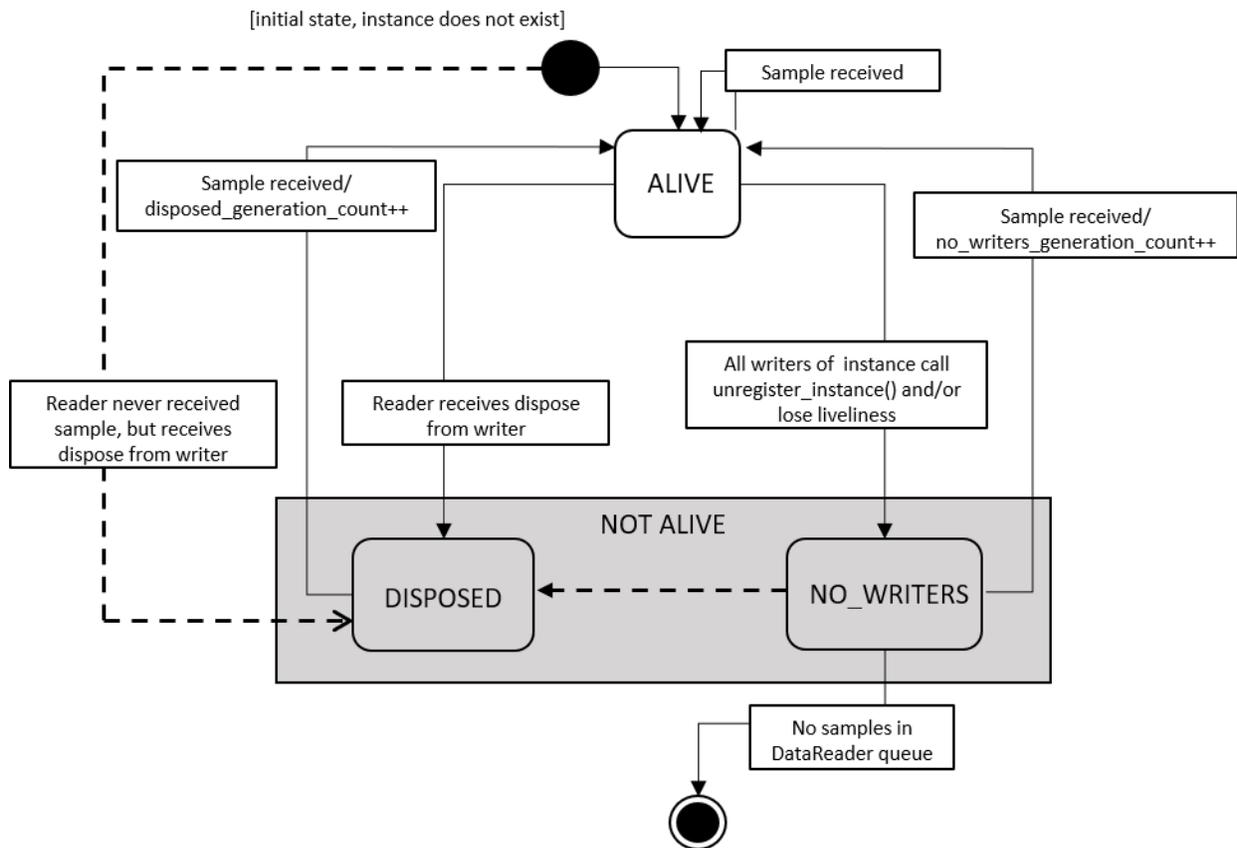

- **ALIVE**: The following are all true: (a) DDS samples have been received for the instance, (b) there are live *DataWriters* writing the instance, and (c) the instance has not been explicitly disposed (or more DDS samples have been received after it was disposed).
- **NOT\_ALIVE\_DISPOSED**: The instance was explicitly disposed by a *DataWriter* by means of the **dispose()** operation, or implicitly as a result of the **autodispose\_unregistered\_instances** QoS setting.
- **NOT\_ALIVE\_NO\_WRITERS**: The instance has been declared as not-alive by the *DataReader* because it has determined that there are no live *DataWriter* entities that have previously written the instance.

Instances can cycle through these phases as seen in the state diagram below, becoming **NOT\_ALIVE** and then becoming **ALIVE** again. To track these transitions, there is metadata the *DataReader* can query called generation counts. (See [40.8.2 Generation Counts and Ranks on page 646](#).)

The events that cause the **instance\_state** to change can depend on the setting of the [47.17 OWNERSHIP QoS Policy on page 833](#):

- If OWNERSHIP QoS is set to **EXCLUSIVE**, the **instance\_state** becomes **NOT\_ALIVE\_DISPOSED** only if the *DataWriter* that currently “owns” the instance explicitly disposes it. The **instance\_state** will become **ALIVE** again only if the *DataWriter* that owns the instance writes it. Note that ownership of the instance is determined by a combination of the OWNERSHIP QoS Policy and [47.18 OWNERSHIP\\_STRENGTH QoS Policy on page 836](#). Ownership of an instance can dynamically change.
- If OWNERSHIP QoS is set to **SHARED**, the **instance\_state** becomes **NOT\_ALIVE\_DISPOSED** if any *DataWriter* explicitly disposes the instance. The **instance\_state** becomes **ALIVE** as soon as any *DataWriter* writes the instance again.

Figure 40.3: Instance States

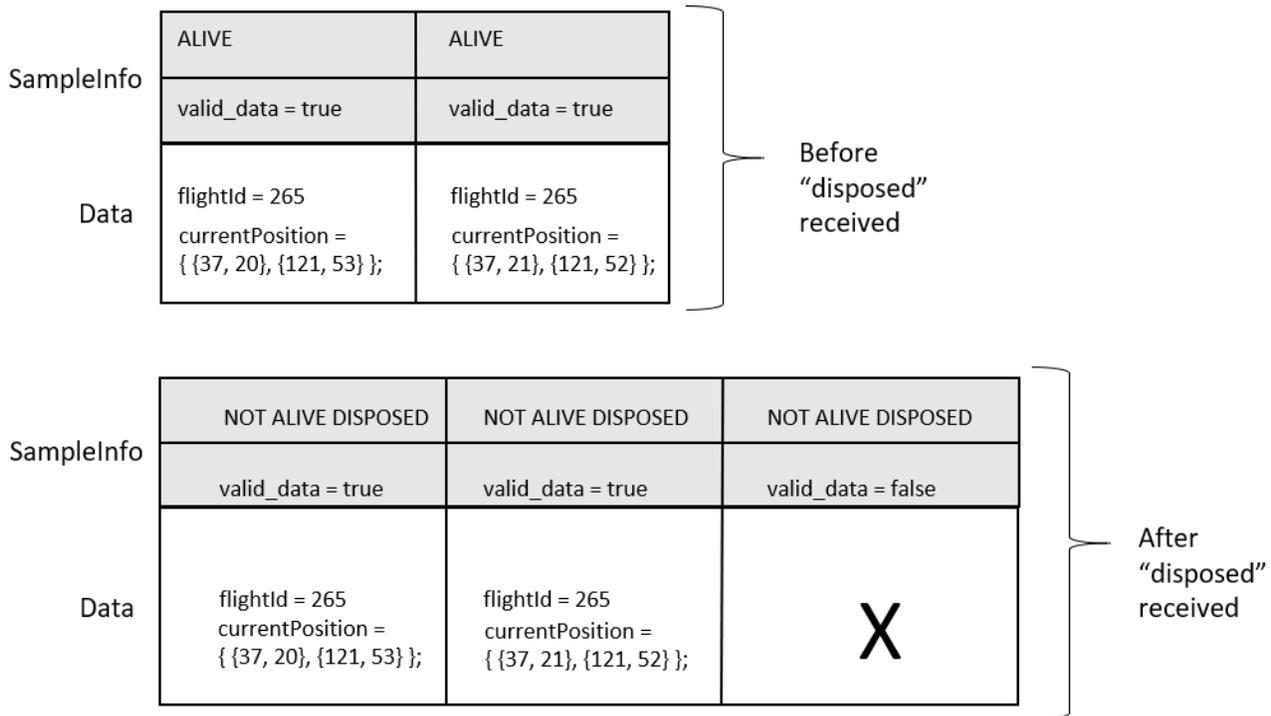

*Transitions shown with dashes are only available if `propagate_dispose_of_unregistered_instances = true`*

Since the **instance\_state** in the **SampleInfo** structure is a per-instance concept, all DDS data samples related to the same instance that are returned by **read()** or **take()** will have the same value for **instance\_state**. This means that if there are samples for that instance in the *DataReader's* queue that were received when the instance was **ALIVE**, and a subsequent dispose message is received, the samples' metadata will indicate that the instance's state is **NOT\_ALIVE\_DISPOSED** in all of them.

**Note:** The **instance\_state** always reflects the current state of the instance at the time of reading.

Figure 40.4: Before and After Dispose Received

When the dispose message is received (the box with the X, with `valid_data = false`), all samples for the flight 265 instance in the queue are marked as `NOT_ALIVE_DISPOSED`, even those that contain live data from when the instance was `ALIVE`.

**Note:** If an instance transitions its state to `NOT_ALIVE_NO_WRITERS` due to one or more `DataWriters` losing liveness, it will not transition back to `ALIVE` if the `DataWriter` regains liveness. It only returns to the `ALIVE` state if a `DataWriter` writes a new sample of the instance.

## 40.8.2 Generation Counts and Ranks

Generation counts and ranks allow your application to distinguish DDS samples belonging to different 'generations' of the instance. It is possible for an instance to become alive, be disposed and become not-alive, and then cycle again from alive to not-alive states during the operation of an application. Each time an instance becomes alive defines a new generation for the instance.

It is possible that an instance may cycle through alive and not-alive states multiple times before the application accesses the DDS data samples for the instance. This means that the DDS data samples returned by `read()` and `take()` may cross generations. That is, some DDS samples were published when the instance was alive in one generation and other DDS samples were published when the instance transitioned through the non-alive state into the alive state again. It may be important to your application to distinguish the DDS data samples by the generation in which they were published.

Each *DataReader* keeps two counters for each instance it detects (recall that instances are distinguished by their key values):

- **disposed\_generation\_count**: Counts how many times the **instance\_state** of the corresponding instance changes from **NOT\_ALIVE\_DISPOSED** to **ALIVE**.
- **no\_writers\_generation\_count**: Counts how many times the **instance\_state** of the corresponding instance changes from **NOT\_ALIVE\_NO\_WRITERS** to **ALIVE**.

The **disposed\_generation\_count** and **no\_writers\_generation\_count** fields in the **SampleInfo** structure capture a snapshot of the corresponding counters at the time the corresponding DDS sample was received.

The **sample\_rank** and **generation\_rank** in the **SampleInfo** structure are computed relative to the sequence of DDS samples returned by **read()** or **take()**:

- **sample\_rank**: Indicates how many DDS samples of the same instance follow the current one in the sequence. The DDS samples are always time-ordered, thus the newest DDS sample of an instance will have a **sample\_rank** of 0. Depending on what you have configured **read()** and **take()** to return (by passing in state masks and through the **max\_samples\_per\_read** field in [48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QoS Policy \(DDS Extension\) on page 876](#)), a **sample\_rank** of 0 may or may not be the newest DDS sample that was ever received. It is just the newest DDS sample in the sequence that was returned. The **sample\_rank** value could be used by an application to determine that there are newer samples in the sequence and that it might want to skip processing the older samples.
- **generation\_rank**: Indicates the difference in ‘generations’ between the DDS sample and the newest DDS sample of the same instance as returned in the sequence. If a DDS sample belongs to the same generation as the newest DDS sample in the sequence returned by **read()** and **take()**, then **generation\_rank** will be 0.
- **absolute\_generation\_rank**: Indicates the difference in ‘generations’ between the DDS sample and the newest DDS sample of the same instance ever received by the *DataReader*. Recall that the data sequence returned by **read()** and **take()** may not contain all of the data in the *DataReader*’s receive queue. Thus, a DDS sample that belongs to the newest generation of the instance will have an **absolute\_generation\_rank** of 0.

By using the **sample\_rank**, **generation\_rank** and **absolute\_generation\_rank** information in the **SampleInfo** structure, your application can determine exactly what happened to the instance and thus make appropriate decisions of what to do with the DDS data samples received for the instance. For example:

- A DDS sample with **sample\_rank=0** is the newest DDS sample of the instance in the returned sequence.

- DDS samples that belong to the same generation will have the same **generation\_rank** (as well as **absolute\_generation\_rank**).
- DDS samples with **absolute\_generation\_rank** = 0 belong to the newest generation for the instance received by the *DataReader*.

The ‘generation count’ and ‘rank’ values are statistics that are locally generated by each *DataReader* and maintained as part of the metadata for the instance that they refer to. Therefore, if the instance is reclaimed and then returns at a later point in time, these counters will all restart at 0.

### 40.8.3 Valid Data Flag

The **SampleInfo** structure’s **valid\_data** flag indicates whether the DDS sample contains data or is only used to communicate a change in the **instance\_state** of the instance.

Normally, each DDS sample contains both a **SampleInfo** structure and some data. However, there are situations in which the DDS sample only contains the **SampleInfo** and does not have any associated data. This occurs when *Connex* notifies the application of a change of state for an instance for which there is no associated data. An example is when *Connex* detects that an instance has no writers and changes the corresponding **instance\_state** to NOT\_ALIVE\_NO\_WRITERS.

If the **valid\_data** flag is TRUE, then the DDS sample contains valid data. If the flag is FALSE, the DDS sample contains no data.

To ensure correctness and portability, your application must check the **valid\_data** flag prior to accessing the data associated with the DDS sample, and only access the data if it is TRUE. The value of data is undefined when the **valid\_data** flag is false.

### 40.8.4 Looking up an Instance Handle

Some operations, such as **read\_instance()**, require an **instance\_handle** parameter. If you need to get such a handle, you can call the *FooDataReader*’s **lookup\_instance()** operation, which takes a sample with key fields specified as a parameter and returns a handle to that instance.

```
DDS_InstanceHandle_t lookup_instance (const Foo & key_holder)
```

The instance must have been received by the *DataReader* in order for the *DataReader* to look it up. If the instance is not known to the *DataReader*, this operation returns **DDS\_HANDLE\_NIL**.

### 40.8.5 Getting the Key Value for an Instance

Once you have an instance handle (using **lookup\_instance()**, as part of a status change notification, or through the **SampleInfo**), you can use the *DataReader*’s **get\_key\_value()** operation to retrieve the value of the key of the corresponding instance. The key fields of the data structure passed into **get\_key\_value()** will be filled out with the original values used to generate the instance handle. The key

fields are defined when the data type is defined; see [Chapter 8 DDS Samples, Instances, and Keys on page 17](#) for more information.

If you set `propagate_dispose_of_unregistered_instances` to true and wish to call `get_key_value()` for instances for which only a dispose sample has been received, the `serialize_key_with_dispose` field in the [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 788](#) must be set to true.

## 40.8.6 Instance Resource Limits and Memory Management

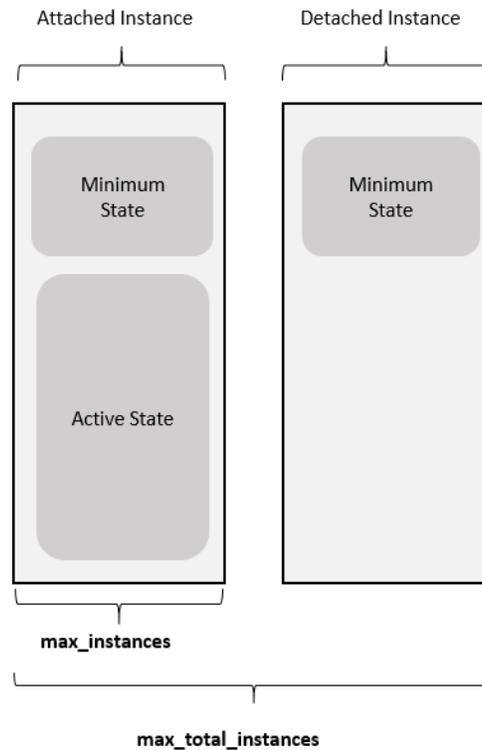

In *Connex*, memory is primarily pre-allocated when creating entities. When data is keyed, the memory associated with each instance used for storing instance-specific metadata is allocated when the *DataReader* is created. Memory is not freed at runtime, unless you delete an entity. Instead, memory is made available to be reused by the *DataReader*, or “reclaimed”.

The *DataReader* can receive a number of instances defined by the [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#) and [48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 876](#). It is also important to understand that an instance in the *DataReader* queue has two parts that make up the instance metadata: an active state and a minimum state. The resource limits control the amount of active state and minimum state that should be maintained. (Note: the concept of active and minimum state does not apply to instance metadata in the *DataWriter* queue.)

### 40.8.7 Active State and Minimum State

An instance is considered either *attached* or *detached* in the *DataReader* queue and is composed of two parts, which make up the instance metadata: an active state and a minimum state.

Figure 40.5: Active and Minimum Instance States

An instance is considered *attached* when the *DataReader* is actively managing all possible state that can be associated with an instance, including the associated samples, the instance and view states, generation and sample ranks, the list of remote writers that are known to be writing the instance, and so on. Only attached instances can have associated samples. A *DataReader* keeps both the active and the minimum state for attached instances. The sum of the **alive\_instance\_count**, **disposed\_instance\_count**, and **no\_writers\_instance\_count** statistics in the [40.7.2 DATA\\_READER\\_CACHE\\_STATUS](#) on [page 627](#) reflects the total number of attached instances currently in the *DataReader* queue.

The following is applicable only if **keep\_minimum\_state\_for\_instances** in the [48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QoS Policy \(DDS Extension\)](#) on [page 876](#) is TRUE (by default, it is). See [48.2.2 keep\\_minimum\\_state\\_for\\_instances](#) on [page 882](#) for more on this QoS setting.

An instance is considered *detached* when the *DataReader* is only maintaining the minimum state for the instance. When instances are replaced or purged from the *DataReader* queue, by default only the active state of the instance is reclaimed. A minimum amount of state for the instance is kept even after the instance is removed in order to maintain system consistency without having to waste resources (memory and CPU) by keeping other information around that is no longer relevant (i.e., the active state). The minimum state is used when instances that have been removed re-enter the system. This can happen, for example, when a non-VOLATILE *DataReader* and *DataWriter* lose liveliness and then re-discover each other. The *DataWriter* will resend its history, but if the *DataReader* has the minimum state information for any instances that it removed during the disconnection, the previously received

duplicate samples will be filtered out and dropped before being accepted into the *DataReader's* queue again. The minimum state includes information such as the last source timestamp, the keyhash, and the list of virtual writers for the instance. In general, you should keep **keep\_minimum\_state\_for\_instances** set to true if you are using the Durable Reader State, MultiChannel *DataWriters*, or *RTI Persistence Service*, or in any system where instances may be removed and then re-enter the system either because the original *DataWriter* is re-discovered or writes the instance again or a new *DataWriter* begins writing the instance.

An instance transitions from what is considered an *attached* instance to a *detached* instance when the instance is removed from the *DataReader* queue (purged or replaced). This can happen under the following conditions:

- The instance is replaced due to the **instance\_replacement** settings in the [48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 876](#).
- There are no more samples associated with the instance. Samples can be removed from the *DataReader* queue through the use of the **take()** operation, or various QoS configurations such as a finite lifespan or KEEP\_LAST history configuration. In addition, at least one of the following must be true:
  - The instance was in the NOT\_ALIVE\_NO\_WRITERS instance state and **autopurge\_nowriter\_instances\_delay** has expired. (The default value for the **autopurge\_nowriter\_instances\_delay** is 0, so by default instances are purged as soon as the instance is empty and transitions to NOT\_ALIVE\_NO\_WRITERS.)
  - The instance was in the NOT\_ALIVE\_DISPOSED instance state and the **autopurge\_disposed\_instances\_delay** has expired.

The **detached\_instance\_count** statistic in the [40.7.2 DATA\\_READER\\_CACHE\\_STATUS on page 627](#) counts the total number of detached instances currently in the *DataReader* queue.

## 40.8.8 Instance Resource Limit QoS Policies

The [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#) and [48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 876](#) include the following fields that affect the number of instances that can be received:

- **max\_instances** ([47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#)): A resource limit on the number of attached instances that can be managed by *Connex*. By default, **max\_instances** is UNLIMITED, so you are bounded only by the physical resources of your system. If the **max\_instances** limit has been hit, and a sample is received for a new instance, *Connex* will first attempt to replace an instance according to what you have configured in the **instance\_replacement** field in the [48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 876](#). If there are not any replaceable instances (by default empty NOT\_ALIVE\_DISPOSED

and `NOT_ALIVE_NO_WRITERS` instances are replaceable, and `ALIVE` instances are not replaceable), the sample will be lost with the reason `LOST_BY_INSTANCES_LIMIT`, and not re-sent by the *DataWriter*. The sum of the `alive_instance_count`, `disposed_instance_count`, and `no_writers_instance_count` statistics in the [40.7.2 DATA\\_READER\\_CACHE\\_STATUS on page 627](#) reflects the total number of attached instances currently in the *DataReader* queue.

- **max\_total\_instances** ([48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QoS Policy \(DDS Extension\) on page 876](#)): A resource limit on the combined total number of attached+detached instances that can be managed by *Connex*. This resource limit limits the number of minimum instance states that can be kept by the middleware, and both attached and detached instances require the minimum instance state to be kept. The `detached_instance_count` statistic in the [40.7.2 DATA\\_READER\\_CACHE\\_STATUS on page 627](#) counts the total number of detached instances currently in the *DataReader* queue.
  - When a *DataReader* receives a new instance, *Connex* will check `max_instances`. If `max_instances` is not exceeded, *Connex* will check `max_total_instances`. If `max_total_instances` is exceeded, *Connex* will replace one of the detached instances with the new, attached one. The application could receive duplicate samples for the replaced instance if it becomes alive again.
  - `max_total_instances` should be equal to the number of attached instances you want to keep, plus the number of detached instances you want to keep.
- **keep\_minimum\_state\_for\_instances** ([48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QoS Policy \(DDS Extension\) on page 876](#)): This QoS setting can be used to enable or disable *Connex* from keeping minimum instance information for detached instances. By default, this setting is `TRUE`. This minimum instance information is useful for the features described earlier in this section. If this QoS setting is `FALSE`, minimum instance state will not be kept, and therefore detached instances will not be kept.

The `instance_replacement` field in the [48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QoS Policy \(DDS Extension\) on page 876](#) controls whether instances can be replaced to make room for new ones. See [48.2.3 Configuring DataReader Instance Replacement on page 882](#).

The [48.3 READER\\_DATA\\_LIFECYCLE QoS Policy on page 885](#) controls whether the *DataReader* can remove data from the queue if instance state becomes `NOT_ALIVE_NO_WRITERS` or `NOT_ALIVE_DISPOSED`.

## 40.9 Setting DataReader QoS Policies

A *DataReader*'s QoS Policies control its behavior. Think of QoS Policies as the 'properties' of a *DataReader*.

The `DDS_DataReaderQos` structure has the following format:

```

DDS_DataWriterQos struct {
    DDS_DurabilityQosPolicy      durability;
    DDS_DeadlineQosPolicy        deadline;
    DDS_LatencyBudgetQosPolicy   latency_budget;
    DDS_LivelinessQosPolicy      liveliness;
    DDS_ReliabilityQosPolicy      reliability;
    DDS_DestinationOrderQosPolicy destination_order;
    DDS_HistoryQosPolicy          history;
    DDS_ResourceLimitsQosPolicy   resource_limits;
    DDS_UserDataQosPolicy         user_data;
    DDS_OwnershipQosPolicy        ownership;
    DDS_TimeBasedFilterQosPolicy  time_based_filter;
    DDS_ReaderDataLifecycleQosPolicy reader_data_lifecycle;
    DDS_DataRepresentationQosPolicy representation;
    DDS_TypeConsistencyEnforcementQosPolicy type_consistency;
    DDS_DataTagQosPolicy          data_tags;
    // extensions to the DDS standard:
    DDS_DataReaderResourceLimitsQosPolicy reader_resource_limits;
    DDS_DataReaderProtocolQosPolicy  protocol;
    DDS_TransportSelectionQosPolicy   transport_selection;
    DDS_TransportUnicastQosPolicy     unicast;
    DDS_TransportMulticastQosPolicy   multicast;
    DDS_PropertyQosPolicy            property;
    DDS_ServiceQosPolicy             service;
    DDS_AvailabilityQosPolicy         availability;
    DDS_EntityNameQosPolicy          subscription_name;
    DDS_TransportPriorityQosPolicy     transport_priority;
    DDS_TypeSupportQosPolicy         type_support;
} DDS_DataReaderQos;

```

**Note:** `set_qos()` cannot always be used within a listener callback, see [15.8.8.1 Restricted Operations in Listener Callbacks on page 57](#).

[Table 40.13 DataReader QosPolicies](#) summarizes the meaning of each policy. (They appear alphabetically in the table.) For information on *why* you would want to change a particular QosPolicy, see the referenced section. For defaults and valid ranges, please refer to the API Reference HTML documentation.

Table 40.13 DataReader QoS Policies

QoS Policy	Description
Availability	<p>This QoS policy is used in the context of two features:</p> <ul style="list-style-type: none"> <li>For a Collaborative DataWriter, specifies the group of DataWriters expected to collaboratively provide data and the timeouts that control when to allow data to be available that may skip DDS samples.</li> <li>For a Durable Subscription, configures a set of Durable Subscriptions on a DataWriter.</li> </ul> <p>See <a href="#">47.1 AVAILABILITY QoS Policy (DDS Extension) on page 769</a>.</p>
DataReaderProtocol	<p>This QoS Policy configures the DDS on-the-network protocol, RTPS. See <a href="#">48.1 DATA_READER_PROTOCOL QoS Policy (DDS Extension) on page 871</a>.</p>
DataReaderResourceLimits	<p>Various settings that configure how <i>DataReaders</i> allocate and use physical memory for internal resources. See <a href="#">48.2 DATA_READER_RESOURCE_LIMITS QoS Policy (DDS Extension) on page 876</a>.</p>
DataRepresentation	<p>Specifies which versions of the Extended Common Data Representation (CDR) are requested. See <a href="#">47.3 DATA_REPRESENTATION QoS Policy on page 780</a>.</p>
DataTag	<p>A sequence of (name, value) string pairs that may be used by the Access Control plugin. See <a href="#">47.4 DATATAG QoS Policy on page 787</a>.</p>
Deadline	<p>For a <i>DataReader</i>, it specifies the maximum expected elapsed time between arriving DDS data samples. For a <i>DataWriter</i>, it specifies a commitment to publish DDS samples with no greater elapsed time between them. See <a href="#">47.7 DEADLINE QoS Policy on page 804</a>.</p>
DestinationOrder	<p>Controls how <i>Connex</i>t will deal with data sent by multiple <i>DataWriters</i> for the same topic. Can be set to "by reception timestamp" or to "by source timestamp". See <a href="#">47.8 DESTINATION_ORDER QoS Policy on page 806</a>.</p>
Durability	<p>Specifies whether or not <i>Connex</i>t will store and deliver data that were previously published to new <i>DataReaders</i>. See <a href="#">47.9 DURABILITY QoS Policy on page 809</a>.</p>
EntityName	<p>Assigns a name to a <i>DataReader</i>. See <a href="#">47.11 ENTITY_NAME QoS Policy (DDS Extension) on page 817</a>.</p>
History	<p>Specifies how much data must be stored by <i>Connex</i>t for the <i>DataWriter</i> or <i>DataReader</i>. This QoS Policy affects the <a href="#">47.21 RELIABILITY QoS Policy on page 845</a> as well as the <a href="#">47.9 DURABILITY QoS Policy on page 809</a>. See <a href="#">47.12 HISTORY QoS Policy on page 818</a>.</p>
LatencyBudget	<p>Suggestion to <i>Connex</i>t on how much time is allowed to deliver data. See <a href="#">47.13 LATENCYBUDGET QoS Policy on page 823</a>.</p>
Liveliness	<p>Specifies and configures the mechanism that allows <i>DataReaders</i> to detect when <i>DataWriters</i> become disconnected or "dead." See <a href="#">47.15 LIVELINESS QoS Policy on page 825</a>.</p>
Property	<p>Stores name/value (string) pairs that can be used to configure certain parameters of <i>Connex</i>t that are not exposed through formal QoS policies. It can also be used to store and propagate application-specific name/value pairs, which can be retrieved by user code during discovery. See <a href="#">47.19 PROPERTY QoS Policy (DDS Extension) on page 837</a>.</p>
ReaderDataLifecycle	<p>Controls how a <i>DataReader</i> manages the lifecycle of the data that it has received. See <a href="#">48.3 READER_DATA_LIFECYCLE QoS Policy on page 885</a>.</p>
Reliability	<p>Specifies whether or not <i>Connex</i>t will deliver data reliably. See <a href="#">47.21 RELIABILITY QoS Policy on page 845</a>.</p>
ResourceLimits	<p>Controls the amount of physical memory allocated for entities, if dynamic allocations are allowed, and how they occur. Also controls memory usage among different instance values for keyed topics. See <a href="#">47.22 RESOURCE_LIMITS QoS Policy on page 850</a>.</p>
Service	<p>Intended for use by RTI infrastructure services. User applications should not modify its value. See <a href="#">47.23 SERVICE QoS Policy (DDS Extension) on page 853</a>.</p>

**Table 40.13 DataReader QoS Policies**

QoS Policy	Description
TimeBasedFilter	Set by a <i>DataReader</i> to limit the number of new data values received over a period of time. See <a href="#">48.4 TIME_BASED_FILTER QoS Policy on page 888</a> .
TransportMulticast	Specifies the multicast address on which a <i>DataReader</i> wants to receive its data. Can specify a port number as well as a subset of the available transports with which to receive the multicast data. See <a href="#">48.5 TRANSPORT_MULTICAST QoS Policy (DDS Extension) on page 891</a> .
TransportPriority	Set by a <i>DataReader</i> to tell <i>Connex</i> t that the data being sent is a different "priority" than other data. See <a href="#">47.26 TRANSPORT_PRIORITY QoS Policy on page 856</a> .
TransportSelection	Allows you to select which physical transports a <i>DataWriter</i> or <i>DataReader</i> may use to send or receive its data. See <a href="#">47.27 TRANSPORT_SELECTION QoS Policy (DDS Extension) on page 858</a> .
TransportUnicast	Specifies a subset of transports and port number that can be used by an Entity to receive data. See <a href="#">47.28 TRANSPORT_UNICAST QoS Policy (DDS Extension) on page 859</a> .
TypeConsistencyEnforcement	Defines rules that determine whether the type used to publish a given data stream is consistent with that used to subscribe to it. See <a href="#">48.6 TYPE_CONSISTENCY_ENFORCEMENT QoS Policy on page 894</a> .
TypeSupport	Used to attach application-specific value(s) to a <i>DataWriter</i> or <i>DataReader</i> . These values are passed to the serialization or deserialization routine of the associated data type. Also controls whether padding bytes are set to 0 during serialization. See <a href="#">47.29 TYPESUPPORT QoS Policy (DDS Extension) on page 863</a> .
UserData	Along with Topic Data QoS Policy and Group Data QoS Policy, used to attach a buffer of bytes to <i>Connex</i> t's discovery meta-data. See <a href="#">47.30 USER_DATA QoS Policy on page 864</a> .

For a *DataReader* to communicate with a *DataWriter*, their corresponding QoS Policies must be compatible. For QoS Policies that apply both to the *DataWriter* and the *DataReader*, the setting in the *DataWriter* is considered what the *DataWriter* “offers” and the setting in the *DataReader* is what the *DataReader* “requests.” Compatibility means that what is offered by the *DataWriter* equals or surpasses what is requested by the *DataReader*. See [42.1 QoS Requested vs. Offered Compatibility—the RxO Property on page 687](#).

Some of the policies may be changed after the *DataReader* has been created. This allows the application to modify the behavior of the *DataReader* while it is in use. To modify the QoS of an already-created *DataReader*, use the `get_qos()` and `set_qos()` operations on the *DataReader*. This is a general pattern for all *Entities*, described in [49.3 Changing the QoS for an Existing Entity on page 903](#).

### 40.9.1 Configuring QoS Settings when the DataReader is Created

As described in [40.1 Creating DataReaders on page 620](#), there are different ways to create a *DataReader*, depending on how you want to specify its QoS (with or without a QoS Profile).

- In [Figure 40.1: Creating a DataReader with Default QoS Policies on page 621](#), there is an example of how to create a *DataReader* with default QoS Policies by using the special constant, `DDS_DATAREADER_QOS_DEFAULT`, which indicates that the default QoS values for a *DataReader* should be used. The default *DataReader* QoS values are configured in the

*Subscriber* or *DomainParticipant*; you can change them with `set_default_datareader_qos()` or `set_default_datareader_qos_with_profile()`. Then any *DataReaders* created with the *Subscriber* will use the new default values. As described in [Chapter 49 Configuring QoS Programmatically on page 900](#), this is a general pattern that applies to the construction of all *Entities*.

- To create a *DataReader* with non-default QoS without using a QoS Profile, see the example code in [Figure 40.6: Creating a DataReader with Modified QoS Policies \(not from a profile\) below](#). It uses the *Subscriber's* `get_default_reader_qos()` method to initialize a `DDS_DataReaderQos` structure. Then the policies are modified from their default values before the structure is used in the `create_datareader()` method.
- You can also create a *DataReader* and specify its QoS settings via a QoS Profile. To do so, you will call `create_datareader_with_profile()`, as seen in [Figure 40.7: Creating a DataReader with a QoS Profile on the next page](#).
- If you want to use a QoS profile, but then make some changes to the QoS before creating the *DataReader*, call `get_datawriter_qos_from_profile()` and `create_datawriter()` as seen in [Figure 40.8: Getting QoS Values from Profile, Changing QoS Values, Creating DataReader with Modified QoS Values on the next page](#).

For more information, see [31.1 Creating DataWriters on page 393](#) and [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

#### Notes:

- The examples in this section use the Traditional C++ API; for examples in the Modern C++ API, see the sections "DataReader Use Cases," "QoS Use Cases," and "QoS Provider Use Cases" in the API Reference HTML documentation, under "Programming How-To's."
- In C, you must initialize the QoS structures before they are used, see [42.2 Special QoS Policy Handling Considerations for C on page 688](#).

**Figure 40.6: Creating a DataReader with Modified QoS Policies (not from a profile)**

```
DDS_DataReaderQos reader_qos;
// initialize reader_qos with default values
subscriber->get_default_datareader_qos(reader_qos);
// make QoS changes
reader_qos.history.depth = 5;
// Create the reader with modified qos
DDSDataReader * reader = subscriber->create_datareader(
    topic, reader_qos, NULL, DDS_STATUS_MASK_NONE);
if (reader == NULL) {
    // ... error
}
// narrow it for your specific data type
FooDataReader* foo_reader = FooDataReader::narrow(reader);
```

Figure 40.7: Creating a DataReader with a QoS Profile

```
// Create the datareader
DDSDataReader * reader =
    subscriber->create_datareader_with_profile(
        topic, "MyReaderLibrary", "MyReaderProfile",
        NULL, DDS_STATUS_MASK_NONE);
if (reader == NULL) {
    // ... error
};
// narrow it for your specific data type
FooDataReader* foo_reader = FooDataReader::narrow(reader);
```

Figure 40.8: Getting QoS Values from Profile, Changing QoS Values, Creating DataReader with Modified QoS Values

```
DDS_DataReaderQos reader_qos;
// Get reader QoS from profile
retcode = factory->get_datareader_qos_from_profile(
    reader_qos, "ReaderProfileLibrary", "ReaderProfile");
if (retcode != DDS_RETCODE_OK) {
    // handle error
}
// Makes QoS changes
reader_qos.history.depth = 5;
DDSDataReader * reader = subscriber->create_datareader(
    topic, reader_qos, NULL, DDS_STATUS_MASK_NONE);
if (participant == NULL) {
    // handle error
}
```

## 40.9.2 Comparing QoS Values

The `equals()` operation compares two *DataReader*'s `DDS_DataReaderQoS` structures for equality. It takes two parameters for the two *DataReader*'s QoS structures to be compared, then returns `TRUE` if they are equal (all values are the same) or `FALSE` if they are not equal.

## 40.9.3 Changing QoS Settings After the DataReader has been Created

There are two ways to change an existing *DataReader*'s QoS after it has been created—again depending on whether or not you are using a QoS Profile.

- To change QoS programmatically (that is, without using a QoS Profile), use `get_qos()` and `set_qos()`. See the example code in [Figure 40.9: Changing the QoS of Existing DataReader \(without a QoS Profile\) on the next page](#). It retrieves the current values by calling the *DataWriter*'s `get_qos()` operation. Then it modifies the value and calls `set_qos()` to apply the new value. Note, however, that some QoS Policies cannot be changed after the *DataWriter* has been enabled—this

restriction is noted in the descriptions of the individual QoS Policies.

- You can also change a *DataReader's* (and all other *Entities'*) QoS by using a QoS Profile and calling `set_qos_with_profile()`. For an example, see [Figure 40.10: Changing the QoS of Existing DataReader with a QoS Profile below](#). For more information, see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

**Note:**

- In C, you must initialize the QoS structures before they are used, see [42.2 Special QoS Policy Handling Considerations for C on page 688](#).

**Figure 40.9: Changing the QoS of Existing DataReader (without a QoS Profile)**

```
DDS_DataReaderQos reader_qos;
// Get current QoS.
if (datareader->get_qos(reader_qos) != DDS_RETCODE_OK) {
    // handle error
}
// Makes QoS changes here
reader_qos.history.depth = 5;
// Set the new QoS
if (datareader->set_qos(reader_qos) != DDS_RETCODE_OK ) {
    // handle error
}
```

**Figure 40.10: Changing the QoS of Existing DataReader with a QoS Profile**

```
retcode = reader->set_qos_with_profile(
    "ReaderProfileLibrary", "ReaderProfile");
if (retcode != DDS_RETCODE_OK) {
    // handle error
}
```

## 40.9.4 Using a Topic's QoS to Initialize a DataReader's QoS

Several *DataReader* QoS Policies can also be found in the QoS Policies for *Topics* (see [18.1.3 Setting Topic QoS Policies on page 250](#)). The QoS Policies set in the Topic do not directly affect the *DataReaders* (or *DataWriters*) that use that *Topic*. In many ways, some QoS Policies are a *Topic*-level concept, even though the DDS standard allows you to set different values for those policies for different *DataWriters* and *DataReaders* of the same *Topic*. Thus, the policies in the **DDS\_TopicQoS** structure exist as a way to help centralize and annotate the intended or suggested values of those QoS Policies. *Connex* does not check to see if the actual policies set for a *DataReader* is aligned with those set in the *Topic* to which it is bound.

There are many ways to use the QoS Policies' values set in the *Topic* when setting the QoS Policies' values in a *DataReader*. The most straightforward way is to get the values of policies directly from the

*Topic* and use them in the policies for the *DataReader*, as shown in [Figure 40.11: Copying Selected QoS from a Topic when Creating a DataReader below](#).

**Note:**

- In C, you must initialize the QoS structures before they are used, see [42.2 Special QoS Policy Handling Considerations for C on page 688](#).

**Figure 40.11: Copying Selected QoS from a Topic when Creating a DataReader**

```
DDS_DataReaderQos reader_qos;
DDS_TopicQos topic_qos;
// topic and publisher already created
// get current QoS for the topic, default QoS for the reader
if (topic->get_qos(topic_qos) != DDS_RETCODE_OK) {
    // handle error
}
if (publisher->get_default_datareader_qos(reader_qos)
    != DDS_RETCODE_OK) {
    // handle error
}
// Copy specific policies from topic QoS to reader QoS
reader_qos.deadline = topic_qos.deadline;
reader_qos.reliability = topic_qos.reliability;
// Create the DataReader with the modified QoS
DDSDataReader* reader = publisher->create_datareader(topic,
    reader_qos, NULL, DDS_STATUS_MASK_NONE);
```

You can use the *Subscriber's* `copy_from_topic_qos()` operation to copy all of the common policies from the *Topic* QoS to a *DataReader* QoS. This is illustrated in [Figure 40.12: Copying all QoS from a Topic when Creating a DataReader below](#).

**Figure 40.12: Copying all QoS from a Topic when Creating a DataReader**

```
DDS_DataReaderQos reader_qos;
DDS_TopicQos topic_qos;
// topic, publisher, reader_listener already created
if (topic->get_qos(topic_qos) != DDS_RETCODE_OK) {
    // handle error
}
if (publisher->get_default_datareader_qos(reader_qos)
    != DDS_RETCODE_OK)
{
    // handle error
}
// copy relevant QoS from topic into reader's qos
publisher->copy_from_topic_qos(reader_qos, topic_qos);
// Optionally, modify policies as desired
reader_qos.deadline.duration.sec = 1;
reader_qos.deadline.duration.nanosec = 0;
// Create the DataReader with the modified QoS
```

```
DDSDataReader* reader = publisher->create_datareader(topic,
    reader_qos, reader_listener, DDS_STATUS_MASK_ALL);
```

The special macro, `DDS_DATAREADER_QOS_USE_TOPIC_QOS`, can be used to indicate that the *DataReader* should be created with the QoS that results from modifying the default *DataReader* QoS with the values specified by the *Topic*. See [Figure 31.15: Combining Default Topic and DataWriter QoS \(Option 1\) on page 441](#) and [Figure 31.16: Combining Default Topic and DataWriter QoS \(Option 2\) on page 442](#) for examples involving *DataWriters*. The same pattern applies to *DataReaders*.

For more information on the general use and manipulation of *QoS*Policies, see [Chapter 49 Configuring QoS Programmatically on page 900](#).

## 40.10 Navigating Relationships Among Entities

### 40.10.1 Finding Matching Publications

The following *DataReader* operations can be used to get information about the *DataWriters* that will send data to this *DataReader*. A publication consists of information about the *DataWriter* and its associated *Publisher* and *Topic*.

- `get_matched_publications()`
- `get_matched_publication_data()`

The `get_matched_publications()` operation will return a sequence of handles to matched *DataWriters*. You can use these handles in the `get_matched_publication_data()` method to get information about the *DataWriter* such as the values of its *QoS*Policies, as well as information about its *Publisher* and *Topic*.

Note that *DataWriters* that have been ignored using the *DomainParticipant*'s `ignore_publication()` operation are not considered to be matched even if the *DataWriter* has the same *Topic* and compatible *QoS*Policies. Thus, they will not be included in the list of *DataWriters* returned by `get_matched_publications()`. See [27.2 Ignoring Publications and Subscriptions on page 354](#) for more on `ignore_publication()`.

You can also get the `DATA_READER_PROTOCOL_STATUS` for matching publications with `get_matched_publication_datareader_protocol_status()` (see [40.7.3 DATA\\_READER\\_PROTOCOL\\_STATUS on page 630](#)).

#### Notes:

- The `get_matched_publications()` function includes the return of handles of matched *DataWriters* that are no longer alive. All of the handles returned by this function are valid inputs to the `get_matched_publication_data()` function.

- Status/data for a matched publication is kept even if the matched *DataWriter* is not alive. Status/data for a matched publication will be removed only if the *DataWriter* is gone: that is, the *DataWriter* is destroyed and this change is propagated through a discovery update, or the *DataWriter's DomainParticipant* is gone (either gracefully or its liveliness expired and *Connex* is configured to purge not-alive participants). Once a matched *DataWriter* is gone, its status is deleted. If you try to get the status/data for a matched *DataWriter* that is gone, the 'get status' or 'get data' call will return an error.
- If you want to know which matched *DataWriters* are not alive, use **is\_matched\_publication\_alive()**. See [Table 40.1 DataReader Operations on page 616](#).
- The **get\_matched\_publication\_data()** operation does not retrieve the **type\_code** information from built-in-topic data structures. This information is available through the **on\_data\_available()** callback (if a *DataReaderListener* is installed on the *PublicationBuiltinTopicDataDataReader*).

See also: [40.10.2 Finding the Matching Publication's ParticipantBuiltinTopicData below](#)

## 40.10.2 Finding the Matching Publication's ParticipantBuiltinTopicData

**get\_matched\_publication\_participant\_data()** allows you to get the *DDS\_ParticipantBuiltinTopicData* (see [Table 28.1 Participant Built-in Topic's Data Type \(DDS\\_ParticipantBuiltinTopicData\)](#)) of a matched publication using a publication handle.

This operation retrieves the information on a discovered *DomainParticipant* associated with the publication that is currently matching with the *DataReader*.

The publication handle passed into this operation must correspond to a publication currently associated with the *DataReader*. Otherwise, the operation will fail with `RETCODE_BAD_PARAMETER`. The operation may also fail with `RETCODE_PRECONDITION_NOT_MET` if the publication handle corresponds to the same *DomainParticipant* to which the *DataReader* belongs.

Use **get\_matched\_publications()** (see [40.10.1 Finding Matching Publications on the previous page](#)) to find the publications that are currently matched with the *DataReader*.

## 40.10.3 Finding a DataReader's Related Entities

These *DataReader* operations are useful for obtaining a handle to various related entities:

- **get\_subscriber()**
- **get\_topicdescription()**

The **get\_subscriber()** operation returns the *Subscriber* that created the *DataReader*. **get\_topicdescription()** returns the *Topic* with which the *DataReader* is associated.

## 40.10.4 Looking Up an Instance Handle

Some operations, such as `read_instance()` and `take_instance()`, take an `instance_handle` parameter. If you need to get such as handle, you can call the `lookup_instance()` operation, which takes an instance as a parameter and returns a handle to that instance.

## 40.10.5 Getting the Key Value for an Instance

If you have a handle to a data-instance, you can use the `FooDataReader`'s `get_key_value()` operation to retrieve the key for that instance. The value of the key is decomposed into its constituent fields and returned in a `Foo` structure. For information on keys and keyed data types, please see [Chapter 8 DDS Samples, Instances, and Keys on page 17](#).

# Chapter 41 Using DataReaders to Access Data (Read & Take)

For user applications to access the data received for a *DataReader*, they must use the type-specific derived class or set of functions in the C API. Thus for a user data type ‘**Foo**’, you must use methods of the **FooDataReader** class. The type-specific class or functions are automatically generated if you use *RTI Code Generator*. Else, you will have to create them yourself, see [17.2.8 Type Codes for Built-in Types on page 152](#) for more details.

## 41.1 Using a Type-Specific DataReader (FooDataReader)

This section doesn't apply to the Modern C++ API, where a *DataReader*'s data type is part of its template definition: **DataReader<Foo>**.

Using a *Subscriber* you will create a *DataReader* associating it with a specific data type, for example ‘**Foo**’. Note that the *Subscriber*'s **create\_datareader()** method returns a generic *DataReader*. When your code is ready to access *DDS* data samples received for the *DataReader*, you must use type-specific operations associated with the **FooDataReader**, such as **read()** and **take()**.

To cast the generic *DataReader* returned by **create\_datareader()** into an object of type **FooDataReader**, you should use the type-safe **narrow()** method of the **FooDataReader** class. **narrow()** will make sure that the generic *DataReader* passed to it is indeed an object of the **FooDataReader** class before it makes the cast. Else, it will return NULL. [Figure 39.8: Simple SubscriberListener on page 612](#) shows an example:

```
Foo_reader = FooDataReader::narrow(reader);
```

[Table 40.1 DataReader Operations](#) lists type-specific operations using a **FooDataReader**. Also listed are generic, non-type specific operations that can be performed using the base class object **DDSDataReader** (or **DDS\_DataReader** in C). In C, you must pass a pointer to a **DDS\_DataReader** to those generic functions.

## 41.2 Loaning and Returning Data and SampleInfo Sequences

### 41.2.1 C, Traditional C++, Java and .NET

The **read()** and **take()** operations (and their variations) return information to your application in two sequences:

- Received *DDS* data samples in a sequence of the data type
- Corresponding information about each DDS sample in a **SampleInfo** sequence

These sequences are parameters that are passed by your code into the **read()** and **take()** operations. If you use empty sequences (sequences that are initialized but have a maximum length of 0), *Connex* will fill those sequences with memory directly loaned from the receive queue itself. There is no copying of the data or of **SampleInfo** when the contents of the sequences are loaned. This is certainly the most efficient way for your code to retrieve the data.

However when you do so, your code must return the loaned sequences back to *Connex* so that they can be reused by the receive queue. If your code does not return the loan by calling the **FooDataReader**'s **return\_loan()** method, then *Connex* will eventually run out of memory to store *DDS* data samples received from the network for that *DataReader*. See [Figure 41.1: Using Loaned Sequences in read\(\) and take\(\) below](#) for an example of borrowing and returning loaned sequences.

```
DDS_ReturnCode_t return_loan(
    FooSeq &received_data, DDS_SampleInfoSeq &info_seq);
```

**Figure 41.1: Using Loaned Sequences in read() and take()**

```
// In C++ and Java, sequences are automatically initialized
// to be empty
FooSeq data_seq;
DDS_SampleInfoSeq info_seq;
DDS_ReturnCode_t retcode;
...
// with empty sequences, a take() or read() will return loaned
// sequence elements
retcode = Foo_reader->take(data_seq, info_seq,
    DDS_LENGTH_UNLIMITED, DDS_ANY_SAMPLE_STATE,
    DDS_ANY_VIEW_STATE, DDS_ANY_INSTANCE_STATE);
... // process the returned data
// must return the loaned sequences when done processing
Foo_reader->return_loan(data_seq, info_seq);
...
```

For the C API, you must use the **FooSeq\_initialize()** and **DDS\_SampleInfoSeq\_initialize()** operations or the macro **DDS\_SEQUENCE\_INITIALIZER** to initialize the **FooSeq** and **DDS\_SampleInfoSeq** to be empty. For example, `DDS_SampleInfoSeq infoSeq; DDS_SampleInfoSeq_initialize(&infoSeq);` or `FooSeq fooSeq = DDS_SEQUENCE_INITIALIZER;`

If your code provides its own sequences to the read/take operations, then *Connex*t will copy the data from the receive queue. In that case, you do not have to call `return_loan()` when you are finished with the data. However, you must make sure the following is true, or the read/take operation will fail with a return code of `DDS_RETCODE_PRECONDITION_NOT_MET`:

- The `received_data` of type `FooSeq` and `info_seq` of type `DDS_SampleInfoSeq` passed in as parameters have the same maximum size (length).
- The maximum size (length) of the sequences are less than or equal to the passed in parameter, `max_samples`.

## 41.2.2 Modern C++

The `read()` and `take()` operations (and their variations) return `LoanedSamples`, an iterable collection of loaned, read-only samples each containing the actual data and meta-information about the sample. A `LoanedSamples` collection automatically returns the loan to the middleware in its destructor. You can also explicitly call `LoanedSamples::return_loan()`.

Figure 41.2: Using `LoanedSamples` to read data

```
dds::sub::LoanedSamples<Foo> samples = reader.take();
for (auto sample : samples) { // process the data
    if (sample.info().valid()) {
        std::cout << sample.data() << std::endl;
    }
}
```

## 41.3 Accessing DDS Data Samples with Read or Take

To access the *DDS* data samples that *Connex*t has received for a *DataReader*, you must invoke the `read()` or `take()` methods. These methods return a list (sequence) of *DDS* data samples and additional information about the *DDS* samples in a corresponding list (sequence) of `SampleInfo` structures. The contents of `SampleInfo` are described in [41.6 The SampleInfo Structure on page 676](#).

Calling `read()`, `take()`, or one of their variations resets the `DATA_AVAILABLE` status.

The way *Connex*t builds the collection of *DDS* samples depends on QoS policies set on the *DataReader* and *Subscriber*, the `source_timestamp` of the *DDS* samples, and the `sample_states`, `view_states`, and `instance_states` parameters passed to the read/take operation.

In `read()` and `take()`, you may enter parameters so that *Connex*t selectively returns *DDS* data samples currently stored in the *DataReader*'s receive queue. You may want *Connex*t to return all of the data in a single list or only a subset of the available *DDS* samples as configured using the `sample_states`, `view_Connex`tstates, and `instance_states` masks. [41.6 The SampleInfo Structure on page 676](#) describes how these masks are used to determine which *DDS* data samples should be returned.

### 41.3.1 Read vs. Take

The difference between **read()** and **take()** is how *Connex* treats the data that is returned. With **take()**, *Connex* will remove the data from the *DataReader*'s receive queue. The data returned by *Connex* is no longer stored by *Connex*. With **read()**, *Connex* will continue to store the data in the *DataReader*'s receive queue. The same data may be read again until it is taken in subsequent **take()** calls. Note that the data stored in the *DataReader*'s receive queue may be overwritten, even if it has not been read, depending on the setting of the [47.12 HISTORY QosPolicy on page 818](#).

The **read()** and **take()** operations are non-blocking calls, so that they may return no data (**DDS\_RETCODE\_NO\_DATA**) if the receive queue is empty or has no data that matches the criteria specified by the **StateMasks**.

The **read\_w\_condition()** and **take\_w\_condition()** operations take a **ReadCondition** as a parameter instead of DDS sample, view or instance states. The only DDS samples returned will be those for which the **ReadCondition** is TRUE. These operations, in conjunction with **ReadConditions** and a **WaitSet**, allow you to perform 'waiting reads.' For more information, see [15.9.7 ReadConditions and QueryConditions on page 66](#).

As you will see, **read** and **take** have the same parameters:

```
DDS_ReturnCode_t read( FooSeq &received_data_seq,
    DDS_SampleInfoSeq &info_seq,
    DDS_Long max_samples,
    DDS_SampleStateMask sample_states,
    DDS_ViewStateMask view_states,
    DDS_InstanceStateMask instance_states);

DDS_ReturnCode_t take( FooSeq &received_data_seq,
    DDS_SampleInfoSeq &info_seq,
    DDS_Long max_samples,
    DDS_SampleStateMask sample_states,
    DDS_ViewStateMask view_states,
    DDS_InstanceStateMask instance_states);
```

**Note:** These operations may loan internal *Connex* memory, which must be returned with **return\_loan()**. See [41.2 Loaning and Returning Data and SampleInfo Sequences on page 664](#).

Both operations return an ordered collection of DDS data samples (in the **received\_data\_seq** parameter) and information about each DDS sample (in the **info\_seq** parameter). Exactly how they are ordered depends on the setting of the [46.6 PRESENTATION QosPolicy on page 760](#) and the [47.8 DESTINATION\\_ORDER QosPolicy on page 806](#). For more details please see the API Reference HTML documentation for **read()** and **take()**.

In **read()** and **take()**, you can use the **sample\_states**, **view\_states**, and **instance\_states** parameters to specify properties that are used to select the actual DDS samples that are returned by those methods. With different combinations of these three parameters, you can direct *Connex* to return all DDS data

samples, DDS data samples that you have not accessed before, the DDS data samples of instances that you have not seen before, DDS data samples of instances that have been disposed, etc. The possible values for the different states are described both in the API Reference HTML documentation and in [41.6 The SampleInfo Structure on page 676](#).

[Table 41.1 Read and Take Operations](#) lists the variations of the **read()** and **take()** operations.

Table 41.1 Read and Take Operations

Read Operations	Take Operations	Modern C++ <sup>1</sup>	Description	Reference
read	take	reader.read() or reader.select().state(...).read()	Reads/takes a collection of DDS data samples from the <i>DataReader</i> . Can be used for both keyed and non-keyed data types.	<a href="#">41.3 Accessing DDS Data Samples with Read or Take on page 665</a>
read_instance	take_instance	reader.select().instance(...).read()	Identical to <b>read()</b> and <b>take()</b> , but all returned DDS samples belong to a single instance, which you specify as a parameter. Can only be used with keyed data types.	<a href="#">41.3.4 read_instance and take_instance on page 670</a>
read_instance_w_condition	take_instance_w_condition	reader.select().instance().condition(...).read()	Identical to <b>read_instance()</b> and <b>take_instance()</b> , but all returned DDS samples belong to the single specified instance <i>and</i> satisfy the specified ReadCondition.	<a href="#">41.3.7 read_instance_w_condition and take_instance_w_condition on page 672</a>
read_next_instance	take_next_instance	reader.select().next_instance(...).read()	Similar to <b>read_instance()</b> and <b>take_instance()</b> , but the actual instance is not directly specified as a parameter. Instead, the DDS samples will all belong to instance ordered after the instance that is specified by the previous_handle parameter.	<a href="#">41.3.5 read_next_instance and take_next_instance on page 670</a>
read_next_instance_w_condition	take_next_instance_w_condition	reader.select().next_instance(...).condition(...).read()	Accesses a collection of DDS data samples of the next instance that match a specific set of ReadConditions, from the <i>DataReader</i> .	<a href="#">41.3.8 read_next_instance_w_condition and take_next_instance_w_condition on page 673</a>
read_next_sample	take_next_sample	reader.select().state(DataState::not_read()).read()	Provides a convenient way to access the next DDS DDS sample in the receive queue that has not been accessed before.	<a href="#">41.3.3 read_next_sample and take_next_sample on the next page</a>
read_w_condition	take_w_condition	reader.select().condition(...)	Accesses a <i>collection</i> of DDS data samples from the <i>DataReader</i> that match specific ReadCondition criteria.	<a href="#">41.3.6 read_w_condition and take_w_condition on page 672</a>

## 41.3.2 General Patterns for Accessing Data

Once the DDS data samples are available to the data readers, the DDS samples can be read or taken by the application. The basic rule is that the application may do this in any order it wishes. This approach is very flexible and allows the application ultimate control.

To access data coherently, or in order, the [46.6 PRESENTATION QosPolicy on page 760](#) must be set properly.

### Accessing DDS samples If No Order or Coherence Is Required

<sup>1</sup>For the Modern C++, only the read() operation is shown; the take() variant is parallel.

Simply access the data by calling read/take on each *DataReader* in any order you want.

You do not have to call **begin\_access()** and **end\_access()**. However, doing so is not an error and it will have no effect.

You can call the *Subscriber's* **get\_datareaders()** operation to see which *DataReaders* have data to be read, but you do not need to read all of them or read them in a particular order. The **get\_datareaders()** operation will return a logical 'set' in the sense that the same *DataReader* will not appear twice. The order of the *DataReaders* returned is not specified.

### Accessing DDS samples within a SubscriberListener

This case describes how to access the data inside the listener's **on\_data\_on\_readers()** operation (regardless of the PRESENTATION QoS policy settings).

To do so, you can call read/take on each *DataReader* in any order. You can also delegate accessing of the data to the *DataReaderListeners* by calling the *Subscriber's* **notify\_datareaders()** operation.

Similar to the previous case, you can still call the *Subscriber's* **get\_datareaders()** operation to determine which *DataReaders* have data to be read, but you do not have to read all of them, or read them in a particular order. **get\_datareaders()** will return a logical 'set.'

You do not have to call **begin\_access()** and **end\_access()**. However, doing so is not an error and it will have no effect.

### 41.3.3 read\_next\_sample and take\_next\_sample

The **read\_next\_sample()** or **take\_next\_sample()** operation is used to retrieve the next DDS sample that hasn't already been accessed. It is a simple way to 'read' DDS samples and frees your application from managing sequences and specifying DDS sample, instance or view states. It behaves the same as calling **read()** or **take()** with **max\_samples = 1**, **sample\_states = NOT\_READ**, **view\_states = ANY\_VIEW\_STATE**, and **instance\_states = ANY\_INSTANCE\_STATE**.

```
DDS_ReturnCode_t read_next_sample(
    Foo & received_data, DDS_SampleInfo & sample_info);
DDS_ReturnCode_t take_next_sample(
    Foo & received_data, DDS_SampleInfo & sample_info);
```

It copies the next, not-previously-accessed data value from the *DataReader*. It also copies the DDS sample's corresponding **DDS\_SampleInfo** structure.

If there is no unread data in the *DataReader*, the operation will return **DDS\_RETCODE\_NO\_DATA** and nothing is copied.

Since this operation copies both the DDS data sample and the **SampleInfo** into user-provided storage, it does not allocate nor loan memory. You do not have to call **return\_loan()** after this operation.

**Note:** If the `received_data` parameter references a structure that contains a sequence and that sequence has not been initialized, the operation will return `DDS_RETCODE_ERROR`.

### 41.3.4 read\_instance and take\_instance

The `read_instance()` and `take_instance()` operations are identical to `read()` and `take()`, but they are used to access DDS samples for just a specific instance (key value). The parameters are the same, except you must also supply an instance handle. These functions can only be used when the *DataReader* is tied to a keyed type, see [Chapter 8 DDS Samples, Instances, and Keys on page 17](#) for more about keyed data types.

These operations may return `BAD_PARAMETER` if the instance handle does not correspond to an existing data-object known to the *DataReader*.

The handle to a particular data instance could have been cached from a previous `read()` operation (value taken from the `SampleInfo` struct) or created by using the *DataReader*'s `lookup_instance()` operation.

```
DDS_ReturnCode_t read_instance(
    FooSeq &received_data,
    DDS_SampleInfoSeq &info_seq,
    DDS_Long max_samples,
    const DDS_InstanceHandle_t &a_handle,
    DDS_SampleStateMask sample_states,
    DDS_ViewStateMask view_states,
    DDS_InstanceStateMask instance_states);
```

**Note:** This operation may loan internal *Connex* memory, which must be returned with `return_loan()`. See [41.2 Loaning and Returning Data and SampleInfo Sequences on page 664](#).

### 41.3.5 read\_next\_instance and take\_next\_instance

The `read_next_instance()` and `take_next_instance()` operations are similar to `read_instance()` and `take_instance()` in that they return DDS samples for a specific data instance (key value). The difference is that instead of passing the handle of the data instance for which you want DDS data samples, instead you pass the handle to a 'previous' instance. The returned DDS samples will all belong to the 'next' instance, where the ordering of instances is explained below.

```
DDS_ReturnCode_t read_next_instance(
    FooSeq &received_data,
    DDS_Long max_samples,
    const DDS_InstanceHandle_t &previous_handle
    DDS_SampleStateMask sample_states,
    DDS_ViewStateMask view_states,
    DDS_InstanceStateMask instance_states)
```

Connex orders all instances relative to each other. This ordering depends on the value of the key as defined for the data type associated with the *Topic*. For the purposes of this discussion, it is 'as if' each instance handle is represented by a unique integer and thus different instance handles can be ordered by their value. (The ordering of the instances is specific to each implementation of the DDS standard; to maximize the portability of your code, do not assume any particular order. In the case of Connex, and likely other DDS implementations, the order is not likely to be meaningful to you as a developer; it is simply important that some ordering exists.)

This operation will return values for the *next* instance handle that has DDS data samples stored in the receive queue (that meet the criteria specified by the **StateMasks**). The *next* instance handle will be ordered after the **previous\_handle** that is passed in as a parameter.

The special value **DDS\_HANDLE\_NIL** can be passed in as the **previous\_handle**. Doing so, you will receive values for the “smallest” instance handle that has DDS data samples stored in the receive queue that you have not yet accessed.

You can call the **read\_next\_instance()** operation with a **previous\_handle** that does not correspond to an instance currently managed by the *DataReader*. For example, you could use this approach to iterate through all the instances, take all the DDS samples with a **NOT\_ALIVE\_NO\_WRITERS** instance\_state, return the loans (at which point the instance information may be removed, and thus the handle becomes invalid), and then try to read the next instance.

The example below shows how to use **take\_next\_instance()** iteratively to process all the data received for an instance, one instance at a time. We always pass in **DDS\_HANDLE\_NIL** as the value of **previous\_handle**. Each time through the loop, we will receive DDS samples for a different instance, since the previous time through the loop, all of the DDS samples of the previous instance were returned (and thus accessed).

In the C API, you must use the **FooSeq\_initialize()** and **DDS\_SampleInfoSeq\_initialize()** operations or the macro **DDS\_SEQUENCE\_INITIALIZER** to initialize the *FooSeq* and *DDS\_SampleInfoSeq* to be empty. For example, `DDS_SampleInfoSeq infoSeq; DDS_SampleInfoSeq_initialize(&infoSeq);` or `FooSeq fooSeq = DDS_SEQUENCE_INITIALIZER;`

```

FooSeq received_data;
DDS_SampleInfoSeq info_seq;
while (retcode = reader->take_next_instance(received_data, info_seq,
    DDS_LENGTH_UNLIMITED, DDS_HANDLE_NIL,
    DDS_ANY_SAMPLE_STATE, DDS_ANY_VIEW_STATE,
    DDS_ANY_INSTANCE_STATE)
    != DDS_RETCODE_NO_DATA) {
    // the data samples returned in received_data will all
    // be for a single instance
    // process the data
    // now return the loaned sequences
    if (reader->return_loan(received_data, info_seq)
        != DDS_RETCODE_OK) {
        // handle error
    }
}

```

**Note:** This operation may loan internal *Connex* memory, which must be returned with **return\_loan()**. See [41.2 Loaning and Returning Data and SampleInfo Sequences on page 664](#).

### 41.3.6 read\_w\_condition and take\_w\_condition

The **read\_w\_condition()** and **take\_w\_condition()** operations are identical to **read()** and **take()**, but instead of passing in the `sample_states`, `view_states`, and `instance_states` mask parameters directly, you pass in a `ReadCondition` (which specifies these masks).

```

DDS_ReturnCode_t read_w_condition (
    FooSeq &received_data,
    DDS_SampleInfoSeq &info_seq,
    DDS_Long max_samples,
    DDSReadCondition *condition)

```

**Note:** This operation may loan internal *Connex* memory, which must be returned with **return\_loan()**. See [41.2 Loaning and Returning Data and SampleInfo Sequences on page 664](#).

### 41.3.7 read\_instance\_w\_condition and take\_instance\_w\_condition

The **read\_instance\_w\_condition()** and **take\_instance\_w\_condition()** operations are similar to **read\_instance()** and **take\_instance()**, respectively, except that the returned DDS samples must also satisfy a specified `ReadCondition`.

```

DDS_ReturnCode_t read_instance_w_condition(
    FooSeq & received_data,
    DDS_SampleInfoSeq & info_seq,
    DDS_Long max_samples,
    const DDS_InstanceHandle_t & a_handle,
    DDSReadCondition * condition);

```

The behavior of **read\_instance\_w\_condition()** and **take\_instance\_w\_condition()** follows the same rules as **read()** and **take()** regarding pre-conditions and post-conditions for the **received\_data** and **sample\_info** parameters.

These functions can only be used when the *DataReader* is tied to a keyed type, see [Chapter 8 DDS Samples, Instances, and Keys](#) on page 17 for more about keyed data types.

Similar to **read()**, these operations must be provided on the specialized class that is generated for the particular application data-type that is being accessed.

**Note:** These operations may loan internal *Connex* memory, which must be returned with **return\_loan()**. See [41.2 Loaning and Returning Data and SampleInfo Sequences](#) on page 664.

### 41.3.8 read\_next\_instance\_w\_condition and take\_next\_instance\_w\_condition

The **read\_next\_instance\_w\_condition()** and **take\_next\_instance\_w\_condition()** operations are identical to **read\_next\_instance()** and **take\_next\_instance()**, but instead of passing in the `sample_states`, `view_states`, and `instance_states` mask parameters directly, you pass in a `ReadCondition` (which specifies these masks).

```
DDS_ReturnCode_t read_next_instance_w_condition (
    FooSeq &received_data,
    DDS_SampleInfoSeq &info_seq,
    DDS_Long max_samples,
    const DDS_InstanceHandle_t &previous_handle,
    DDSReadCondition *condition)
```

**Note:** This operation may loan internal *Connex* memory, which must be returned with **return\_loan()**. See [41.2 Loaning and Returning Data and SampleInfo Sequences](#) on page 664.

### 41.3.9 The select() API (Modern C++ and C#)

The Modern C++ API combines all the previous ways to read data into a single operation: **reader.select()**. This call is followed by one or more calls to functions that configure the query and always ends in a call to **read()** or **take()**. These are the functions that configure a **select()**:

Function	Description	Default
<code>max_samples()</code>	Specifies the maximum number of samples to read or take in this call	Up to the value specified in <a href="#">max_samples_per_read on page 877</a>
<code>instance()</code>	Specifies an instance to read or take	All instances
<code>next_instance()</code>	Indicates that read or take should return samples for the instance that follows the one being passed (Note: both <code>next_instance()</code> and <code>instance()</code> can't be specified at the same time)	All instances
<code>state()</code>	Specifies the sample state, view state and instance state	All samples
<code>content()</code>	Specifies a query on the data values to read	All samples
<code>condition()</code>	Specifies a condition (see <code>read_w_condition()</code> ). If <code>condition()</code> is specified <code>state()</code> and <code>content()</code> cannot be specified.  When running a query more than once on the same <code>DataReader</code> , it is more efficient to create a <code>QueryCondition</code> and pass it to <code>condition()</code> rather than using <code>content()</code> .	All samples

To read or take using the default options, simply call `reader.read()` or `reader.take()` with no arguments.

The following examples show how to call `select()`:

#### In Modern C++:

```
dds::sub::LoanedSamples<Foo> samples =
    reader.select()
        .max_samples(20)
        .state(dds::sub::status::DataState::new_instance())
        .content(dds::sub::Query(reader, "x > 10"))
        .instance(my_instance_handle)
        .take();
```

#### In C#:

```
var queryCondition = reader.CreateQueryCondition("x > 10");
using LoanedSamples<Foo> samples = reader.Select()
    .WithMaxSamples(20)
    .WithCondition(queryCondition)
    .WithInstance(myInstanceHandle)
    .Take();
```

**Note:** `Content()` is only supported in the Modern C++ API.

## 41.4 Acknowledging DDS Samples

DDS samples can be acknowledged one at a time, or as a group.

To explicitly acknowledge a single DDS sample:

```
DDS_ReturnCode_t acknowledge_sample (
    const DDS_SampleInfo & sample_info);
DDS_ReturnCode_t acknowledge_sample (
    const DDS_SampleInfo & sample_info,
    const DDS_AckResponseData_t & response_data);
```

Or you may acknowledge all previously accessed DDS samples by calling:

```
DDS_ReturnCode_t DDSDataReader::acknowledge_all ()
DDS_ReturnCode_t DDSDataReader::acknowledge_all (
    const DDS_AckResponseData_t & response_data)
```

Where:

**sample\_info** is of type `DDS_SampleInfo`, identifying the DDS sample being acknowledged

**response\_data** is response data sent to the `DataWriter` upon acknowledgment

These operations can only be used when the *DataReader's* [47.21 RELIABILITY QoSPolicy on page 845](#) has an **acknowledgment\_kind** set to `DDS_APPLICATION_EXPLICIT_ACKNOWLEDGMENT_MODE`. You must also set **max\_app\_ack\_response\_length** (in the [48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QoSPolicy \(DDS Extension\) on page 876](#)) to a value greater than zero.

See also: [31.12 Application Acknowledgment on page 418](#) and [Guaranteed Delivery of Data \(Chapter 33 on page 485\)](#).

## 41.5 The Sequence Data Structure

(This section doesn't apply to the Modern C++ API)

The DDS specification uses sequences whenever a variable-length array of elements must be passed through the API. This includes passing QoS Policies into *Connex*, as well as retrieving DDS data samples from *Connex*. A sequence is an ordered collection of elements of the same type. The type of a sequence containing elements of type “**Foo**” (whether “**Foo**” is one of your types or a built-in *Connex* type) is typically called “**FooSeq**.”

In all APIs except Java, **FooSeq** contains deep copies of **Foo** elements; in Java, which does not provide direct support for deep copy semantics, **FooSeq** contains references to **Foo** objects. In Java, sequences implement the `java.util.List` interface, and thus support all of the collection APIs and idioms familiar to Java programmers.

A sequence is logically composed of three things: an array of elements, a *maximum* number of elements that the array may contain (i.e. its allocated size), and a logical *length* indicating how many of the allocated elements are valid. The length may vary dynamically between 0 and the maximum (inclusive); it is not permissible to access an element at an index greater than or equal to the length.

A sequence may either “own” the memory associated with it, or it may “borrow” that memory. If a sequence owns its own memory, then the sequence itself will allocate the its memory and is permitted to grow and shrink that memory (i.e. change its maximum) dynamically.

You can also loan a sequence of memory using the sequence-specific operations `loan_contiguous()` or `loan_discontiguous()`. This is useful if you want *Connex* to copy the received DDS data samples directly into data structures allocated in user space.

Please do not confuse (a) the user loaning memory to a sequence with (b) *Connex* loaning internal memory from the receive queue to the user code via the **read()** or **take()** operations. For sequences of user data, these are complementary operations. **read()** and **take()** loan memory to the user, passing in a sequence that has been loaned memory with **loan\_contiguous()** or **loan\_discontiguous()**.

A sequence with loaned of memory may not change its maximum size.

#### For C developers:

In C, because there is no concept of a constructor, sequences must be initialized before they are used. You can either set a sequence equal to the macro **DDS\_SEQUENCE\_INITIALIZER** or use a sequence-specific method, **<type>Seq\_initialize()**, to initialize sequences.

#### For Traditional C++ and C# developers:

Traditional C++ sequence classes overload the **[ ]** operators to allow you to access their elements as if the sequence were a simple array. However, for code portability reasons, *Connex*'s Traditional C++ implementation of sequences does not use the Standard Template Library (STL).

#### For Java developers:

In Java, sequences implement the **List** interface, and typically, a **List** must contain **Objects**; it cannot contain primitive types directly. This restriction makes **Lists** of primitives types less efficient because each type must be wrapped and unwrapped into and from an **Object** as it is added to and removed from the **List**.

*Connex* provides a more efficient implementation for sequences of primitive types. In *Connex*, primitive sequence types (e.g., **IntSeq**, **FloatSeq**, etc.) are implemented as wrappers around arrays of primitive types. The wrapper also provides the usual **List** APIs; however, these APIs manipulate **Objects** that store the primitive type.

More efficient APIs are also provided that manipulate the primitive types directly and thus avoid unnecessary memory allocations and type casts. These additional methods are named according to the pattern **<standard method><primitive type>**; for example, the **IntSeq** class defines methods **addInt()** and **getInt()** that correspond to the **List** APIs **add()** and **get()**. **addInt()** and **getInt()** directly manipulate **int** values while **add()** and **get()** manipulate **Objects** that contain a single **int**.

For more information on sequence APIs in all languages, please consult the API Reference HTML documentation (from the main page, select **Modules**, **RTI Connex API Reference**, **Infrastructure Module**, **Sequence Support**).

## 41.6 The SampleInfo Structure

When you invoke the **read/take** operations, for every DDS data sample that is returned, a corresponding **SampleInfo** is also returned. **SampleInfo** structures provide you with additional information about the DDS data samples received by *Connex*.

[Table 41.2 DDS\\_SampleInfo Structure](#) shows the format of the **SampleInfo** structure.

Table 41.2 DDS\_SampleInfo Structure

Type	Field Name	Description
DDS_SampleStateKind	sample_state	See <a href="#">41.6.2 Sample States on page 679</a>
DDS_ViewStateKind	view_state	See <a href="#">41.6.3 View States on page 680</a>
DDS_InstanceStateKind	instance_state	See <a href="#">40.8.1 Instance States on page 644</a>
DDS_Time_t	source_timestamp	Time stored by the <i>DataWriter</i> when the DDS sample was written.
DDS_InstanceHandle_t	instance_handle	Handle to the data-instance corresponding to the DDS sample.
DDS_InstanceHandle_t	publication_handle	Local handle to the <i>DataWriter</i> that modified the instance. This is the same instance handle returned by <b>get_matched_publications()</b> . You can use this handle when calling <b>get_matched_publication_data()</b> .
DDS_Long	disposed_generation_count	See <a href="#">40.8.2 Generation Counts and Ranks on page 646</a> .
	no_writers_generation_count	
	sample_rank	
	generation_rank	
	absolute_generation_rank	
DDS_Boolean	valid_data	Indicates whether the DDS data sample includes valid data. See <a href="#">40.8.3 Valid Data Flag on page 648</a> .
DDS_Time_t	reception_timestamp	Time stored when the DDS sample was committed by the <i>DataReader</i> . See <a href="#">41.6.1 Reception Timestamp on page 679</a> .
DDS_SequenceNumber_t	publication_sequence_number	Publication sequence number assigned when the DDS sample was written by the <i>DataWriter</i> .
DDS_SequenceNumber_t	reception_sequence_number	Reception sequence number assigned when the DDS sample was committed by the <i>DataReader</i> . See <a href="#">41.6.1 Reception Timestamp on page 679</a> .
struct DDS_GUID_t	original_publication_virtual_guid	Original publication virtual GUID. If the <i>Publisher's</i> <b>access_scope</b> is GROUP, this field contains the <i>Publisher</i> virtual GUID that uniquely identifies the <i>DataWriter</i> group.
struct DDS_SequenceNumber_t	original_publication_virtual_sequence_number	Original publication virtual sequence number. If the <i>Publisher's</i> <b>access_scope</b> is GROUP, this field contains the <i>Publisher</i> virtual sequence number that uniquely identifies a DDS sample within the <i>DataWriter</i> group.

Table 41.2 DDS\_SampleInfo Structure

Type	Field Name	Description
DDS_GUID_t	topic_query_guid	<p>The GUID of the DDS_TopicQuery that is related to the sample.</p> <p>This GUID indicates whether a sample is part of the response to a DDS_TopicQuery or a regular ("live") sample: If the sample was written for the TopicQuery stream, this field contains the GUID of the target TopicQuery. If the sample was written for the live stream, this field will be set to DDS_GUID_UNKNOWN.</p>
DDS_Long	flag	<p>Flags associated with the DDS sample; set by using the <b>flag</b> field in DDS_WriteParams_t when writing a DDS sample with <b>FooDataWriter_write_w_params()</b> (see <a href="#">31.8 Writing Data on page 410</a>).</p> <p>RTI reserves least-significant bits [0-7] for middleware-specific usage. The application can use least significant bits [8-15].</p> <p>The first bit, REDELIVERED_SAMPLE, is reserved to mark a DDS sample as redelivered when using RTI Queuing Service.</p> <p>The second bit, INTERMEDIATE_REPLY_SEQUENCE_SAMPLE, is used to indicate that a response DDS sample is not the last response DDS sample for a given request. This bit is usually set by Connex Repliers sending multiple responses for a request.</p> <p>The third bit, REPLICATE_SAMPLE, indicates if a sample must be broadcast by one Queuing Service replica to other replicas.</p> <p>The fourth bit, LAST_SHARED_READER_QUEUE_SAMPLE, indicates that a sample is the last sample in a SharedReaderQueue for a QueueConsumer DataReader.</p> <p>The fifth bit, INTERMEDIATE_TOPIC_QUERY_SAMPLE, indicates that a sample for a TopicQuery will be followed by more samples. This flag only applies to samples that have been published as a response to a TopicQuery. When this bit is not set and <a href="#">topic_query_guid</a> is different from GUID_UNKNOWN, this sample is the last sample for that TopicQuery coming from the <i>DataWriter</i> identified by <a href="#">original_publication_virtual_guid on the previous page</a>.</p> <p>The sixth bit, WRITER_REMOVED_BATCH_SAMPLE, will be set if the sample was accepted into the <i>DataReader</i> queue even though it was marked by the <i>DataWriter</i> as removed. Examples of removed samples in a batch are samples that were replaced due to <a href="#">KEEP_LAST_HISTORY_QOS on the DataWriter (see 47.12 HISTORY QoS Policy on page 818)</a> or samples that outlived the <i>DataWriter's</i> <a href="#">47.14 LIFESPAN QoS Policy on page 824</a> duration. If the <i>DataReader</i> sets the property <code>dds.data_reader.accept_writer_removed_batch_samples</code> to true (in the <a href="#">47.19 PROPERTY QoS Policy (DDS Extension) on page 837</a>), the removed sample will be accepted into the <i>DataReader</i> queue and this flag will be set.</p>
struct DDS_GUID_t	source_guid	The application logical data source associated with the sample.
struct DDS_GUID_t	related_source_guid	The application logical data source that is related to the sample.

Table 41.2 DDS\_SampleInfo Structure

Type	Field Name	Description
struct DDS_GUID_t	related_subscription_guid	The related_reader_guid associated with the sample.
struct DDS_CoherentSetInfo_t	coherent_set_info	<p>Information about the coherent set that this sample is a part of. This field is set for all samples that are part of a coherent set. This field contains the following members:</p> <ul style="list-style-type: none"> <li>group_guid identifies the <i>DataWriter</i> or the group of <i>DataWriters</i> publishing the coherent set, depending on the value of the <i>Subscriber's access_scope</i> in the <a href="#">46.6 PRESENTATION QosPolicy on page 760</a>. (If <b>access_scope</b> is TOPIC or INSTANCE, then group_guid identifies a single <i>DataWriter</i>; if <b>access_scope</b> is GROUP, then group_guid identifies all the <i>DataWriters</i> within a <i>Publisher</i>.)</li> <li>coherent_set_sequence_number identifies a sample as part of a <i>DataWriter</i> coherent set. When the <i>Subscriber's access_scope</i> in the <a href="#">46.6 PRESENTATION QosPolicy on page 760</a> is TOPIC or INSTANCE, the coherent set associated with a sample is identified by the pair (group_guid, coherent_set_sequence_number).</li> <li>group_coherent_set_sequence_number identifies a sample as part of a group coherent set. When the <i>Subscriber's access_scope</i> in the <a href="#">46.6 PRESENTATION QosPolicy on page 760</a> is GROUP, the coherent set associated with a sample is identified by the pair (group_guid, group_coherent_set_sequence_number).</li> <li>incomplete_coherent_set indicates if a sample is part of an incomplete coherent set. An incomplete coherent set is a coherent set for which not all samples have been received. Note that a coherent set is also considered incomplete if some of its samples are filtered by content or time on the <i>DataWriter</i> side. By default, received samples from an incomplete coherent set are not provided to the application and they are reported as LOST_BY_INCOMPLETE_COHERENT_SET (see <a href="#">40.7.7 SAMPLE_LOST Status on page 636</a>). You can change this behavior by setting <b>drop_incomplete_coherent_set</b> to FALSE in the <a href="#">46.6 PRESENTATION QosPolicy on page 760</a>.</li> </ul>

## 41.6.1 Reception Timestamp

In reliable communication, if DDS data samples are received out of order, *Connex* will not deliver them until all the previous DDS data samples have been received. For example, if DDS sample 2 arrives before DDS sample 1, DDS sample 2 cannot be delivered until DDS sample 1 is received. The **reception\_timestamp** is the time when all previous DDS samples has been received—the time at which the DDS sample is *committed*. If DDS samples are all received in order, the committed time will be same as reception time. However, if DDS samples are lost on the wire, then the committed time will be later than the initial reception time.

## 41.6.2 Sample States

For each DDS sample received, *Connex* keeps a **sample\_state** relative to each *DataReader*. The **sample\_state** can be either:

- **READ**: The *DataReader* has already accessed that DDS sample by means of **read()**.
- **NOT\_READ**: The *DataReader* has never accessed that DDS sample before.

The DDS samples retrieved by a **read()** or **take()** need not all have the same **sample\_state**.

### 41.6.3 View States

For each instance (identified by a unique key value), *Connex*t keeps a **view\_state** relative to each *DataReader*. The **view\_state** can be either:

- **NEW**: Either this is the first time the *DataReader* has ever accessed DDS samples of the instance, or the *DataReader* has accessed previous DDS samples of the instance, but the instance has since been reborn (i.e., become not-alive and then alive again). These two cases are distinguished by examining the **disposed\_generation\_count** and the **no\_writers\_generation\_count** (see [40.8.2 Generation Counts and Ranks on page 646](#)).
- **NOT\_NEW**: The *DataReader* has already accessed DDS samples of the same instance and the instance has not been reborn since.

The **view\_state** in the **SampleInfo** structure is really a per-instance concept (as opposed to the **sample\_state** which is per DDS sample). Thus all DDS data samples related to the same instance that are returned by **read()** or **take()** will have the same value for **view\_state**.

### 41.6.4 Instance States

*Connex*t keeps an **instance\_state** for each instance; it can be:

- **ALIVE**
- **NOT\_ALIVE\_DISPOSED**
- **NOT\_ALIVE\_NO\_WRITERS**

For more information, see [40.8.1 Instance States on page 644](#).

### 41.6.5 Generation Counts and Ranks

Each *DataReader* keeps two counters for each *new* instance it detects (recall that instances are distinguished by their key values):

- **disposed\_generation\_count**
- **no\_writers\_generation\_count**

For more information, see [40.8.2 Generation Counts and Ranks on page 646](#).

### 41.6.6 Valid Data Flag

The **SampleInfo** structure's **valid\_data** flag indicates whether the DDS sample contains data or is only used to communicate a change in the **instance\_state** of the instance.

For more information, see [40.8.3 Valid Data Flag on page 648](#).

# Part 7: Configuring ConnexT Using QoS

This section includes:

- [All QoS Policies \(Chapter 42 on page 683\)](#)
- [DomainParticipantFactory QoS Policies \(Chapter 43 on page 690\)](#)
- [DomainParticipant QoS Policies \(Chapter 44 on page 696\)](#)
- [Topic QoS Policies \(Chapter 45 on page 737\)](#)
- [Publisher/Subscriber QoS Policies \(Chapter 46 on page 740\)](#)
- [DataWriter QoS Policies \(Chapter 47 on page 768\)](#)
- [DataReader QoS Policies \(Chapter 48 on page 870\)](#)
- [Configuring QoS Programmatically \(Chapter 49 on page 900\)](#)
- [Configuring QoS with XML \(Chapter 50 on page 905\)](#)

## Chapter 42 All QosPolicies

*Connex*'s behavior is controlled by the Quality of Service (QoS) policies of the data communication *Entities* (*DomainParticipant*, *Topic*, *Publisher*, *Subscriber*, *DataWriter*, and *DataReader*) used in your applications. This section summarizes each of the QosPolicies that you can set for the various *Entities*.

The *QosPolicy* class is the abstract base class for all the QosPolicies. It provides the basic mechanism for an application to specify quality of service parameters. [Table 42.1 QosPolicies](#) lists each supported QosPolicy (in alphabetical order), provides a summary, and points to a section in the manual that provides further details.

The detailed description of a QosPolicy that applies to multiple *Entities* is provided in the first chapter that discusses an *Entity* whose behavior the QoS affects. Otherwise, the discussion of a QosPolicy can be found in the chapter of the particular *Entity* to which the policy applies. As you will see in the detailed description sections, all QosPolicies have one or more parameters that are used to configure the policy. The how's and why's of tuning the parameters are also discussed in those sections.

As first discussed in [Chapter 11 Quality of Service \(QoS\) on page 26](#), QosPolicies may interact with each other, and certain values of QosPolicies can be incompatible with the values set for other policies.

The `set_qos()` operation will fail if you attempt to specify a set of values that would result in an inconsistent set of policies. To indicate a failure, `set_qos()` will return `INCONSISTENT_POLICY`. [42.1 QoS Requested vs. Offered Compatibility—the RxO Property on page 687](#) provides further information on QoS compatibility within an *Entity* as well as across matching *Entities*, as does the discussion/reference section for each QosPolicy listed in [Table 42.1 QosPolicies](#).

The values of some QosPolicies cannot be changed after the *Entity* is created or after the *Entity* is enabled. Others may be changed at any time. The detailed section on each QosPolicy states when each policy can be changed. If you attempt to change a QosPolicy after it becomes immut-

able (because the associated *Entity* has been created or enabled, depending on the policy), `set_qos()` will fail with a return code of `IMMUTABLE_POLICY`.

Table 42.1 QosPolicies

QosPolicy	Summary
Asynchronous-Publisher	Configures the mechanism that sends user data in an external middleware thread. See <a href="#">46.1 ASYNCHRONOUS_PUBLISHER QosPolicy (DDS Extension) on page 740</a> .
Availability	This QoS policy is used in the context of two features: For a <i>Collaborative DataWriter</i> , specifies the group of <i>DataWriters</i> expected to collaboratively provide data and the timeouts that control when to allow data to be available that may skip DDS samples. For a <i>Durable Subscription</i> , configures a set of Durable Subscriptions on a <i>DataWriter</i> . See <a href="#">47.1 AVAILABILITY QosPolicy (DDS Extension) on page 769</a> .
Batch	Specifies and configures the mechanism that allows <i>Connex</i> t to collect multiple DDS data samples to be sent in a single network packet, to take advantage of the efficiency of sending larger packets and thus increase effective throughput. See <a href="#">47.2 BATCH QosPolicy (DDS Extension) on page 773</a> .
Database	Various settings and resource limits used by <i>Connex</i> t to control its internal database. See <a href="#">44.1 DATABASE QosPolicy (DDS Extension) on page 696</a> .
DataReaderProtocol	This QosPolicy configures the <i>Connex</i> t on-the-network protocol, RTPS. See <a href="#">48.1 DATA_READER_PROTOCOL QosPolicy (DDS Extension) on page 871</a> .
DataReaderResourceLimits	Various settings that configure how <i>DataReaders</i> allocate and use physical memory for internal resources. See <a href="#">48.2 DATA_READER_RESOURCE_LIMITS QosPolicy (DDS Extension) on page 876</a> .
DataRepresentation	Specifies which versions of the Extended Common Data Representation (CDR) (version 1 or version 2) and which data compression setting algorithms are offered and requested for your data. See <a href="#">47.3 DATA_REPRESENTATION QosPolicy on page 780</a> .
DataTag	This QosPolicy can be used to associate a set of tags in the form of (name, value) pairs with a <i>DataReader</i> or <i>DataWriter</i> . The Access Control plugin may use these tags to determine publish and subscribe permissions. See <a href="#">47.4 DATATAG QosPolicy on page 787</a> .
DataWriterProtocol	This QosPolicy configures the <i>Connex</i> t on-the-network protocol, RTPS. See <a href="#">47.5 DATA_WRITER_PROTOCOL QosPolicy (DDS Extension) on page 788</a> .
DataWriterResourceLimits	Controls how many threads can concurrently block on a <code>write()</code> call of this <i>DataWriter</i> . Also controls the number of batches managed by the <i>DataWriter</i> and the instance-replacement kind used by the <i>DataWriter</i> . See <a href="#">47.6 DATA_WRITER_RESOURCE_LIMITS QosPolicy (DDS Extension) on page 800</a> .
Deadline	For a <i>DataReader</i> , specifies the maximum expected elapsed time between arriving DDS data samples. For a <i>DataWriter</i> , specifies a commitment to publish DDS samples with no greater elapsed time between them. See <a href="#">47.7 DEADLINE QosPolicy on page 804</a> .
DestinationOrder	Controls how <i>Connex</i> t will deal with data sent by multiple <i>DataWriters</i> for the same topic. Can be set to "by reception timestamp" or to "by source timestamp." See <a href="#">47.8 DESTINATION_ORDER QosPolicy on page 806</a> .
Discovery	Configures the mechanism used by <i>Connex</i> t to automatically discover and connect with new remote applications. See <a href="#">44.2 DISCOVERY QosPolicy (DDS Extension) on page 699</a> .
DiscoveryConfig	Controls the amount of delay in discovering <i>Entities</i> in the system and the amount of discovery traffic in the network. See <a href="#">44.3 DISCOVERY_CONFIG QosPolicy (DDS Extension) on page 703</a> .

Table 42.1 QoS Policies

QoS Policy	Summary
DomainParticipantResourceLimits	Various settings that configure how <i>DomainParticipants</i> allocate and use physical memory for internal resources, including the maximum sizes of various properties. See <a href="#">44.4 DOMAIN_PARTICIPANT_RESOURCE_LIMITS QoS Policy (DDS Extension) on page 714</a> .
Durability	Specifies whether or not <i>Connex</i> t will store and deliver data that were previously published to new <i>DataReaders</i> . See <a href="#">47.9 DURABILITY QoS Policy on page 809</a> .
DurabilityService	Various settings to configure the external Persistence Service used by <i>Connex</i> t for <i>DataWriters</i> with a Durability QoS setting of Persistent Durability. See <a href="#">47.10 DURABILITY SERVICE QoS Policy on page 814</a> .
EntityFactory	Controls whether or not child <i>Entities</i> are created in the enabled state. See <a href="#">46.2 ENTITYFACTORY QoS Policy on page 743</a> .
EntityName	Assigns a name and role_name to an <i>Entity</i> . See <a href="#">47.11 ENTITY_NAME QoS Policy (DDS Extension) on page 817</a> .
Event	Configures the <i>DomainParticipant's</i> internal thread that handles timed events. See <a href="#">44.5 EVENT QoS Policy (DDS Extension) on page 721</a> .
ExclusiveArea	Configures multi-thread concurrency and deadlock prevention capabilities. See <a href="#">46.3 EXCLUSIVE_AREA QoS Policy (DDS Extension) on page 746</a> .
GroupData	Along with <a href="#">45.1 TOPIC_DATA QoS Policy on page 737</a> and <a href="#">47.30 USER_DATA QoS Policy on page 864</a> , this QoS Policy is used to attach a buffer of bytes to <i>Connex</i> t's discovery meta-data. See <a href="#">46.4 GROUP_DATA QoS Policy on page 748</a> .
History	Specifies how much data must be stored by <i>Connex</i> t for the <i>DataWriter</i> or <i>DataReader</i> . This QoS Policy affects the <a href="#">47.21 RELIABILITY QoS Policy on page 845</a> as well as the <a href="#">47.9 DURABILITY QoS Policy on page 809</a> . See <a href="#">47.12 HISTORY QoS Policy on page 818</a> .
LatencyBudget	Suggestion to <i>Connex</i> t on how much time is allowed to deliver data. See <a href="#">47.13 LATENCYBUDGET QoS Policy on page 823</a> .
Lifespan	Specifies how long <i>Connex</i> t should consider data sent by an user application to be valid. See <a href="#">47.14 LIFESPAN QoS Policy on page 824</a> .
Liveliness	Specifies and configures the mechanism that allows <i>DataReaders</i> to detect when <i>DataWriters</i> become disconnected or "dead." See <a href="#">47.15 LIVELINESS QoS Policy on page 825</a> .
Logging	Configures the properties associated with <i>Connex</i> t logging. See <a href="#">43.1 LOGGING QoS Policy (DDS Extension) on page 690</a> .
MultiChannel	Configures a <i>DataWriter's</i> ability to send data on different multicast groups (addresses) based on the value of the data. See <a href="#">47.16 MULTI_CHANNEL QoS Policy (DDS Extension) on page 830</a> .
Ownership	Along with Ownership Strength, specifies if <i>DataReaders</i> for a topic can receive data from multiple <i>DataWriters</i> at the same time. See <a href="#">47.17 OWNERSHIP QoS Policy on page 833</a> .
OwnershipStrength	Used to arbitrate among multiple <i>DataWriters</i> of the same instance of a Topic when Ownership QoS Policy is EXCLUSIVE. See <a href="#">47.18 OWNERSHIP_STRENGTH QoS Policy on page 836</a> .
Partition	Adds string identifiers that are used for matching <i>DataReaders</i> and <i>DataWriters</i> for the same <i>Topic</i> or for matching <i>DomainParticipants</i> with the same domain ID and domain tag. See <a href="#">46.5 PARTITION QoS Policy on page 751</a> .
Presentation	Controls how <i>Connex</i> t presents data received by an application to the <i>DataReaders</i> of the data. See <a href="#">46.6 PRESENTATION QoS Policy on page 760</a> .
Profile	Configures the way that XML documents containing QoS profiles are loaded by RTI. See <a href="#">43.2 PROFILE QoS Policy (DDS Extension) on page 691</a> .

Table 42.1 QoS Policies

QoS Policy	Summary
Property	Stores name/value(string) pairs that can be used to configure certain parameters of <i>Connex</i> t that are not exposed through formal QoS policies. It can also be used to store and propagate application-specific name/value pairs, which can be retrieved by user code during discovery. See <a href="#">47.19 PROPERTY QoS Policy (DDS Extension) on page 837</a> .
PublishMode	Specifies how <i>Connex</i> t sends application data on the network. By default, data is sent in the user thread that calls the <i>DataWriter</i> 's <code>write()</code> operation. However, this QoS Policy can be used to tell <i>Connex</i> t to use its own thread to send the data. See <a href="#">47.20 PUBLISH_MODE QoS Policy (DDS Extension) on page 843</a> .
ReaderDataLifeCycle	Controls how a <i>DataReader</i> manages the lifecycle of the data that it has received. See <a href="#">48.3 READER_DATA_LIFECYCLE QoS Policy on page 885</a> .
ReceiverPool	Configures threads used by <i>Connex</i> t to receive and process data from transports (for example, UDP sockets). See <a href="#">44.6 RECEIVER_POOL QoS Policy (DDS Extension) on page 723</a> .
Reliability	Specifies whether or not <i>Connex</i> t will deliver data reliably. See <a href="#">47.21 RELIABILITY QoS Policy on page 845</a> .
ResourceLimits	Controls the amount of physical memory allocated for <i>Entities</i> , if dynamic allocations are allowed, and how they occur. Also controls memory usage among different instance values for keyed topics. See <a href="#">47.22 RESOURCE_LIMITS QoS Policy on page 850</a> .
Service	Intended for use by RTI infrastructure services. User applications should not modify its value. See <a href="#">47.23 SERVICE QoS Policy (DDS Extension) on page 853</a> .
SystemResourceLimits	Configures <i>DomainParticipant</i> -independent resources used by <i>Connex</i> t. Mainly used to change the maximum number of <i>DomainParticipants</i> that can be created within a single process (address space). See <a href="#">43.3 SYSTEM_RESOURCE_LIMITS QoS Policy (DDS Extension) on page 693</a> .
TimeBasedFilter	Set by a <i>DataReader</i> to limit the number of new data values received over a period of time. See <a href="#">48.4 TIME_BASED_FILTER QoS Policy on page 888</a> .
TopicData	Along with Group Data QoS Policy and User Data QoS Policy, used to attach a buffer of bytes to <i>Connex</i> t's discovery metadata. See <a href="#">45.1 TOPIC_DATA QoS Policy on page 737</a> .
TopicQueryDispatch	Configures the ability of a <i>DataWriter</i> to publish historical samples in response to a TopicQuery. See <a href="#">47.24 TOPIC_QUERY_DISPATCH_QoS Policy (DDS Extension) on page 854</a> .
TransferMode	Configures the properties of a Zero Copy <i>DataWriter</i> . See <a href="#">47.25 TRANSFER_MODE QoS Policy on page 855</a> .
TransportBuiltin	Specifies which built-in transport plugins are used. See <a href="#">44.7 TRANSPORT_BUILTIN QoS Policy (DDS Extension) on page 725</a> .
TransportMulticast	Specifies the multicast address on which a <i>DataReader</i> wants to receive its data. Can specify a port number as well as a subset of the available transports with which to receive the multicast data. See <a href="#">48.5 TRANSPORT_MULTICAST QoS Policy (DDS Extension) on page 891</a> .
TransportMulticastMapping	Specifies the automatic mapping between a list of topic expressions and multicast address that can be used by a <i>DataReader</i> to receive data for a specific topic. See <a href="#">44.8 TRANSPORT_MULTICAST_MAPPING QoS Policy (DDS Extension) on page 727</a> .
TransportPriority	Set by a <i>DataWriter</i> or <i>DataReader</i> to tell <i>Connex</i> t that the data being sent is a different "priority" than other data. See <a href="#">47.26 TRANSPORT_PRIORITY QoS Policy on page 856</a> .
TransportSelection	Allows you to select which physical transports a <i>DataWriter</i> or <i>DataReader</i> may use to send or receive its data. See <a href="#">47.27 TRANSPORT_SELECTION QoS Policy (DDS Extension) on page 858</a> .
TransportUnicast	Specifies a subset of transports and port number that can be used by an Entity to receive data. See <a href="#">47.28 TRANSPORT_UNICAST QoS Policy (DDS Extension) on page 859</a> .

Table 42.1 QoS Policies

QoS Policy	Summary
TypeConsistencyEnforcement	Defines rules that determine whether the type used to publish a given data stream is consistent with that used to subscribe to it. See <a href="#">48.6 TYPE_CONSISTENCY_ENFORCEMENT QoS Policy on page 894</a> .
TypeSupport	Used to attach application-specific value(s) to a <i>DataWriter</i> or <i>DataReader</i> . These values are passed to the serialization or deserialization routine of the associated data type. Also controls whether padding bytes are set to 0 during serialization. See <a href="#">47.29 TYPESUPPORT QoS Policy (DDS Extension) on page 863</a> .
UserData	Along with Topic Data QoS Policy and Group Data QoS Policy, used to attach a buffer of bytes to <i>Connex</i> 's discovery metadata. See <a href="#">47.30 USER_DATA QoS Policy on page 864</a> .
WireProtocol	Specifies IDs used by the RTPS wire protocol to create globally unique identifiers. See <a href="#">44.9 WIRE_PROTOCOL QoS Policy (DDS Extension) on page 730</a> .
WriterDataLifeCycle	Controls how a <i>DataWriter</i> handles the lifecycle of the instances (keys) that the <i>DataWriter</i> is registered to manage. See <a href="#">47.31 WRITER_DATA_LIFECYCLE QoS Policy on page 866</a> .

## 42.1 QoS Requested vs. Offered Compatibility—the RxO Property

Some QoS Policies that apply to *Entities* on the sending and receiving sides must have their values set in a compatible manner. This is known as the policy's 'requested vs. offered' (RxO) property. *Entities* on the publishing side 'offer' to provide a certain behavior. *Entities* on the subscribing side 'request' certain behavior. For *Connex* to connect the sending entity to the receiving entity, the offered behavior must satisfy the requested behavior.

For some QoS Policies, the allowed values may be graduated in a way that the offered value will satisfy the requested value if the offered value is either greater than or less than the requested value. For example, if a *DataWriter*'s DEADLINE QoS Policy specifies a duration less than or equal to a *DataReader*'s DEADLINE QoS Policy, then the *DataWriter* is promising to publish data at least as fast or faster than the *DataReader* requires new data to be received. This is a compatible situation (see [47.7 DEADLINE QoS Policy on page 804](#)).

Other QoS Policies require the values on the sending side and the subscribing side to be exactly equal for compatibility to be met. For example, if a *DataWriter*'s OWNERSHIP QoS Policy is set to SHARED, and the matching *DataReader*'s value is set to EXCLUSIVE, then this is an incompatible situation since the *DataReader* and *DataWriter* have different expectations of what will happen if more than one *DataWriter* publishes an instance of the *Topic* (see [47.17 OWNERSHIP QoS Policy on page 833](#)).

Finally there are QoS Policies that do not require compatibility between the sending entity and the receiving entity, or that only apply to one side or the other. Whether or not related *Entities* on the publishing and subscribing sides must use compatible settings for a QoS Policy is indicated in the policy's RxO property, which is provided in the detailed section on each QoS Policy.

- **RxO = YES** The policy is set at both the publishing and subscribing ends and the values must be set in a compatible manner. What it means to be compatible is defined by the QosPolicy.
- **RxO = NO** The policy is set only on one end or at both the publishing and subscribing ends, but the two settings are independent. There the requested vs. offered semantics are not used for these QosPolicies.

For those QosPolicies that follow the RxO semantics, *Connex* will compare the values of those policies for compatibility. If they are compatible, then *Connex* will connect the sending entity to the receiving entity allowing data to be sent between them. If they are found to be incompatible, then *Connex* will not interconnect the *Entities* preventing data to be sent between them.

In addition, *Connex* will record this event by changing the associated communication status in both the sending and receiving applications, see [15.7.1 Types of Communication Status on page 40](#). Also, if you have installed *Listeners* on the associated *Entities*, then *Connex* will invoke the associated callback functions to notify user code that an incompatible QoS combination has been found, see [15.8.1 Types of Listeners on page 47](#).

For *Publishers* and *DataWriters*, the status corresponding to this situation is **OFFERED\_INCOMPATIBLE\_QOS\_STATUS**. For *Subscribers* and *DataReaders*, the corresponding status is **REQUESTED\_INCOMPATIBLE\_QOS\_STATUS**. The question of why a *DataReader* is not receiving data sent from a matching *DataWriter* can often be answered if you have instrumented the application with *Listeners* for the statuses noted previously.

## 42.2 Special QosPolicy Handling Considerations for C

Many QosPolicy structures contain variable-length sequences to store their parameters. In the C++, C# and Java languages, the memory allocation related to sequences are handled automatically through constructors/destructors and overloaded operators. However, the C language is limited in what it provides to automatically handle memory management. Thus, *Connex* provides functions and macros in C to initialize, copy, and finalize (free) QosPolicy structures defined for *Entities*.

In the C language, it is not safe to use an *Entity*'s QosPolicy structure declared in user code unless it has been initialized first. In addition, user code should always finalize an *Entity*'s QosPolicy structure to release any memory allocated for the sequences—even if the *Entity*'s QosPolicy structure was declared as a local, stack variable.

Thus, for a general *Entity*'s QosPolicy, *Connex* will provide:

- **DDS\_<Entity>Qos\_INITIALIZER** This is a macro that should be used when a **DDS\_<Entity>Qos** structure is declared in a C application.

```
struct DDS_<Entity>Qos qos = DDS_<Entity>Qos_INITIALIZER;
```

- **DDS\_<Entity>Qos\_initialize()** This is a function that can be used to initialize a **DDS\_<Entity>Qos** structure instead of the macro above.

```
struct DDS_<Entity>Qos qos;  
DDS_<Entity>QOS_initialize(&qos);
```

- **DDS\_<Entity>Qos\_finalize()** This is a function that should be used to finalize a **DDS\_<Entity>Qos** structure when the structure is no longer needed. It will free any memory allocated for sequences contained in the structure.

```
struct DDS_<Entity>Qos qos = DDS_<Entity>Qos_INITIALIZER;  
...  
<use qos>  
...  
// now done with qos  
DDS_<Entity>QoS_finalize(&qos);
```

- **DDS<Entity>Qos\_copy()** This is a function that can be used to copy one **DDS\_<Entity>Qos** structure to another. It will copy the sequences contained in the source structure and allocate memory for sequence elements if needed. In the code below, both **dstQos** and **srcQos** must have been initialized at some point earlier in the code.

```
DDS_<Entity>QOS_copy(&dstQos, &srcQos);
```

# Chapter 43 DomainParticipantFactory QoS Policies

This section describes QoS Policies that are strictly for the *DomainParticipantFactory* (not the *DomainParticipant*). For a complete list of QoS Policies that apply to *DomainParticipantFactory*, see [Table 16.2 DomainParticipantFactory QoS](#).

- [43.1 LOGGING QoS Policy \(DDS Extension\) below](#)
- [43.2 PROFILE QoS Policy \(DDS Extension\) on the next page](#)
- [43.3 SYSTEM\\_RESOURCE\\_LIMITS QoS Policy \(DDS Extension\) on page 693](#)

## 43.1 LOGGING QoS Policy (DDS Extension)

This QoS Policy configures the properties associated with the *Connex* logging facility.

This QoS Policy includes the members in [Table 43.1 DDS\\_LoggingQoS Policy](#). For defaults and valid ranges, please refer to the API Reference HTML documentation.

See also: [54.2 Configuring Connex Logging on page 1089](#) and [54.3 Configuring Logging via XML on page 1099](#).

**Table 43.1 DDS\_LoggingQoS Policy**

Type	Field Name	Description
NDDS_ConfigLogVerbosity	verbosity	Specifies the verbosity at which <i>Connex</i> diagnostic information will be logged.
NDDS_Config_LogCategory	category	Specifies the category for which logging needs to be enabled.
NDDS_Config_LogPrintFormat	print_format	Specifies the format to be used to output <i>Connex</i> diagnostic information.
char *	output_file	Specifies the file to which the logged output is redirected.
char *	output_file_suffix	Sets the file suffix when logging to a set of files.

Table 43.1 DDS\_LoggingQosPolicy

Type	Field Name	Description
DDS_Long	max_bytes_per_file	Specifies the maximum number of bytes a single file can contain.
DDS_Long	max_files	Specifies the maximum number of files to create before overwriting the previous ones.

### 43.1.1 Example

```

DDSDomainParticipantFactory *factory =
    DDSDomainParticipantFactory::get_instance();
DDS_DomainParticipantFactoryQos factoryQos;
DDS_ReturnCode_t retcode = factory->get_qos(factoryQos);
if (retcode != DDS_RETCODE_OK) {
    // error
}
factoryQos.logging.output_file = DDS_String_dup("myOutput.txt");
factoryQos.logging.verbosity = NDDS_CONFIG_LOG_VERBOSITY_STATUS_LOCAL;
factory->set_qos(factoryQos);

```

### 43.1.2 Properties

This QosPolicy can be changed at any time.

Since it is only configuring logging, there are no compatibility restrictions for how it is set on the publishing and subscribing sides.

### 43.1.3 Related QosPolicies

- None

### 43.1.4 Applicable DDS Entities

- [16.2 DomainParticipantFactory on page 75](#)

### 43.1.5 System Resource Considerations

Because the **output\_file** will be freed by *Connex*, you should use **DDS\_String\_dup()** to allocate the string when providing an **output\_file**.

## 43.2 PROFILE QosPolicy (DDS Extension)

This QosPolicy determines the way that XML documents containing QoS profiles are loaded.

All QoS values for *Entities* can be configured with QoS profiles defined in XML documents. XML documents can be passed to *Connex* in string form, or more likely, through files found on a file system. This QoS configures how a *DomainParticipantFactory* loads the QoS profiles defined in XML. QoS

profiles may be stored in this QoS as XML documents as a string. The location of XML files defining QoS profiles may be configured via this QoS. There are also default locations where the *DomainParticipantFactory* will look for files to load QoS profiles. You may disable any or all of these default locations using the Profile QoS. For more information about QoS profiles and libraries, please see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

This QoSPolicy includes the members in [Table 43.2 DDS\\_ProfileQoSPolicy](#). For the defaults and valid ranges, please refer to the API Reference HTML documentation.

**Table 43.2 DDS\_ProfileQoSPolicy**

Type	Field Name	Description
DDS_StringSeq	string_profile	Sequence of strings (empty by default) containing an XML document to load. The concatenation of the strings in this sequence must be a valid XML document according to the XML QoS profile schema.
	url_profile	A sequence of XML files (empty by default) containing a set of XML documents to load. See <a href="#">50.5 How to Load XML-Specified QoS Settings on page 939</a> .
DDS_Boolean	ignore_user_profile	When TRUE, the QoS profiles contained in the file <b>USER_QOS_PROFILES.xml</b> in the current working directory will be ignored.
	ignore_environment_profile	When TRUE, the value of the environment variable <b>NDDS_QOS_PROFILES</b> will be ignored.
	ignore_resource_profile	When TRUE, the QoS profiles in the file <b>\$NDDSHOME/resource/xml/NDDS_QOS_PROFILES.xml</b> will be ignored. <b>NDDS_QOS_PROFILES.xml</b> does not exist by default. However, <b>NDDS_QOS_PROFILES.example.xml</b> is shipped with the host bundle of the product; you can copy it to <b>NDDS_QOS_PROFILES.xml</b> and modify it for your own use.

In the Modern C++ API, there is not a PROFILE QoSPolicy, because the class that manages QoS profiles is `dds::core::QoSProvider`—not the `DomainParticipantFactory`. A `QoSProvider` can receive a `QoSProviderParams` instance, which encapsulates the fields described before.

## 43.2.1 Example

Traditional C++:

```
DDSDomainParticipantFactory *factory =
    DDSDomainParticipantFactory::get_instance();
DDS_DomainParticipantFactoryQos factoryQos;

DDS_ReturnCode_t retcode = factory->get_qos(factoryQos);
if (retcode != DDS_RETCODE_OK) {
    // error
}
const char *url_profiles[2] = {
    "file://usr/local/default_dds.xml",
    "file://usr/local/alternative_default_dds.xml" };
factoryQos.profile.url_profile.from_array(url_profiles, 2);
```

```
factoryQos.profile.ignore_resource_profile = DDS_BOOLEAN_TRUE;
factory->set_qos(factoryQos);
```

### Modern C++:

```
rti::core::QosProviderParams params =
    dds::core::QosProvider::Default()->default_provider_params();

std::vector<std::string> url_profiles = {
    "file://usr/local/default_dds.xml",
    "file://usr/local/alternative_default_dds.xml" };

params.url_profile(url_profiles);
params.ignore_resource_profile(true);

dds::core::QosProvider::Default()->default_provider_params(params);
```

## 43.2.2 Properties

This QoS policy can be changed at any time.

Since it is only for the DomainParticipantFactory, there are no compatibility restrictions for how it is set on the publishing and subscribing sides.

### 43.2.3 Related QoS Policies

- None

### 43.2.4 Applicable Entities

- [16.2 DomainParticipantFactory on page 75](#)

### 43.2.5 System Resource Considerations

Once the QoS profiles are loaded, the DomainParticipantFactory will keep one copy of each QoS in the QoS profiles in memory.

You can free the memory associated with the XML QoS profiles by calling the DomainParticipantFactory's **unload\_profiles()** operation.

## 43.3 SYSTEM\_RESOURCE\_LIMITS QoS Policy (DDS Extension)

The SYSTEM\_RESOURCE\_LIMITS QoS policy configures *DomainParticipant*-independent resources used by *Connex*. Its main use is to change the maximum number of *DomainParticipants* that can be created within a single process (address space).

It contains the members shown in [Table 43.3 DDS\\_SystemResourceLimitsQoSPolicy](#). For the valid ranges, please refer to the API Reference HTML documentation.

Table 43.3 DDS\_SystemResourceLimitsQoSPolicy

Type	Field Name	Description
DDS_Long	max_objects_per_thread	Sizes the thread storage that is allocated on a per-thread basis when the thread calls <i>Connex</i> t APIs. Leave this property set to the default value to allow the infrastructure to grow as needed. If you wish to strictly control memory allocation, you may set <b>max_objects_per_thread</b> to a smaller value, but note that this runs the risk of a runtime error and reduced application functionality if your limit is reached. See details below. Default: 261120
DDS_Long	initial_objects_per_thread	Sets the initial allocation of the thread storage that is allocated on a per-thread basis when the thread calls <i>Connex</i> t APIs. The infrastructure will grow automatically, up to a maximum of <b>max_objects_per_thread</b> , as required by the application at runtime. See details below. Default: 1024

**max\_objects\_per\_thread** controls the size of thread-specific storage that is allocated by *Connex*t for every thread that invokes a *Connex*t API. This storage is used to cache objects that have to be created on a per-thread basis when a thread traverses different portions of *Connex*t internal code.

Instead of dynamically creating and destroying the objects as a thread enters and leaves different parts of the code, *Connex*t caches the objects by storing them in thread-specific storage. We assume that a thread will repeatedly call *Connex*t APIs so that the objects cached will be needed again and again.

The number of objects that will be stored in the cache depends on the number of unique code paths that a thread invokes. It also depends on the number of different *DomainParticipants* with which the thread interacts.

The number of allowed objects per thread is automatically increased by *Connex*t as needed. (It starts at **initial\_objects\_per\_thread** and increases as needed, up to **max\_objects\_per\_thread**.) It is very unlikely that an application will benefit from explicitly setting **max\_objects\_per\_thread**. See [43.3.4 System Resource Considerations on the next page](#) for more discussion.

### 43.3.1 Properties

This QoS policy cannot be modified after the *DomainParticipantFactory* is used to create the first *DomainParticipant* or *WaitSet* in an application. Therefore, it cannot be set in an XML file—only in code.

This QoS can be set to different values in different applications without affecting interoperability.

### 43.3.2 Related QoS Policies

There are no interactions with other *QoSPolicies*.

### 43.3.3 Applicable DDS Entities

- [16.2 DomainParticipantFactory on page 75](#)

### 43.3.4 System Resource Considerations

**max\_objects\_per\_thread** is used to determine the size of an array of pointers to objects used in a thread. Increasing **max\_objects\_per\_thread** will increase the amount of memory allocated by *Connex* for every thread that accesses *Connex* code. This includes internal *Connex* threads as well as user threads.

While a small amount of memory may be conserved by setting **max\_objects\_per\_thread** carefully, this comes at the risk of generating a runtime exception if an application requires more thread-specific storage than allowed by the **max\_objects\_per\_thread** value chosen.

If you wish to ensure that the thread-specific storage infrastructure is allocated on application startup rather than on an as-needed basis, set the value of **initial\_objects\_per\_thread** equal to **max\_objects\_per\_thread**.

If you are certain that more than the default value of **initial\_objects\_per\_thread** will be required for your application and you wish to reduce the number of memory allocations performed while your application reaches steady state (i.e., reduce the number of automatic increases), you may set **initial\_objects\_per\_thread** to a larger number, although usually this is not necessary. To improve the efficiency of memory allocation, *Connex* may initially size the infrastructure to a larger value than the value of **initial\_objects\_per\_thread**. The infrastructure will never be sized less than **initial\_objects\_per\_thread** or greater than **max\_objects\_per\_thread**.

If you wish to observe when thread-specific storage is dynamically increased, increase the granularity of the debug level to LOCAL and observe the log messages indicating the initial value of **max\_objects\_per\_thread** and any automatic increases ("Allowed number of thread specific objects is now %d").

# Chapter 44 DomainParticipant QosPolicies

This section describes the QosPolicies that are strictly for *DomainParticipants* (and no other types of Entities). For a complete list of QosPolicies that apply to *DomainParticipant*, see [Table 16.5 DomainParticipant QosPolicies](#).

- [44.1 DATABASE QosPolicy \(DDS Extension\) below](#)
- [44.2 DISCOVERY QosPolicy \(DDS Extension\) on page 699](#)
- [44.3 DISCOVERY\\_CONFIG QosPolicy \(DDS Extension\) on page 703](#)
- [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 714](#)
- [44.5 EVENT QosPolicy \(DDS Extension\) on page 721](#)
- [44.6 RECEIVER\\_POOL QosPolicy \(DDS Extension\) on page 723](#)
- [44.7 TRANSPORT\\_BUILTIN QosPolicy \(DDS Extension\) on page 725](#)
- [44.8 TRANSPORT\\_MULTICAST\\_MAPPING QosPolicy \(DDS Extension\) on page 727](#)
- [44.9 WIRE\\_PROTOCOL QosPolicy \(DDS Extension\) on page 730](#)

## 44.1 DATABASE QosPolicy (DDS Extension)

The Database QosPolicy configures how *Connex* manages its internal database, including how often it cleans up, the priority of the database thread, and limits on resources that may be allocated by the database. RTI uses an internal in-memory database to store information about entities created locally as well as remote entities found during the discovery process. This database uses a background thread to garbage-collect records related to deleted entities. When the *DomainParticipant* that maintains this database is deleted, it shuts down this thread.

It includes the members in [Table 44.1 DDS\\_DatabaseQosPolicy](#). For defaults and valid ranges, please refer to the API Reference HTML documentation.

Table 44.1 DDS\_DatabaseQoSPolicy

Type	Field Name	Description
DDS_ThreadSettings_t	thread.mask thread.priority thread.stack_size	Thread settings for the database thread used by <i>Connex</i> t to periodically remove deleted records from the database. The values used for these settings are OS-dependent; see the <a href="#">RTI Connex</a> t Core Libraries Platform Notes for details. Note: thread.cpu_list and thread.cpu_rotation are not relevant in this QoS policy.
DDS_Duration_t	shutdown_timeout	The maximum time that the <i>DomainParticipant</i> will wait for the database thread to terminate when the participant is destroyed.
DDS_Duration_t	cleanup_period	The period at which the database thread wakes up to remove deleted records.
DDS_Duration_t	shutdown_cleanup_period	The cleanup period used during database shutdown. If you would like to shorten the time taken for a <i>DomainParticipant</i> to shut down, you can decrease this value. The default value is 10 milliseconds. It is recommended to set this value to something other than 0 if running in an RTOS environment, to avoid CPU starvation.
DDS_Long	initial_records	The number of records that is initially created for the database. These records hold information for both local and remote entities that are dynamically created or discovered.
DDS_Long	max_skiplist_level	This is a performance tuning parameter that optimizes the time it takes to search the database for a record. A 'Skip List' is an algorithm for maintaining a list that is faster to search than a binary tree. This value should be set to $\log_2(N)$ , where N is the maximum number of elements that will be stored in a single list. The list that stores the records for remote <i>DataReaders</i> or the one for remote <i>DataWriters</i> tend to have the most entries. So, the number of <i>DataWriters</i> or <i>DataReaders</i> in a system across all <i>DomainParticipants</i> in a single DDS domain, whichever is greater, can be used to set this parameter.
DDS_Long	max_weak_references	This parameter sets the maximum number of entries in the weak reference table. Weak references are used as a technique for ensuring that unreferenced objects are deleted. The actual number of weak references is permitted to grow from the value set by initial_weak_references to this maximum. To prevent <i>Connex</i> t from allocating memory for weak references after initialization, you should set the initial and maximum weak references to the same value. However, it is difficult to calculate how many weak references an application will use. To allow <i>Connex</i> t to grow the weak reference table as needed, and thus dynamically allocate memory, you should set the value of this field to DDS_LENGTH_UNLIMITED, the default setting.
DDS_Long	initial_weak_references	The initial number of entries in the weak reference table. See max_weak_references. <i>Connex</i> t may decide to use a larger initial value if initial_weak_references is set too small. If you access this parameter after a <i>DomainParticipant</i> has been created, you will see the actual value used.

You may be interested in modifying the **shutdown\_timeout** and **shutdown\_cleanup\_period** parameters to decrease the time it takes to delete a *DomainParticipant* when your application is shutting down.

The [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QoSPolicy \(DDS Extension\)](#) on page 714 controls the memory allocation for elements stored in the database.

Real-time programmers will probably want to adjust the priorities of all of the threads created by *Connex*t relative to each other as well as relative to non-*Connex*t threads in their applications. [Part 11](#):

---

[Connexth Threading Model \(on page 1180\)](#), [44.5 EVENT QosPolicy \(DDS Extension\) on page 721](#), and [44.6 RECEIVER\\_POOL QosPolicy \(DDS Extension\) on page 723](#) discuss the other threads that are created by *Connexth*.

A record in the database can be deleted only when no threads are using it. *Connexth* uses a thread that periodically checks the database if records that have been marked for deletion can be removed. This period is set by **cleanup\_period**. When a *DomainParticipant* is being destroyed, the thread will wake up faster at the **shutdown\_cleanup\_period** as other threads delete and release records in preparation for shutting down.

On Windows and VxWorks® systems, the thread that is destroying the *DomainParticipant* may block up to **shutdown\_timeout** seconds while waiting for the database thread to finish removing all records and terminating. On other operating systems, the thread destroying the *DomainParticipant* will block as long as required for the database thread to terminate.

The default values for those and the rest of the parameters in this QosPolicy should be sufficient for most applications.

### 44.1.1 Example

The priority of the database thread should be set to the lowest priority among all threads in a real-time system. Although, the database thread should not be permitted to starve, the work that it performs is non-time-critical.

### 44.1.2 Properties

This QosPolicy cannot be modified after the *DomainParticipant* is created.

It can be set differently on the publishing and subscribing sides.

### 44.1.3 Related QosPolicies

- [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 714](#)
- [44.5 EVENT QosPolicy \(DDS Extension\) on page 721](#)
- [44.6 RECEIVER\\_POOL QosPolicy \(DDS Extension\) on page 723](#)

### 44.1.4 Applicable DDS Entities

- [16.3 DomainParticipants on page 81](#)

### 44.1.5 System Resource Considerations

Setting the thread parameters correctly on a real-time operating system is usually critical to the proper overall functionality of the applications on that system. Larger values for the `thread.stack_size`

parameter will use up more memory.

Smaller values for the `cleanup_period` and `shutdown_cleanup_period` will cause the database thread to wake up more frequently using more CPU.

*Connex* is permitted to use up more memory for larger values of `max_skiplist_level` and `max_weak_references`. Whether or not more memory is actually used depends on actual operating conditions.

## 44.2 DISCOVERY QoSPolicy (DDS Extension)

The DISCOVERY QoS configures how *DomainParticipants* discover each other on the network. It identifies where on the network this application can potentially discover other applications with which to communicate. The middleware will periodically send network packets to these locations, announcing itself to any remote applications that may be present, and will listen for announcements from those applications. The discovery process is described in detail in [Discovery Overview \(Chapter 22 on page 309\)](#).

This QoSPolicy includes the members in [Table 44.2 DDS\\_DiscoveryQoSPolicy](#). For defaults and valid ranges, please refer to the API Reference HTML documentation.

**Table 44.2 DDS\_DiscoveryQoSPolicy**

Type	Field Name	Description
DDS_StringSeq	<code>enabled_transports</code>	Transports available for use by the discovery process. See <a href="#">44.2.1 Transports Used for Discovery below</a> .
DDS_StringSeq	<code>initial_peers</code>	Unicast locators (address/indices) of potential participants with which this <i>DomainParticipant</i> will attempt to establish communications. See <a href="#">44.2.2 Setting the 'Initial Peers' List on the next page</a> .
DDS_StringSeq	<code>multicast_receive_addresses</code>	List of multicast addresses on which Discovery-related messages can be received by the <i>DomainParticipant</i> . See <a href="#">44.2.4 Configuring Multicast Receive Addresses on page 701</a> .
DDS_Long	<code>metatraffic_transport_priority</code>	Transport priority to be used for sending Discovery messages. See <a href="#">44.2.5 Meta-Traffic Transport Priority on page 701</a> .
DDS_Boolean	<code>accept_unknown_peers</code>	Whether to accept a participant discovered via unicast that is not in the <code>initial_peers</code> list. See <a href="#">44.2.6 Controlling Acceptance of Unknown Peers on page 701</a> .
DDS_Boolean	<code>enable_endpoint_discovery</code>	Whether endpoint discovery will automatically occur with discovered <i>DomainParticipants</i> . See <a href="#">27.5 Supervising Endpoint Discovery on page 356</a> .

### 44.2.1 Transports Used for Discovery

The `enabled_transports` field allows you to specify the set of installed and enabled transports that can be used to discover other *DomainParticipants*. This field is a sequence of strings where each string specifies an alias of a registered (and thus installed and enabled) transport. Please see the API Reference HTML documentation (select **Modules**, **RTI Connex API Reference**, **Pluggable Transports**) for more information.

## 44.2.2 Setting the ‘Initial Peers’ List

When a *DomainParticipant* is created, it needs to find other participants in the same DDS domain—this is known as the ‘discovery process’ which is discussed in [Discovery Overview \(Chapter 22 on page 309\)](#). One way to do so is to use this QosPolicy to specify a list of potential participants. This is the role of the parameter `initial_peers`. The strings containing peer descriptors are stored in the `initial_peers` string sequence. The format of a string discussed in [24.1 Peer Descriptor Format on page 326](#).

The peers stored in `initial_peers` are merely *potential* peers—there is no requirement that the peer *DomainParticipants* are actually up and running or even will eventually exist. The *Connex* discovery process will try to contact all potential peer participants in the list periodically using unicast transports (as configured by the [44.3 DISCOVERY\\_CONFIG QosPolicy \(DDS Extension\) on page 703](#)).

The `initial_peers` parameter can be modified in source code or it can be initialized from an environment variable, `NDDS_DISCOVERY_PEERS` or from a text file, see [Chapter 24 Configuring the Peers List Used in Discovery on page 324](#).

Some transports accept the use of hostnames to specify the initial peers. By default, *Connex* only resolves those hostnames when the *DomainParticipant* is created, but the DNS tracker can be used to keep the IP addresses of these hostnames updated. See [26.3 Using DNS Tracker to Keep Peer List Updated on page 350](#).

## 44.2.3 Adding and Removing Peers List Entries

The *DomainParticipant*’s `add_peer()` operation adds a peer description to the internal peer list that was initialized by the `initial_peer` field of the `DISCOVERY` QosPolicy.

```
DDS_ReturnCode_t DDSDomainParticipant::add_peer (
    const char* peer_desc)
```

The `peer_desc` string must be formatted as specified in [24.1 Peer Descriptor Format on page 326](#).

You can call this operation any time after the *DomainParticipant* has been enabled. An attempt will be made to contact the new peer immediately.

Adding peers with this operation has no effect on the `initial_peers` list. After a *DomainParticipant* has been created, the contents of the `initial_peers` field merely shows what the internal peer list was initialized to be. Therefore, `initial_peers` may not reflect the actual potential peer list used by a *DomainParticipant*. Furthermore, if you call `get_qos()`, the returned list of peers will not include the added peer—`get_qos()` will only show you what is set in the **`initial_peers`** list.

A peer added with `add_peer()` is *not* considered to be “unknown.” (That is, you may have **`accept_unknown_peers`** ([44.2.6 Controlling Acceptance of Unknown Peers on the next page](#)) set to `FALSE` and still use `add_peer()`.)

This behavior may change depending on the DNS tracker configuration; see [26.3 Using DNS Tracker to Keep Peer List Updated on page 350](#). Adding a peer with a hostname that cannot be resolved into an IP address will produce an error if the DNS Tracker has not been enabled for that *DomainParticipant*.

You can remove an entry from the list with `remove_peer()`. Note that `remove_peer()` is only supported if Simple Participant Discovery (see [22.1 Simple Participant Discovery on page 310](#)) is enabled for the Participant.

You can ignore data from a participant by using the `ignore_participant()` operation described in [Chapter 27 Restricting Communication—Ignoring Entities on page 352](#).

## 44.2.4 Configuring Multicast Receive Addresses

The `multicast_receive_addresses` field in the `DISCOVERY` QosPolicy is a sequence of strings that specifies a set of multicast group addresses on which the *DomainParticipant* will listen for discovery meta-traffic. Each string must have a valid multicast address in either IPv4 dot notation or IPv6 presentation format. Please look at publicly available documentation of the IPv4 and IPv6 standards for the definition and valid address ranges for multicast.

The `multicast_receive_addresses` field can be initialized from multicast addresses that appear in the `NDDS_DISCOVERY_PEERS` environment variable or text file, see [Chapter 24 Configuring the Peers List Used in Discovery on page 324](#). A multicast address found in the environment variable or text file will be added both to the `initial_peers` and `multicast_receive_addresses` fields. Note that the addresses in `initial_peers` are ones in which the *DomainParticipant* will *send* discovery meta-traffic, and the ones in `multicast_receive_addresses` are used for *receiving* discovery meta-traffic.

If `NDDS_DISCOVERY_PEERS` does *not* contain a multicast address, then `multicast_receive_addresses` is cleared and the RTI discovery process will not listen for discovery messages via multicast.

If `NDDS_DISCOVERY_PEERS` contains one or more multicast addresses, the addresses are stored in `multicast_receive_addresses`, starting at element 0. They will be stored in the order in which they appear in `NDDS_DISCOVERY_PEERS`.

**Note:** Currently, *Connex* will only listen for discovery traffic on the first multicast address (element 0) in `multicast_receive_addresses`.

If you want to send discovery meta-traffic on a different set of multicast addresses than you want to receive discovery meta-traffic, set `initial_peers` and `multicast_receive_addresses` via the QosPolicy API.

## 44.2.5 Meta-Traffic Transport Priority

The `metatraffic_transport_priority` field is used to specify the transport priority to be used for sending all discovery meta-traffic. See the [47.26 TRANSPORT\\_PRIORITY QosPolicy on page 856](#) for details on how transport priorities may be used.

## 44.2.6 Controlling Acceptance of Unknown Peers

The `accept_unknown_peers` field controls whether or not a *DomainParticipant* is allowed to communicate with other *DomainParticipants* found via unicast transport that are not in its peers list (which

is the combination of the **initial\_peers** list and any peers added with the **add\_peer()** operation described in [44.2.3 Adding and Removing Peers List Entries on page 700](#)).

Suppose Participant A is included in Participant B's initial peers list, but Participant B is not in Participant A's list. When Participant B contacts Participant A by sending it a unicast discovery packet, then Participant A has a choice:

- If **accept\_unknown\_peers** is `DDS_BOOLEAN_TRUE`, then Participant A will reply to Participant B, and communications will be established.
- If **accept\_unknown\_peers** is `DDS_BOOLEAN_FALSE`, then Participant A will ignore Participant B, and A and B will never talk.

Note that Participants do not exchange peer lists. So if Participant A knows about Participant B, and Participant B knows about Participant C, Participant A will not discover Participant C.

**Note:** If **accept\_unknown\_peers** is false and shared memory is disabled, applications on the same node will not communicate if only 'localhost' is specified in the peer list. If shared memory is disabled or 'shmem://' is not specified in the peer list, if you want to communicate with other applications on the same node through the loopback interface, you must put the actual node address or hostname in **NDDS\_DISCOVERY\_PEERS**.

## 44.2.7 Example

You will always use this policy to set the `participant_id` when you want to run more than one *DomainParticipant* in the same DDS domain on the same host.

The easiest way to set the initial peers list is to use the `NDDS_DISCOVERY_PEERS` environment variable. However, should you want asymmetric multicast addresses for sending or receiving meta-traffic, you will need to use this `QosPolicy` directly.

A reason to use asymmetric multicast addresses is to take advantage of the efficiency provided by using multicast, while at the same time preventing all participants from discovering each other. For example, suppose you have a system in which you have a single server node and a hundred client nodes. The client nodes do not publish or subscribe to each other's data and thus never need to know about each others existence.

If we did not use multicast, we would have to populate the server application's peer list with 100 peer descriptors for each of the client nodes. Each client application would only need to have the server application in its peer list. The maintenance of the list is unwieldy, especially if nodes are constantly reconfigured and addresses changed. In addition, the server will send out discovery packets on a per client basis since the peer list essentially holds 100 unicast addresses.

Instead, if we used a single multicast address in the `NDDS_DISCOVERY_PEERS` environment variable, the server and all of the clients would discover each other. Certainly, the list is easier to maintain,

but the total amount of traffic has actually increased since the clients are now exchanging packets with each other uselessly.

To keep the list maintainable, as well as to minimize discovery traffic, we can have the server send out packets on a multicast address by modifying its *initial\_peer* field. The clients would have their **multicast\_receive\_addresses** field set to the same address used by the server. The **initial\_peers** of the clients would only need the single unicast peer descriptor of the server as before.

Now, the server can send a single packet that will be received by all of the clients, but the clients will not discover each other because they never send out a multicast packet themselves.

## 44.2.8 Properties

This QosPolicy cannot be modified after the *DomainParticipant* is created.

It can be set differently on the publishing and subscribing sides.

## 44.2.9 Related QosPolicies

- [44.3 DISCOVERY\\_CONFIG QosPolicy \(DDS Extension\)](#) below
- [44.7 TRANSPORT\\_BUILTIN QosPolicy \(DDS Extension\)](#) on page 725

## 44.2.10 Applicable Entities

- [16.3 DomainParticipants](#) on page 81

## 44.2.11 System Resource Considerations

For every entry in the **initial\_peers** list, *Connex*t will periodically send a discovery packet to see if that participant exists. If the list has many potential participants that are never started, then CPU and network bandwidth may be wasted in sending out packets that will never be received.

## 44.3 DISCOVERY\_CONFIG QosPolicy (DDS Extension)

The DISCOVERY\_CONFIG QosPolicy is used to tune the discovery process. It controls how often to send discovery packets, how to determine when participants are alive or dead, and resources used by the discovery mechanism.

The amount of network traffic required by the discovery process can vary widely based on how your application has chosen to configure the middleware's network addressing (unicast vs. multicast, multicast TTL, etc.), the size of the system, whether all applications are started at the same time or whether start times are staggered, and other factors. Your application can use this policy to make trade-offs between discovery completion time and network bandwidth utilization. In addition, you can introduce random back-off periods into the discovery process to decrease the probability of network contention when many applications start simultaneously.

This QosPolicy includes the members in [Table 44.3 DDS\\_DiscoveryConfigQosPolicy](#). Many of these members are described in [Discovery Overview \(Chapter 22 on page 309\)](#). For defaults and valid ranges, please refer to the API Reference HTML documentation.

**Table 44.3 DDS\_DiscoveryConfigQosPolicy**

Type	Field Name	Description
DDS_Duration_t	participant_liveliness_lease_duration	The time period after which other DomainParticipants can consider this one dead if they do not receive a liveliness packet from this DomainParticipant.
DDS_Duration_t	participant_liveliness_assert_period	<p>The period of time at which this DomainParticipant will send out packets asserting that it is alive.</p> <p>When using SPDP (<a href="#">22.1 Simple Participant Discovery on page 310</a>), the message sent at this period serves two purposes: to assert a participant's liveliness and to announce a participant to potential new peers. These messages are full participant announcements containing all information needed for participant discovery to complete.</p> <p>When using SPDP2 (<a href="#">22.2 (Experimental) Simple Participant Discovery 2.0 on page 311</a>), this field only configures the period at which small liveliness messages are sent. These messages contain only the information needed for a participant to identify another remote participant. The <b>participant_announcement_period</b> configures how often participant announcement messages are sent for the purpose of discovering new peers.</p>
DDS_RemoteParticipantPurgeKind	remote_participant_purge_kind	Controls the DomainParticipant's behavior for purging records of remote participants (and their contained entities) with which discovery communication has been lost. See <a href="#">44.3.2 Controlling Purging of Remote Participants on page 712</a> .
DDS_Duration_t	max_liveliness_loss_detection_period	The maximum amount of time between when a remote entity stops maintaining its liveliness and when the matched local entity realizes that fact.
DDS_Long	initial_participant_announcements	Sets how many initial participant announcements the <i>DomainParticipant</i> will send to all initial peers when it is first enabled. They are sent at a random period between <b>min_initial_participant_announcement_period</b> and <b>max_initial_participant_announcement_period</b> .
DDS_Long	new_remote_participant_announcements	Sets how many participant announcements the DomainParticipant will send only to newly discovered participants after the <b>initial_participant_announcements</b> have completed. They are sent at a random period between <b>min_initial_participant_announcement_period</b> and <b>max_initial_participant_announcement_period</b> .
DDS_Duration_t	min_initial_participant_announcement_period	Sets the minimum and maximum times between participant announcements when sending <b>initial_participant_announcements</b> or <b>new_remote_participant_announcements</b> . These messages are sent with a period between them that is a random duration between <b>min_initial_participant_announcement_period</b> and <b>max_initial_participant_announcement_period</b> . This randomness reduces the chances of a network collision when multiple participants are started at the same time.
DDS_Duration_t	max_initial_participant_announcement_period	
DDS_Duration_t	participant_announcement_period	The period at which a participant announces itself to potential peers when using the <a href="#">22.2 (Experimental) Simple Participant Discovery 2.0 on page 311</a> (SPDP2). This field is not supported when using <a href="#">22.1 Simple Participant Discovery on page 310</a> ; in that case, <b>participant_liveliness_assert_period</b> should be used instead.

Table 44.3 DDS\_DiscoveryConfigQosPolicy

Type	Field Name	Description
<a href="#">Table 44.4 DDS_Built-inTopicReaderResourceLimits_t</a>	participant_reader_resource_limits	Configures the resource for the built-in DataReaders used to access discovery information; see <a href="#">44.3.1 Resource Limits for Builtin-Topic DataReaders on page 710</a> and <a href="#">Accessing Discovery Information through Built-In Topics (Chapter 28 on page 359)</a> .

<a href="#">Table 47.49 DDS_WriterDataLifecycleQosPolicy</a>	publication_writer_data_lifecycle	Configures writer data-lifecycle settings for a built-in publication writer. (DDS_WriterDataLifecycleQosPolicy::autodispose_unregistered_instances will always be TRUE.)
<a href="#">Table 47.14 DDS_RtpsReliableWriterProtocol_t</a>	subscription_writer	Configures the RTPS reliable protocol parameters for the writer side of a reliable connection. Built-in DataWriters send reliable discovery information to DomainParticipants that were dynamically discovered (see <a href="#">Discovery Overview (Chapter 22 on page 309)</a> ).
<a href="#">Table 47.49 DDS_WriterDataLifecycleQosPolicy</a>	subscription_writer_data_lifecycle	Configures writer data-lifecycle settings for a built-in subscription writer. (DDS_WriterDataLifecycleQosPolicy::autodispose_unregistered_instances will always be TRUE.)

Table 44.3 DDS\_DiscoveryConfigQosPolicy

Type	Field Name	Description
DDS_DiscoveryConfigBuiltinPluginKindMask	builtin_discovery_plugins	<p>The bit mask of available kinds for selecting builtin discovery plugins:</p> <ul style="list-style-type: none"> <li>• <b>(default)</b> DDS_DISCOVERYCONFIG_BUILTIN_SDP: Enables the builtin Simple Discovery Protocol, which consists of both the <a href="#">22.1 Simple Participant Discovery on page 310</a> (SPDP) and the <a href="#">22.3 Simple Endpoint Discovery on page 317</a> (SEDP).</li> <li>• DDS_DISCOVERYCONFIG_BUILTIN_SPDP: Enables only the <a href="#">22.1 Simple Participant Discovery on page 310</a>, which means that you intend to use a non-builtin alternative for endpoint discovery, such as Limited Bandwidth Endpoint Discovery (LBED).</li> <li>• (Experimental) DDS_DISCOVERYCONFIG_BUILTIN_SPDP2: Enables an experimental version of the Simple Participant Discovery Protocol that is designed for decreased bandwidth usage and improved reliability. See <a href="#">22.2 (Experimental) Simple Participant Discovery 2.0 on page 311</a> for more details. This participant discovery protocol must be enabled with an endpoint discovery plugin, such as the Simple Endpoint Discovery Protocol (SEDP).</li> </ul> <p><b>Note:</b> It is not valid to enable both SPDP and SPDP2 at the same time.</p> <ul style="list-style-type: none"> <li>• DDS_DISCOVERYCONFIG_BUILTIN_SEDP: Enables only the <a href="#">22.3 Simple Endpoint Discovery on page 317</a>, which means that you intend to use a non-builtin alternative for participant discovery, such as Limited Bandwidth Participant Discovery (LBPDP).</li> <li>• DDS_DISCOVERYCONFIG_BUILTIN_DPSE: Dynamic Participant discovery, Static Endpoint discovery (DPSE) enables SPDP for participant discovery and LBED for endpoint discovery. Using this value requires the Limited Bandwidth Endpoint Discovery (LBED) plug-in. See <a href="#">RTI Limited Bandwidth Endpoint Discovery Plugins User's Manual</a>.</li> <li>• DDS_DISCOVERYCONFIG_BUILTIN_PLUGIN_MASK_NONE: No builtin discovery is used. This setting should be used if you are replacing both endpoint and participant discovery algorithms with non-builtin alternatives. For example, MASK_NONE can be used when LBED and LBPDP are both (simultaneously) enabled via the Limited Bandwidth Plugins.</li> </ul>

Table 44.3 DDS\_DiscoveryConfigQosPolicy

Type	Field Name	Description
DDS_DiscoveryConfigBuiltinChannelKindMask	enabled_builtin_channels	<p>A bit mask specifying which builtin channels should be enabled.</p> <p>While there are a number of builtin channels that are used by <i>Connex</i>, the only built-in channel that can currently be enabled or disabled is the ServiceRequest channel. This channel is used by the locator reachability feature (see <a href="#">26.2 Detection of Unreachable Locators on page 350</a>) and TopicQuery feature (see <a href="#">Chapter 60 Topic Queries on page 1142</a>). If you are not using these features and wish to reduce network traffic and endpoint resource usage, you may disable the ServiceRequest channel with this field.</p> <p>The default value, DDS_DISCOVERYCONFIG_SERVICE_REQUEST_CHANNEL, enables the ServiceRequest channel, which is required by the TopicQuery and locator reachability features. Disabling the ServiceRequest channel reduces resource consumption including network bandwidth, CPU utilization, and memory. When the ServiceRequest channel is disabled, the TopicQuery and locator reachability features (which use the ServiceRequest channel) are disabled. Errors will be generated if you create a TopicQuery, enable TopicQuery dispatch, or enable locator reachability while the ServiceRequest channel is disabled.</p>
DDS_ReliabilityQosPolicyKind	participant_message_reader_reliability_kind	<p>Reliability kind configuration setting for a built-in participant message reader (default: best-effort).</p> <p>See <a href="#">Table 47.36 DDS_ReliabilityQosPolicy</a></p>
<a href="#">Table 48.2 DDS_RtpsReliableReaderProtocol_t</a>	participant_message_reader	RTPS protocol-related configuration settings for a built-in participant message reader.

<a href="#">Table 47.35 DDS_PublishModeQosPolicy</a>	publication_writer_publish_mode	Determines whether the Discovery built-in publication DataWriter publishes data synchronously or asynchronously and how.
<a href="#">Table 47.35 DDS_PublishModeQosPolicy</a>	subscription_writer_publish_mode	Determines whether the Discovery built-in subscription DataWriter publishes data synchronously or asynchronously and how.
<a href="#">Table 46.1 DDS_AsynchronousPublisherQosPolicy</a>	asynchronous_publisher	Asynchronous publishing settings for the Discovery Publisher and all entities that are created by it.
DDS_Duration_t	default_domain_announcement_period	<p>The period at which a participant will announce itself to the default DDS domain 0 using the default UDPv4 multicast group address for discovery traffic on that DDS domain.</p> <p>For DDS domain 0, the default discovery multicast address is 239.255.0.1:7400.</p> <p>To disable announcement to the default DDS domain, set this to DURATION_INFINITE.</p> <p>When this period is set to a value other than DURATION_INFINITE and <b>ignore_default_domain_announcements</b> (see below) is FALSE, you can get information about participants running in different DDS domains by creating a participant in DDS domain 0 and implementing the <b>on_data_available</b> callback (see <a href="#">40.7.1 DATA_AVAILABLE Status on page 627</a>) in the ParticipantBuiltinTopicData built-in DataReader's listener (see <a href="#">28.2 Built-in DataReaders on page 360</a>).</p> <p>You can learn the domain ID associated with a participant by looking at the <a href="#">domain_id on page 361</a> in the ParticipantBuiltinTopicData.</p>

Table 44.3 DDS\_DiscoveryConfigQosPolicy

Type	Field Name	Description
DDS_Boolean	ignore_default_domain_announcements	<p>When TRUE, ignores the announcements received by a participant on the default DDS domain 0 corresponding to participants running on domains IDs other than 0.</p> <p>This setting only applies to participants running on the default DDS domain 0 and using the default port mapping.</p> <p>When TRUE, a participant running on the default DDS domain 0 will ignore announcements from participants running on different DDS domain IDs.</p> <p>When FALSE, a participant running on the default DDS domain 0 will provide announcements from participants running on different DDS domain IDs to the application via the ParticipantBuiltinTopicData built-in DataReader (see <a href="#">28.2 Built-in DataReaders on page 360</a>).</p>
<a href="#">Table 47.14 DDS_RtpsReliableWriterProtocol_t</a>	service_request_writer	RTPS protocol-related configuration settings for the built-in service request writer.
<a href="#">Table 47.49 DDS_WriterDataLifecycleQosPolicy</a>	service_request_writer_data_lifecycle	Configures writer data-lifecycle settings for the built-in service request writer.
<a href="#">Table 47.35 DDS_PublishModeQosPolicy</a>	service_request_writer_publish_mode	Determines whether the Discovery built-in service request DataWriter publishes data synchronously or asynchronously and how.
<a href="#">Table 48.1 DDS_DataReaderProtocolQosPolicy</a>	service_request_reader	RTPS protocol-related configuration settings for the built-in service request reader.
DDS_Duration_t	locator_reachability_assert_period	<p>Configures the period at which this <i>DomainParticipant</i> will ping all the locators that it has discovered from other <i>DomainParticipants</i>.</p> <p>This period should be strictly less than <a href="#">locator_reachability_lease_duration below</a>.</p> <p>If <a href="#">locator_reachability_lease_duration below</a> is INFINITE, this parameter is ignored.</p> <p>The <i>DomainParticipant</i> will not assert remote locators.</p>
DDS_Duration_t	locator_reachability_lease_duration	<p>For the purpose of this explanation, we use 'local' to refer to the <i>DomainParticipant</i> in which we configure <a href="#">locator_reachability_lease_duration above</a> and 'remote' to refer to the other <i>DomainParticipants</i> communicating with the local <i>DomainParticipant</i>.</p> <p>This setting configures a timeout announced to the remote <i>DomainParticipants</i>.</p> <p>This timeout is used by the remote <i>DomainParticipants</i> as the maximum period by which a remote locator must be asserted by the local <i>DomainParticipant</i> (through a REACHABILITY PING message) before considering this locator as "unreachable" from the local <i>DomainParticipant</i>.</p> <p>When a remote <i>DomainParticipant</i> detects that one of its locators is not reachable from the local <i>DomainParticipant</i>, it will notify the local <i>DomainParticipant</i> of this event. From that moment on, and until notified otherwise, the local <i>DomainParticipant</i> will not send RTPS messages to remote <i>DomainParticipants</i> using this locator.</p> <p>If this value is set to INFINITE, the local <i>DomainParticipant</i> will send RTPS messages to a remote <i>DomainParticipant</i> on the locators announced by the remote <i>DomainParticipant</i>, regardless of whether or not the remote <i>DomainParticipant</i> can be reached using these locators.</p> <p>By default, this field is set to INFINITE, meaning that the locator reachability feature is not enabled. To enable this feature, set this field to a value other than INFINITE.</p>

Table 44.3 DDS\_DiscoveryConfigQosPolicy

Type	Field Name	Description
DDS_Duration_t	locator_reachability_change_detection_period	<p>Determines the maximum period at which this <i>DomainParticipant</i> will check to see if its locators are reachable from other <i>DomainParticipants</i> according to the other <i>DomainParticipants'</i> <a href="#">locator_reachability_lease_duration on the previous page</a>.</p> <p>If <a href="#">locator_reachability_lease_duration on the previous page</a> is INFINITE, this parameter is ignored.</p> <p>The <i>DomainParticipant</i> will not schedule an event to see if its locators are reachable from other <i>DomainParticipants</i>.</p>
<a href="#">Table 47.14 DDS_RtpsReliableWriterProtocol_t</a>	secure_volatile_writer	RTPS protocol-related configuration settings for the builtin Key Exchange writer.
<a href="#">Table 47.35 DDS_PublishModeQosPolicy</a>	secure_volatile_writer_publish_mode	<p>Publish mode policy for the builtin secure volatile writer.</p> <p>Determines whether the builtin secure volatile <i>DataWriter</i> publishes data synchronously or asynchronously and how.</p>
<a href="#">Table 48.2 DDS_RtpsReliableReaderProtocol_t</a>	secure_volatile_reader	RTPS protocol-related configuration settings for the builtin Key Exchange reader.
DDS_Long	endpoint_type_object_lb_serialization_threshold	<p>Minimum size (in bytes) of the serialized <i>TypeObject</i> that will trigger the serialization of a <i>TypeObjectLb</i> instead of the regular <i>TypeObject</i>. <i>TypeObjectLb</i> is a compressed version of the serialized <i>TypeObject</i>. This compressed version reduces the size needed to propagate a <i>TypeObject</i> as part of Simple Endpoint Discovery. For example, setting this policy to 1000 will trigger the serialization of the <i>TypeObjectLb</i> for <i>TypeObjects</i> whose serialized size is greater than 1000 Bytes.</p> <p>Range: [-1, 2147483647]. The sentinel value -1 disables <i>TypeObject</i> compression (by never sending <i>TypeObjectLb</i>). Any non-valid values will behave as 0.</p> <p>Default: 0 (<i>TypeObjectLb</i> is enabled by default)</p>
DDS_Duration_t	dns_tracker_polling_period	<p>Configures the frequency used by the DNS Tracker thread to query the DNS service.</p> <p>If this parameter is set to INFINITE, the DNS tracker is disabled and changes in hostnames will not be tracked.</p> <p>See <a href="#">26.3 Using DNS Tracker to Keep Peer List Updated on page 350</a> for more information.</p>

When a *DomainParticipant* is first enabled, it sends out **initial\_participant\_announcements** number of participant messages to the peers on its **initial\_peers** list. These messages are sent at a random time between **min\_initial\_participant\_announcement\_period**.

After a *DomainParticipant* has sent out **initial\_participant\_announcements**, it needs to send a message periodically to let other participants know that it is still alive as well as to discover new participants that may join the system. These messages are sent to all peers in the peer list that was initialized by the **initial\_peers** parameter of the [44.2 DISCOVERY QosPolicy \(DDS Extension\) on page 699](#) and to any peers that have been discovered that were not on the **initial\_peers** list (if **accept\_unknown\_peers** is true). The peer *DomainParticipants* that already know about this *DomainParticipant* will use the **participant\_liveliness\_lease\_duration** provided by this participant to declare the participant dead if they have not received a participant message for the specified time.

The **participant\_liveliness\_assert\_period** is the periodic rate at which this *DomainParticipant* will be sending periodic participant messages. Since these messages are not sent reliably and can get dropped by the transport, it is important to set:

$$\text{participant\_liveliness\_assert\_period} < \text{participant\_liveliness\_lease\_duration} / N$$

where N is the number of liveliness messages that other *DomainParticipants* must miss before they decide that this *DomainParticipant* is dead.

*DomainParticipants* that receive a participant message from a participant that they did not know about previously will have “discovered” the participant. When one *DomainParticipant* discovers another, the discoverer will immediately send its own participant messages back. **new\_remote\_participant\_announcements** controls how many of these messages are sent only to newly discovered participants, and **min/max\_initial\_participant\_announcement\_period** controls the time period in between each message.

For more information on the discovery process, see [Discovery Overview \(Chapter 22 on page 309\)](#).

### 44.3.1 Resource Limits for Builtin-Topic DataReaders

The `DDS_BuiltinTopicReaderResourceLimits_t` structure is shown in [Table 44.4 DDS\\_BuiltinTopicReaderResourceLimits\\_t](#). This structure contains several fields that are used to configure the resource limits of the builtin-topic *DataReaders* used to receive discovery meta-traffic from other *DomainParticipants*.

**Table 44.4 DDS\_BuiltinTopicReaderResourceLimits\_t**

Type	Field Name	Description
DDS_Long	initial_samples	Initial number of meta-traffic DDS data samples that can be stored by a builtin-topic <i>DataReader</i> .
	max_samples	Maximum number of meta-traffic DDS data samples that can be stored by a builtin-topic <i>DataReader</i> .
	initial_infos	Initial number of <code>DDS_SampleInfo</code> structures allocated for the builtin-topic <i>DataReader</i> .
	max_infos	Maximum number of <code>DDS_SampleInfo</code> structures that can be allocated for the built-in topic <i>DataReader</i> . <b>max_infos</b> must be $\geq$ <b>max_samples</b>
	initial_outstanding_reads	Initial number of times in which memory can be concurrently loaned via read/take calls on the builtin-topic <i>DataReader</i> without being returned with <code>return_loan()</code> .
	max_outstanding_reads	Maximum number of times in which memory can be concurrently loaned via read/take calls on the builtin-topic <i>DataReader</i> without being returned with <code>return_loan()</code> .
	max_samples_per_read	Maximum number of DDS samples that can be read/taken on a same built-in topic <i>DataReader</i> .
DDS_Boolean	disable_fragmentation_support	Determines whether the builtin-topic <i>DataReader</i> can receive fragmented DDS samples. When fragmentation support is not needed, disabling fragmentation support will save some memory resources.

Table 44.4 DDS\_BuiltinTopicReaderResourceLimits\_t

Type	Field Name	Description
DDS_Long	max_fragmented_samples	<p>The maximum number of DDS samples for which the <i>DataReader</i> may store fragments at a given point in time.</p> <p>At any given time, a <i>DataReader</i> may store fragments for up to <b>max_fragmented_samples</b> DDS samples while waiting for the remaining fragments. These DDS samples need not have consecutive sequence numbers and may have been sent by different <i>DataWriters</i>. Once all fragments of a DDS sample have been received, the DDS sample is treated as a regular DDS sample and becomes subject to standard QoS settings, such as max_samples. <i>Connex</i> will drop fragments if the max_fragmented_samples limit has been reached.</p> <p>For best-effort communication, <i>Connex</i> will accept a fragment for a new DDS sample, but drop the oldest fragmented DDS sample from the same remote writer.</p> <p>For reliable communication, <i>Connex</i> will drop fragments for any new DDS samples until all fragments for at least one older DDS sample from that writer have been received.</p> <p>Only applies if <b>disable_fragmentation_support</b> is FALSE.</p>
DDS_Long	initial_fragmented_samples	<p>The initial number of DDS samples for which a builtin-topic <i>DataReader</i> may store fragments.</p> <p>Only applies if <a href="#">disable_fragmentation_support on the previous page</a> is FALSE.</p>
DDS_Long	max_fragmented_samples_per_remote_writer	<p>The maximum number of DDS samples per remote writer for which a builtin-topic <i>DataReader</i> may store fragments.</p> <p>Logical limit so a single remote writer cannot consume all available resources.</p> <p>Only applies if <a href="#">disable_fragmentation_support on the previous page</a> is FALSE.</p>
DDS_Long	max_fragments_per_sample	<p>Maximum number of fragments for a single DDS sample.</p> <p>Only applies if <a href="#">disable_fragmentation_support on the previous page</a> is FALSE.</p>
DDS_Boolean	dynamically_allocate_fragmented_samples	<p>By default, the middleware does not allocate memory upfront, but instead allocates memory from the heap upon receiving the first fragment of a new sample. The amount of memory allocated equals the amount of memory needed to store all fragments in the sample. Once all fragments of a sample have been received, the sample is deserialized and stored in the regular receive queue. At that time, the dynamically allocated memory is freed again.</p> <p>This QoS setting is useful for large, but variable-sized data types where up-front memory allocation for multiple samples based on the maximum possible sample size may be expensive. The main disadvantage of not pre-allocating memory is that one can no longer guarantee the middleware will have sufficient resources at run-time.</p> <p>If dynamically_allocate_fragmented_samples is FALSE, the middleware will allocate memory up-front for storing fragments for up to initial_fragmented_samples samples. This memory may grow up to max_fragmented_samples if needed.</p> <p>Only applies if <a href="#">disable_fragmentation_support on the previous page</a> is FALSE.</p>

There are builtin-topics for exchanging data about *DomainParticipants*, for publications (*Publisher/DataWriter* combination) and for subscriptions (*Subscriber/DataReader* combination). The *DataReaders* for the publication and subscription builtin-topics are reliable. The *DataReader* for the participant builtin-topic is best effort.

You can set listeners on these *DataReaders* that are created automatically when a *DomainParticipant* is created. With these listeners, your code can be notified when remote *DomainParticipants*, *Publishers/DataWriters*, and *Subscriber/DataReaders* are discovered. You can always check the receive queues of those *DataReaders* for the same information about discovered entities at any time. Please see [Accessing Discovery Information through Built-In Topics \(Chapter 28 on page 359\)](#) for more details.

The **initial\_samples** and **max\_samples**, and related **initial\_infos** and **max\_infos**, fields size the amount of declaration messages can be stored in each builtin-topic *DataReader*.

## 44.3.2 Controlling Purging of Remote Participants

When discovery communication with a remote participant has been lost, the local participant must make a decision about whether to continue attempting to communicate with that participant and its contained entities. The **remote\_participant\_purge\_kind** is used to select the desired behavior.

This does not pertain to the situation in which a remote participant has been gracefully deleted and notification of that deletion has been successfully received by its peers. In that case, the local participant will immediately stop attempting to communicate with those entities and will remove the associated remote entity records from its internal database.

The **remote\_participant\_purge\_kind** can be set to the following values:

### **DDS\_LIVELINESS\_BASED\_REMOTE\_PARTICIPANT\_PURGE**

This value causes *Connex*t to keep the state of a remote participant and its contained entities for as long as the participant maintains its liveliness contract (as specified by its **participant\_liveliness\_lease\_duration** in the [44.3 DISCOVERY\\_CONFIG QosPolicy \(DDS Extension\) on page 703](#)).

A participant will maintain its own liveliness to any remote participant via inter-participant liveliness traffic (see [47.15 LIVELINESS QosPolicy on page 825](#)).

The default Simple Discovery Protocol described in [Discovery Overview \(Chapter 22 on page 309\)](#) automatically maintains this liveliness, whereas other discovery mechanisms may or may not.

### **DDS\_NO\_REMOTE\_PARTICIPANT\_PURGE**

With this value, *Connex*t will never purge the records of a remote participant with which discovery communication has been lost.

- If the remote participant is later rediscovered, the records that remain in the database will be re-used.
- If the remote participant is not rediscovered, the records will continue to take up space in the database for as long as the local participant remains in existence.

In most cases, you will *not* need to change this value from its default, **DDS\_LIVELINESS\_BASED\_REMOTE\_PARTICIPANT\_PURGE**.

However, **DDS\_NO\_REMOTE\_PARTICIPANT\_PURGE** may be a good choice if the following conditions apply:

Discovery communication with a remote participant may be lost while data communication remains intact. This will not be the typical case if discovery takes place over the Simple Discovery Protocol.

Extensive and prolonged lack of discovery communication between participants is not expected to be common, either because loss of the participant will be rare, or because participants may be lost sporadically but will typically return again.

Maintaining inter-participant liveness is problematic, perhaps because a participant has no writers with the appropriate [47.15 LIVELINESS QosPolicy on page 825](#) kind.

### 44.3.3 Controlling the Reliable Protocol Used by Builtin-Topic DataWriters/DataReaders

The connection between the *DataWriters* and *DataReaders* for the publication and subscription builtin-topics are reliable. The `publication_writer`, `subscription_writer`, `publication_reader`, and `subscription_reader` parameters of the [44.3 DISCOVERY\\_CONFIG QosPolicy \(DDS Extension\) on page 703](#) configure the reliable messaging protocol used by *Connex* for those topics. *Connex*'s reliable messaging protocol is discussed in [Reliability Models for Sending Data \(Chapter 32 on page 446\)](#).

See also:

- [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 788](#)
- [48.1 DATA\\_READER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 871](#).

### 44.3.4 Example

Users will be most interested in setting the `participant_liveness_lease_duration` and `participant_liveness_assert_period` values for their *DomainParticipants*. Basically, the lease duration governs how fast an application realizes another application dies unexpectedly. The shorter the periods, the quicker a *DomainParticipant* can determine that a remote participant is dead and act accordingly by declaring all of the remote *DataWriters* and *DataReaders* of that participant dead as well.

However, you should realize that the shorter the period the more liveness packets will sent by the *DomainParticipant*. How many packets is also determined by the number of peers in the peer list of the participant—whether or not the peers on the list are actually alive.

### 44.3.5 Properties

This QosPolicy cannot be modified after the *DomainParticipant* is created.

It can be set differently on the publishing and subscribing sides.

### 44.3.6 Related QosPolicies

- [44.2 DISCOVERY QosPolicy \(DDS Extension\) on page 699](#)
- [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on the next page](#)

- [44.9 WIRE\\_PROTOCOL QosPolicy \(DDS Extension\) on page 730](#)
- [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 788](#)
- [48.1 DATA\\_READER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 871](#)
- [48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 876](#)

### 44.3.7 Applicable DDS Entities

- [16.3 DomainParticipants on page 81](#)

### 44.3.8 System Resource Considerations

Setting smaller values for time periods can increase the CPU and network bandwidth usage. Setting larger values for maximum limits can increase the maximum memory that *Connex* may allocate for a *DomainParticipant* while increasing the initial values will increase the initial memory allocated for a *DomainParticipant*.

## 44.4 DOMAIN\_PARTICIPANT\_RESOURCE\_LIMITS QosPolicy (DDS Extension)

The `DOMAIN_PARTICIPANT_RESOURCE_LIMITS` QosPolicy includes various settings that configure how *DomainParticipants* allocate and use physical memory for internal resources, including the maximum sizes of various properties.

This QosPolicy sets maximum size limits on variable-length parameters used by the participant and its contained *Entities*. It also controls the initial and maximum sizes of data structures used by the participant to store information about locally-created and remotely-discovered entities (such as *DataWriters/DataReaders*), as well as parameters used by the internal database to size the hash tables used by the data structures.

By default, a *DomainParticipant* is allowed to dynamically allocate memory as needed as users create local *Entities* such as *DataWriters* and *DataReaders* or as the participant discovers new applications to store their information. By setting fixed values for the maximum parameters in this QosPolicy, you can bound the memory that can be allocated by a *DomainParticipant*. In addition, by setting the initial values to the maximum values, you can reduce the amount of memory allocated by *DomainParticipants* after the initialization period. Notice that memory can still be allocated dynamically after the initialization period. For example, when a new local *DataWriter* or *DataReader* is created, the initial memory required for its queue is allocated dynamically.

The maximum sizes of several variable-length parameters—such as the number of partitions that can be stored in the [46.5 PARTITION QosPolicy on page 751](#), the maximum length of data store in the [47.30 USER\\_DATA QosPolicy on page 864](#) and [46.4 GROUP\\_DATA QosPolicy on page 748](#), and many others—can be changed from their defaults using this QoS. However, it is important that all *DomainParticipants* that need to communicate with each other use the same set of maximum values. Otherwise,

when these parameters are propagated from one *DomainParticipant* to another, a *DomainParticipant* with a smaller maximum length may reject the parameter resulting in an error.

This QosPolicy includes the members in [Table 44.5 DDS\\_DomainParticipantResourceLimitsQosPolicy](#). For defaults and valid ranges, please refer to the API Reference HTML documentation.

**Table 44.5 DDS\_DomainParticipantResourceLimitsQosPolicy**

Type	Field Name	Description
DDS_AllocationSettings_t (see description column)	local_writer_allocation	Each allocation structure configures how many objects of each type, <object>_allocation, will be allocated by the <i>DomainParticipant</i> . DDS_Long	flow_controller_hash_buckets	See above row
DDS_Long	max_gather_destinations	Configures the maximum number of destinations that a message can be addressed in a single network send operation. Can improve efficiency if the underlying transport support can send to multiple destinations.
DDS_Long	participant_user_data_max_length	Controls the maximum lengths of <a href="#">47.30 USER_DATA QosPolicy on page 864</a> , <a href="#">45.1 TOPIC_DATA QosPolicy on page 737</a> and <a href="#">46.4 GROUP_DATA QosPolicy on page 748</a> for different entities. Must be configured to be the same values on all <i>DomainParticipants</i> in the same DDS domain.
DDS_Long	topic_data_max_length	See above row
DDS_Long	publisher_group_data_max_length	See above row
DDS_Long	subscriber_group_data_max_length	See above row
DDS_Long	writer_user_data_max_length	See above row

Table 44.5 DDS\_DomainParticipantResourceLimitsQosPolicy

Type	Field Name	Description
DDS_Long	reader_user_data_max_length	See above row
DDS_Long	max_partitions	Controls the maximum number of partitions that can be assigned to a Publisher or Subscriber with the <a href="#">46.5 PARTITION QosPolicy on page 751</a> . Must be configured to be the same value on all <i>DomainParticipants</i> in the same DDS domain.
DDS_Long	max_partition_cumulative_characters	Controls the maximum number of combined characters among all partition names in the <a href="#">46.5 PARTITION QosPolicy on page 751</a> . Must be configured to be the same value on all <i>DomainParticipants</i> in the same DDS domain.
DDS_Long	type_code_max_serialized_length	Maximum size of serialized string for type code. If your data type has an especially complex type code, you may need to increase this value. See <a href="#">17.7 Using Generated Types without Connex (Standalone) on page 234</a> . <b>Note:</b> TypeObject is now the standard method of exchanging type information in <i>Connex</i> , so <code>type_code_max_serialized_length</code> defaults to 0 bytes. It is recommended to use <code>type_object_max_serialized_length</code> to configure the maximum serialized size for the TypeObject describing the type.
DDS_Long	type_object_max_serialized_length	Maximum length, in bytes, that the buffer to serialize TypeObject can consume. This parameter limits the size of the TypeObject that a <i>DomainParticipant</i> is able to propagate. Since TypeObjects contain all of the information of a data structure, including the strings that define the names of the members of a structure, complex data-structures can result in TypeObjects larger than the default maximum. This field allows you to specify a larger value. Cannot be unlimited.
DDS_Long	type_object_max_deserialized_length	Maximum number of bytes that a deserialized TypeObject can consume. This parameter limits the size of the TypeObject that a <i>DomainParticipant</i> is able to store.
DDS_Long	serialized_type_object_dynamic_allocation_threshold	Threshold, in bytes, for dynamic memory allocation for the serialized typeObject. Above this threshold, the memory for a TypeObject is allocated dynamically. Below it, the memory is obtained from a pool of fixed-size buffers. If <code>type_object_max_serialized_length</code> is not <code>LENGTH_UNLIMITED</code> and is smaller than <code>serialized_type_object_dynamic_allocation_threshold</code> , then <code>serialized_type_object_dynamic_allocation_threshold</code> will be adjusted to <code>type_object_max_serialized_length</code> and a warning will be logged. By default, <code>serialized_type_object_dynamic_allocation_threshold</code> is the same value as <code>type_object_max_serialized_length</code> , 8192. This means that the typeObject memory is obtained from a pool of fixed-size buffers.
DDS_Long	deserialized_type_object_dynamic_allocation_threshold	Threshold, in bytes, for dynamic memory allocation for the deserialized TypeObject. Above this threshold, the memory for a TypeObject is allocated dynamically. Below it, the memory is obtained from a pool of fixed-size buffers. The size of the buffers is equal to this threshold. If <code>type_object_max_deserialized_length</code> is not <code>LENGTH_UNLIMITED</code> and is smaller than <code>deserialized_type_object_dynamic_allocation_threshold</code> , then <code>deserialized_type_object_dynamic_allocation_threshold</code> will be adjusted to <code>type_object_max_deserialized_length</code> and a warning will be logged.
DDS_Long	contentfilter_property_max_length	Maximum length of all data related to <a href="#">18.3 ContentFilteredTopics on page 256</a> .
DDS_Long	channel_seq_max_length	Maximum number of channels that can be specified in a <i>DataWriter's</i> <a href="#">47.16 MULTI_CHANNEL QosPolicy (DDS Extension) on page 830</a> .

Table 44.5 DDS\_DomainParticipantResourceLimitsQosPolicy

Type	Field Name	Description
DDS_Long	channel_filter_expression_max_length	Maximum length of a channel filter_expression in a <i>DataWriter's</i> <a href="#">47.16 MULTI_CHANNEL QosPolicy (DDS Extension) on page 830</a> .
DDS_Long	participant_property_list_max_length	Maximum number of properties ((name, value) pairs) that can be stored in the <i>DomainParticipant's</i> <a href="#">47.19 PROPERTY QosPolicy (DDS Extension) on page 837</a> .
DDS_Long	participant_property_string_max_length	Maximum cumulative length (in bytes, including the null terminating characters) of all the (name, value) pairs in a <i>DomainParticipant's</i> Property QosPolicy.
DDS_Long	writer_property_list_max_length	Maximum number of properties ((name, value) pairs) that can be stored in a <i>DataWriter's</i> Property QosPolicy.
DDS_Long	writer_property_string_max_length	Maximum cumulative length (in bytes, including the null terminating characters) of all the (name, value) pairs in a <i>DataWriter's</i> Property QosPolicy.
DDS_Long	reader_property_list_max_length	Maximum number of properties ((name, value) pairs) that can be stored in a <i>DataReader's</i> Property QosPolicy.
DDS_Long	reader_property_string_max_length	Maximum cumulative length (in bytes, including the null terminating characters) of all the (name, value) pairs in a <i>DataReader's</i> Property QosPolicy.
DDS_Long	max_endpoint_groups	Maximum number of endpoint groups allowed in an <a href="#">48.1 DATA_READER_PROTOCOL QosPolicy (DDS Extension) on page 871</a> .
	max_endpoint_group_cumulative_characters	Maximum number of combined <b>role_name</b> characters allowed in all endpoint groups in an <a href="#">47.1 AVAILABILITY QosPolicy (DDS Extension) on page 769</a> . The maximum number of combined characters should account for a terminating NULL ("") character for each <b>role_name</b> string.
DDS_Long	transport_info_list_max_length	<p>When sending <i>DomainParticipant</i> discovery information, this value defines the maximum number of transports whose properties will be announced to other <i>DomainParticipants</i>.</p> <p>If a <i>DomainParticipant</i> has three transports installed and this value is two, the <i>DomainParticipant</i> will only announce information about the first two transports. When receiving <i>DomainParticipant</i> information, this value defines the maximum size of the list containing information about the transports installed in a remote <i>DomainParticipant</i>. The information about the transports installed in a <i>DomainParticipant</i> is made available to remote <i>DomainParticipants</i> through the sequence field transport_info in the Participant Built-in Topic's Data (see <a href="#">Table 28.1 Participant Built-in Topic's Data Type (DDS_ParticipantBuiltinTopicData)</a>)</p> <p>Setting this value to 0 disables the capability of <i>Connex</i>t to detect and report transport misconfigurations. However, it does not affect the capability of reaching a given <i>DomainParticipant</i> in all transports available on that <i>DomainParticipant</i>.</p>
DDS_AllocationSettings_t	remote_topic_query_allocation	<p>Allocation settings applied to remote TopicQueries.</p> <p>These settings are applied to the allocation of information about TopicQueries created by other participants and discovered by this participant. When the participant receives a new topic query that would make the current count go above <b>max_count</b>, it is not processed until the current count drops (i.e. another topic query is canceled). The topic query stays in the Built-in ServiceRequest DataReader queue until it can be processed or it is canceled.</p>
DDS_Long	remote_topic_query_hash_buckets	Number of hash buckets for remote TopicQueries.
DDS_Long	writer_data_tag_list_max_length	Maximum number of data tags ((name, value) pairs) that can be stored in a <i>DataWriter's</i> DataTag QosPolicy.
DDS_Long	writer_data_tag_string_max_length	Maximum cumulative length (in bytes, including the null terminating characters) of all the (name, value) pairs in a <i>DataWriter's</i> DataTag QosPolicy.

**Table 44.5 DDS\_DomainParticipantResourceLimitsQosPolicy**

Type	Field Name	Description
DDS_Long	reader_data_tag_list_max_length	Maximum number of data tags ((name, value) pairs) that can be stored in a <i>DataReader's</i> DataTag QosPolicy.
DDS_Long	reader_data_tag_string_max_length	Maximum cumulative length (in bytes, including the null terminating characters) of all the (name, value) pairs in a <i>DataReader's</i> DataTag QosPolicy.
DDS_UnsignedLong	shmem_ref_transfer_mode_max_segments	Sets the maximum number of shared memory segments that can be created by all <i>DataWriters</i> belonging to this participant if you are using Zero Copy transfer over shared memory. See <a href="#">34.1.5 Zero Copy Transfer Over Shared Memory on page 516</a> .

Most of the parameters for this QosPolicy are described in the Description column of the table. However, you may need to refer to the sections listed in the column to fully understand the context in which the parameter is used.

An important parameter in this QosPolicy that is often changed by users is the **type\_object\_max\_serialized\_length**. This parameter limits the size of the TypeObject that a *DomainParticipant* is able to store and propagate for user data types. TypeObjects are the wire representation for a type code. Type codes can be used by external applications to understand user data types without having the data type predefined in compiled form. However, since type codes contain all of the information of a data structure, including the strings that define the names of the members of a structure, complex data structures can result in TypeObjects larger than the default maximum of 8192 bytes. Thus it is common for users to set this parameter to a larger value. However, as with all parameters in this QosPolicy defining maximum sizes for variable-length elements, all *DomainParticipants* should set the same value for **type\_object\_max\_serialized\_length**.

The <object type> hash\_buckets configure the hash-table data structure that is used to efficiently search the database. The optimal number of buckets depend on the actual number of objects that will be stored in the hash table. So if you know how many *DataWriters* will be created in a *DomainParticipant*, you may change the value of local\_writer\_hash\_buckets to balance memory usage against search efficiency. A smaller value will use up less memory, but a larger value will make database lookups for the object more efficient.

If you modify any of the <entity type>\_data\_max\_length, max\_partitions, or max\_partition\_cumulative\_characters parameters, then you must make sure that they are modified to be the same value for all *DomainParticipants* in the same DDS domain for all applications. If they are different and an application sends data that is larger than another application is configured to hold, then the two *Entities*, whether a matching *DataWriter/DataReader* pair or even two *DomainParticipants* will fail to connect.

#### 44.4.1 Configuring Resource Limits for Asynchronous DataWriters

When using an asynchronous *Publisher*, if a call to **write()** is blocked due to a resource limit, the block will last until the timeout period expires, which will prevent others from freeing the resource. To avoid this situation, make sure that the *DomainParticipant's* **resource\_limits.outstanding\_asynchronous\_**

**sample\_allocation** is always greater than the sum of all asynchronous *DataWriters*' **resource\_limits.max\_samples** (see [47.22 RESOURCE\\_LIMITS QosPolicy](#) on page 850).

## 44.4.2 Configuring Memory Allocation

The `<object type>_allocation` configures the number of `<object type>`'s that can be stored in the internal *Connex*t database. For example, `local_writer_allocation` configures how many local *DataWriters* can be created for the *DomainParticipant*.

The `DDS_AllocationSettings_t` structure sets the initial and maximum number of each object type that can be stored. The **initial\_count** will determine how many objects are initially allocated, and **max\_count** will determine the maximum amount of objects that *Connex*t is allowed to allocate. The **incremental\_count** is used to allocate more objects in chunks when the number of objects created exceed the **initial\_count**. You can use fixed-size increments or -1 to double the amount of extra memory allocated each time memory is needed.

Notice that the memory pre-allocated for an object using the `DDS_AllocationSettings_t` structure is not the full memory that will be required by the object during its lifecycle. Memory can still be allocated dynamically when the object is actually used. For example, when a new local *DataWriter* or *DataReader* is created, the memory required for its queue is allocated from the heap dynamically at the moment of creation, independently of the `DDS_AllocationSettings_t` value. The memory pre-allocated for the object by using the `DDS_AllocationSettings_t` structure only accounts for the memory required to store the object in the internal in-memory database, not its full state.

You should only modify these parameters if you want to decrease the initial memory used by *Connex*t when a *DomainParticipant* is created or you want to increase the maximum number of local and remote *Entities* that can be stored in a *DomainParticipant*.

## 44.4.3 Example

For most applications, the default values for this QosPolicy may be sufficient. However, if an application uses the `PARTITION`, `USER_DATA`, `TOPIC_DATA`, or `GROUP_DATA` QosPolicies, the default maximum sizes of the data associated with those policies may need to be adjusted as required by the application. As noted previously, you must make sure that all *DomainParticipants* in the same DDS domain use the same sets of values or it is possible that *Connex*t will not successfully connect two *Entities*.

## 44.4.4 Properties

This QosPolicy cannot be modified after the *DomainParticipant* is created.

It can be set differently on the publishing and subscribing sides.

## 44.4.5 Related QosPolicies

- [44.1 DATABASE QosPolicy \(DDS Extension\) on page 696](#)
- [44.3 DISCOVERY\\_CONFIG QosPolicy \(DDS Extension\) on page 703](#)

- [46.5 PARTITION QosPolicy on page 751](#)
- [47.19 PROPERTY QosPolicy \(DDS Extension\) on page 837](#)

## 44.4.6 Applicable DDS Entities

- [16.3 DomainParticipants on page 81](#)

## 44.4.7 System Resource Considerations

Memory and CPU usage are directly affected by the values set for parameters of this QosPolicy. See the detailed descriptions above for specifics.

## 44.5 EVENT QosPolicy (DDS Extension)

The EVENT QosPolicy configures the internal *Connex* Event thread.

This QoS allows the you to configure thread properties such as priority level and stack size. You can also configure the maximum number of events that can be posted to the event thread. It contains the members in [Table 44.6 DDS\\_EventQoS Policy](#). For defaults and valid ranges, please refer to the API Reference HTML documentation.

Table 44.6 DDS\_EventQoSPolicy

Type	Field Name	Description
DDS_ThreadSettings_t	thread.mask thread.priority thread.stack_size	Thread settings for the event thread used by <i>Connex</i> to wake up for a timed event and possibly execute listener callbacks. The values used for these settings are OS-dependent; see the <a href="#">RTI Connex Core Libraries Platform Notes</a> for details. Note: thread.cpu_list and thread.cpu_rotation are not relevant in this QoS policy.
DDS_Long	initial_count	Initial number of events that can be stored simultaneously.
DDS_Long	max_count	Maximum number of events that can be stored simultaneously.

The Event thread is used to wake up and execute timed events posted to the event queue. In a *DomainParticipant*, different Entities may have constraints that have to be checked at periodic intervals or at specific times. If the constraint is violated, a callback function may need to be executed. Timed events include checking for timeouts and deadlines, and executing internal and user timeout or exception handling routines/callbacks. A combination of a time, constraint, and callback can be considered to be an event. For more information, see [Chapter 65 Event Thread on page 1185](#).

For example, a *DataReader* may have a constraint that requires data to be received within a period of time specified by the [47.7 DEADLINE QoS Policy on page 804](#). For that *DataReader*, an event is stored by the Event thread so that it will wake up periodically to check to see if data has arrived in time. If not, the Event thread will execute the `on_requested_deadline_missed()` *Listener* callback of the *DataReader* (if it was installed and enabled).

A reliable connection between a *DataWriter* and *DataReader* will also post events for sending heartbeats used in the reliable protocol discussed in [Reliability Models for Sending Data \(Chapter 32 on page 446\)](#).

This QoS configures the parameters associated with thread creation as well as the number of events that can be simultaneously stored by the Event thread.

### 44.5.1 Example

In a real-time operating system, the priority of the Event thread should be set relative to the priority of the events that it must handle. For example, you may want the Event thread to have a high priority if the deadlines and callbacks that it handles are time or safety critical. It may be critical that the data of a particular *DataReader* arrives on time or if not, alternative action is taken with minimal latency.

If you create many *Entities* in a *DomainParticipant* with QoS Policies that will post events that check deadlines, liveness or send heartbeats, then you may need to increase the maximum number of events that can be stored by the Event thread.

If your application is sending a lot of reliable data, you should increase the event thread priority to be higher than the sending thread priority.

## 44.5.2 Properties

This QosPolicy cannot be modified after the *DomainParticipant* is created.

It can be set differently on the publishing and subscribing sides.

## 44.5.3 Related QosPolicies

- [44.1 DATABASE QosPolicy \(DDS Extension\) on page 696](#)
- [44.6 RECEIVER\\_POOL QosPolicy \(DDS Extension\) below](#)

## 44.5.4 Applicable DDS Entities

- [16.3 DomainParticipants on page 81](#)

## 44.5.5 System Resource Considerations

Increasing **initial\_count** and **max\_count** will increase initial and maximum memory used for storing events.

Setting the thread parameters correctly on a real-time operating system is usually critical to the proper overall functionality of the applications on that system. Larger values for the thread.**stack\_size** parameter will use up more memory.

By default, a *DomainParticipant* will dynamically allocate memory as needed for events posted to the event thread. However, by setting a maximum value or setting the initial and maximum value to be the same, you can either bound the amount of memory allocated for the event thread or prevent a *DomainParticipant* from dynamically allocating memory for the event thread after initialization.

## 44.6 RECEIVER\_POOL QosPolicy (DDS Extension)

The RECEIVER\_POOL QosPolicy configures the internal *Connex* thread used to process the data received from a transport. The Receive thread is described in detail in [Chapter 66 Receive Threads on page 1187](#).

This QosPolicy contains the members in [Table 44.7 DDS\\_ReceiverPoolQoSPolicy](#).

Table 44.7 DDS\_ReceiverPoolQoSPolicy

Type	Field Name	Description
struct DDS_ThreadSettings_t	thread.mask thread.priority thread.stack_size hread.cpu_list thread.cpu_rotation	Thread settings for the receive thread(s) used by <i>Connex</i> t to process data received from a transport. The values used for these settings are OS-dependent; see the <a href="#">RTI Connex</a> t Core Libraries Platform Notes for details.  See also: <a href="#">Chapter 68 Controlling CPU Core Affinity for RTI Threads</a> on page 1191.
DDS_Long	buffer_size	Size of the receive buffer in bytes.  The receive buffer is used by the receive thread to store the raw data that arrives over the transports in non-zero-copy transports.  Zero-copy transports do not copy their data into the buffer provided by the receive thread. Instead, they provide the receive thread data in buffers allocated by the transports themselves. Only the shared memory built-in transport (SHMEM) supports zero-copy.  <b>buffer_size</b> must always be at least as large as the maximum <b>message_size_max</b> across <i>all</i> of the transports being used that are not doing zero-copy.  By default, the <b>buffer_size</b> is AUTO (e.g., DDS_LENGTH_AUTO in C/C++), which is equal to the maximum <b>message_size_max</b> across <i>all</i> of the non-zero-copy transports. You may want the value to be greater than the default if you try to limit the largest data packet that can be sent through the transport(s) in one application, but you still want to receive data from other applications that have not made the same change.  For example, to avoid IP fragmentation, you may want to set the <b>message_size_max</b> for IP-based transports to a small value, such as 1400 bytes. However, you may not be able to apply this change to all the applications at the same time. To receive data from these other applications, the <b>buffer_size</b> should be equal to the original <b>message_size_max</b> for the transport.  For information on the valid range, see the API Reference HTML documentation.
DDS_Long	buffer_alignment	Byte-alignment of the receive buffer. For the default and valid range, see the API Reference HTML documentation.

This QoSPolicy sets the thread properties, like priority level and stack size, for the threads used to receive and process data from transports. *Connex*t uses a separate receive thread per port per transport plugin. To force *Connex*t to use a separate thread to process the data for a *DataReader*, you should set a unique port for the [47.28 TRANSPORT\\_UNICAST QoSPolicy \(DDS Extension\)](#) on page 859 or [48.5 TRANSPORT\\_MULTICAST QoSPolicy \(DDS Extension\)](#) on page 891 for the *DataReader*.

*Connex*t creates at least one thread for every transport that is installed and enabled for use by the *DomainParticipant* for receiving data. These threads are used to process data DDS samples received for the participant's *DataReaders*, as well as messages used by *Connex*t itself in support of the application discovery process discussed in [Discovery Overview \(Chapter 22 on page 309\)](#).

The user application may configure *Connex*t to create many more threads for receiving data sent via multicast or even to dedicate a thread to process the DDS data samples of a single *DataReader* received on a particular transport. This QoSPolicy is used in the creation of all receive threads.

## 44.6.1 Example

When new data arrives on a transport, the receive thread may invoke the `on_data_available()` of the *Listener* callback of a *DataReader*. Thus, you may want to adjust the priority of the receive threads with respect to the other threads in the application as appropriate for the proper operation of the system.

## 44.6.2 Properties

This QoS Policy cannot be modified after the *DomainParticipant* is created.

It can be set differently on the publishing and subscribing sides.

## 44.6.3 Related QoS Policies

- [44.1 DATABASE QoS Policy \(DDS Extension\) on page 696](#)
- [44.5 EVENT QoS Policy \(DDS Extension\) on page 721](#)

## 44.6.4 Applicable DDS Entities

- [16.3 DomainParticipants on page 81](#)

## 44.6.5 System Resource Considerations

Increasing the `buffer_size` will increase memory used by a receive thread.

Setting the thread parameters correctly on a real-time operating system is usually critical to the proper overall functionality of the applications on that system. Larger values for the `thread_stack_size` parameter will use up more memory.

## 44.7 TRANSPORT\_BUILTIN QoS Policy (DDS Extension)

*Connex* comes with three different transport plugins built into the core libraries (for most supported target platforms). These are plugins for UDPv4, shared memory (SHMEM), and UDPv6. (If you've installed *RTI Real-Time WAN Transport*, UDPv4\_WAN is also available.)

This QoS Policy allows you to control which builtin transport plugins are used by a *DomainParticipant*. By default, only the UDPv4 and shared memory plugins are enabled (for most platforms; on some platforms, the shared memory plugin is not available). You can disable one or all of the builtin transports.

In some cases, users will disable the shared memory transport when they do not want applications to use shared memory to communicate when running on the same node.

This QoS Policy contains the member in [Table 44.8 DDS\\_TransportBuiltinQoS Policy](#). For the default and valid values, please refer to the API Reference HTML documentation (select **Modules**, **RTI Connex API Reference**, **QoS Policies**, **TRANSPORT\_BUILTIN**).

**Table 44.8 DDS\_TransportBuiltinQosPolicy**

Type	Field Name	Description
DDS_TransportBuiltinKindMask	mask	<p>A mask with bits that indicate which builtin transports will be installed. Three different transport plug-ins are built into the core <i>Connex</i>t libraries (for most supported target platforms): SHMEM, UDPv4, and UDPv6. (If you've installed <a href="#">Chapter 52 RTI Real-Time WAN Transport on page 986</a>, UDPv4_WAN is also available.)</p> <p>By default, the mask is set to SHMEM   UDPv4. Transports that are not in the mask will be disabled. MASK_NONE disables all the builtin transports.</p>

You can set the mask programmatically or via XML. For example, programmatically:

```
participant_qos.transport_builtin.mask = DDS_TRANSPORTBUILTIN_UDPv4 | DDS_TRANSPORTBUILTIN_SHMEM;
```

Via XML, you can use the <transport\_builtin> tags. For example:

```
<domain_participant_qos>
  <transport_builtin>
    <mask>UDPv4</mask>
  </transport_builtin>
</domain_participant_qos>
```

In XML only, you can additionally configure the builtin transport properties, such as <message\_size\_max>. See [50.4.6 Transport Properties on page 936](#).

**Note:** Currently, *Connex*t will only listen for discovery traffic on the first multicast address (element 0) in **multicast\_receive\_addresses**.

## 44.7.1 Example

See [44.7.5 System Resource Considerations on the next page](#) for an example of why you may want to use this QosPolicy.

In addition, customers may wish to install and use their own custom transport plugins instead of any of the builtin transports. In that case, this QosPolicy may be used to disable all builtin transports.

## 44.7.2 Properties

This QosPolicy cannot be modified after the *DomainParticipant* is created.

It can be set differently on the publishing and subscribing sides.

## 44.7.3 Related QosPolicies

- [47.27 TRANSPORT\\_SELECTION QosPolicy \(DDS Extension\) on page 858](#)
- [47.28 TRANSPORT\\_UNICAST QosPolicy \(DDS Extension\) on page 859](#)

- [48.5 TRANSPORT\\_MULTICAST QosPolicy \(DDS Extension\) on page 891](#)

## 44.7.4 Applicable DDS Entities

- [16.3 DomainParticipants on page 81](#)

## 44.7.5 System Resource Considerations

You can save memory and other system resources if you disable the builtin transports that your application will not use. For example, if you only run a single application with a single *DomainParticipant* on each machine in your network, then you can disable the shared memory transport since your applications will never use it to send or receive messages.

## 44.8 TRANSPORT\_MULTICAST\_MAPPING QosPolicy (DDS Extension)

The multicast address on which a *DataReader* wants to receive its data can be explicitly configured using the [48.5 TRANSPORT\\_MULTICAST QosPolicy \(DDS Extension\) on page 891](#). However in systems with many multicast addresses, managing the multicast configuration can become cumbersome. The *TransportMulticastMapping* QosPolicy is designed to make configuration and assignment of the *DataReader's* multicast addresses more manageable. When using this QosPolicy, the middleware will automatically assign a multicast receive address for a *DataReader* from a range by using configurable mapping rules.

*DataReaders* can be assigned a single multicast receive address using the rules defined in this QosPolicy on the *DomainParticipant*. This multicast receive address is exchanged during simple discovery in the same manner used when the multicast receive address is defined explicitly. No additional configuration on the writer side is needed.

Mapping within a range is done through a mapping function. The middleware provides a default hash (md5) mapping function. This interface is also pluggable, so you can specify a custom mapping function to minimize collisions.

To use this QosPolicy, you must set the **kind** in the [48.5 TRANSPORT\\_MULTICAST QosPolicy \(DDS Extension\) on page 891](#) to AUTOMATIC.

This QosPolicy contains the member in [Table 44.9 DDS\\_TransportMulticastMappingQosPolicy](#).

Table 44.9 DDS\_TransportMulticastMappingQosPolicy

Type	Field Name	Description
DDS_TransportMappingSettingsSeq	value	A sequence of multicast communication settings, each of which has the format shown in <a href="#">Table 44.10 DDS_TransportMulticastSettings_t</a> .

Table 44.10 DDS\_TransportMulticastSettings\_t

Type	Field Name	Description
char *	addresses	A string containing a comma-separated list of IP addresses or IP address ranges to be used to receive multicast traffic for the entity with a topic that matches the <b>topic_expression</b> . See <a href="#">44.8.1 Formatting Rules for Addresses</a> below.
char *	topic_expression	A regular expression used to map topic names to corresponding addresses. See <a href="#">35.5.5 SQL Extension: Regular Expression Matching</a> on page 560.
DDS_TransportMulticastMappingFunction_t	mapping_function	<i>Optional.</i> Defines a user-provided pluggable mapping function. See <a href="#">Table 44.11 DDS_TransportMulticastMappingFunction_t</a> .

Table 44.11 DDS\_TransportMulticastMappingFunction\_t

Type	Field Name	Description
char *	dll	Specifies a dynamic library that contains a mapping function. You may specify a relative or absolute path. If the name is specified as "foo", the library name on Linux systems will be <b>libfoo.so</b> ; on Windows systems it will be <b>foo.dll</b> .
char *	function_name	Specifies the name of a mapping function in the library specified in the above <b>dll</b> . The function must implement the following interface: <pre>int function(const char* topic_name, int numberOfAddresses);</pre> The function must return an integer that indicates the <i>index</i> of the address to use for the given <b>topic_name</b> . For example, if the first address in the list should be used, it must return 0; if the second address in the list should be used, it must return 1, etc.

## 44.8.1 Formatting Rules for Addresses

- The string must contain IPv4 or IPv6 addresses separated by commas. For example:  
"239.255.100.1,239.255.100.2,239.255.100.3"

- You may specify ranges of addresses by enclosing the start and end addresses in square brackets. For example: "[239.255.100.1,239.255.100.3]".
- You may combine the two approaches. For example: "239.255.200.1,[239.255.100.1,239.255.100.3], 239.255.200.3"
- IPv4 addresses must be specified in Dot-decimal notation.
- IPv6 addresses must be specified using 8 groups of 16-bit hexadecimal values separated by colons. For example: FF00:0000:0000:0000:0202:B3FF:FE1E:8329.
- Leading zeroes can be skipped. For example: FF00:0:0:0:202:B3FF:FE1E:8329.
- You may replace a consecutive number of zeroes with a double colon, but only once within an address. For example: FF00::202:B3FF:FE1E:8329.

## 44.8.2 Example

This QoS policy configures the multicast ranges and mapping rules at the *DomainParticipant* level. You can configure a large set of multicast addresses on the *DomainParticipant*.

In addition, you can configure a mapping between topic names and multicast addresses. For example, topic "A" can be assigned to address 239.255.1.1 and topic "B" can be assigned to address 239.255.1.2.

This configuration is quite flexible. For example, you can specify mappings between a subset of topics to a range of multicast addresses. For example, topics "X", "Y" and "Z" can be mapped to [239.255.1.1, 239.255.1.255], or using regular expressions, "X\*" and "B-Z" can be mapped to a sub-range of addresses. See [35.5.5 SQL Extension: Regular Expression Matching on page 560](#).

## 44.8.3 Properties

This QosPolicy cannot be modified after the *DomainParticipant* is created.

## 44.8.4 Related QosPolicies

- [48.5 TRANSPORT\\_MULTICAST QosPolicy \(DDS Extension\) on page 891](#)

## 44.8.5 Applicable DDS Entities

- [16.3 DomainParticipants on page 81](#)

## 44.8.6 System Resource Considerations

See [48.5.5 System Resource Considerations on page 894](#).

## 44.9 WIRE\_PROTOCOL QosPolicy (DDS Extension)

The WIRE\_PROTOCOL QosPolicy configures some global Real-Time Publish Subscribe (RTPS) protocol-related properties for the *DomainParticipant*. The RTPS OMG-standard, interoperability protocol is used by *Connex*t to format and interpret messages between *DomainParticipants*.

It includes the members in [Table 44.12 DDS\\_WireProtocolQosPolicy](#). For defaults and valid ranges, please refer to the API Reference HTML documentation. (The default values contain the correctly initialized wire protocol attributes. They should not be modified without an understanding of the underlying Real-Time Publish Subscribe (RTPS) wire protocol.)

**Table 44.12 DDS\_WireProtocolQosPolicy**

Type	Field Name	Description
DDS_Long	participant_id	Unique identifier for participants that belong to the same DDS domain on the same host. See <a href="#">44.9.1 Choosing Participant IDs</a> below.
DDS_UnsignedLong	rtps_host_id	A machine/OS-specific host ID, unique in the DDS domain. See <a href="#">44.9.3 Controlling How the GUID is Set (rtps_auto_id_kind)</a> on page 732.
	rtps_app_id	A participant-specific ID, unique within the scope of the rtps_host_id. See <a href="#">44.9.3 Controlling How the GUID is Set (rtps_auto_id_kind)</a> on page 732.
	rtps_instance_id	An instance-specific ID of the <i>DomainParticipant</i> that, together with the rtps_app_id, is unique within the scope of the rtps_host_id. See <a href="#">44.9.3 Controlling How the GUID is Set (rtps_auto_id_kind)</a> on page 732.
DDS_RtpsWellKnownPorts_t	rtps_well_known_ports	Determines the well-known multicast and unicast ports for discovery and user traffic. See <a href="#">44.9.2 Ports Used for Discovery</a> on page 732.
DDS_RtpsReservedPortKindMask	rtps_reserved_ports_mask	Specifies which well-known multicast and unicast ports to reserve when enabling the <i>DomainParticipant</i> .
DDS_WireProtocolQosPolicyAutoKind	rtps_auto_id_kind	Kind of auto mechanism used to calculate the GUID prefix.
DDS_Boolean	compute_crc	Adds an RTPS CRC submessage to every message.
DDS_Boolean	check_crc	Checks if the received RTPS message is valid by comparing the computed CRC with the received RTPS CRC submessage.

Note that [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\)](#) on page 788 and [48.1 DATA\\_READER\\_PROTOCOL QosPolicy \(DDS Extension\)](#) on page 871 configure RTPS and reliability properties on a per *DataWriter* and *DataReader* basis.

### 44.9.1 Choosing Participant IDs

When you create a *DomainParticipant*, you must specify a domain ID, which identifies the communication channel across the whole system. Each *DomainParticipant* in the same DDS domain on the

same host also needs a unique integer, known as the **participant\_id**.

The **participant\_id** uniquely identifies a *DomainParticipant* from other *DomainParticipants* in the same DDS domain on the same host. You can use the same **participant\_id** value for *DomainParticipants* in the same DDS domain but running on different hosts.

The **participant\_id** is also used to calculate the default unicast user-traffic and the unicast meta-traffic port numbers, as described in [Chapter 23 Ports Used for Discovery on page 319](#). If you only have one *DomainParticipant* in the same DDS domain on the same host, you will not need to modify this value.

You can either allow *Connex*t to select a participant ID automatically (by setting **participant\_id** to -1), or choose a specific participant ID (by setting **participant\_id** to the desired value).

- **Automatic Participant ID Selection**

The default value of `participant_id` is -1, which means *Connex*t will select a participant ID for you.

*Connex*t will pick the smallest participant ID, based on the unicast ports available on the transports enabled for discovery, based on the unicast and/or multicast ports available on the transports enabled for discovery and/or user traffic.

The `rtps_reserved_ports_mask` field determines which ports to check when picking the next available participant ID. The reserved ports are calculated based on the formula specified in [23.1 Inbound Ports for Meta-Traffic on page 321](#) and [23.2 Inbound Ports for User Traffic on page 321](#). By default, *Connex*t will reserve the meta-traffic unicast port, the meta-traffic multicast port, and the user traffic unicast port.

*Connex*t will attempt to resolve an automatic port ID either when a *DomainParticipant* is enabled, or when a *DataReader* or a *DataWriter* is created. Therefore, all the transports enabled for discovery must have been registered by this time. Otherwise, the discovery transports registered after resolving the automatic port index may produce port conflicts when the *DomainParticipant* is enabled.

To see what value *Connex*t has selected, either:

- Change the verbosity level of the `NDDS_CONFIG_LOG_CATEGORY_API` category to `NDDS_CONFIG_LOG_VERBOSITY_STATUS_LOCAL` (see [54.2 Configuring Connex Logging on page 1089](#)).
- Call `get_qos()` and look at the `participant_id` value in the [44.9 WIRE\\_PROTOCOL QosPolicy \(DDS Extension\) on the previous page](#) after the *DomainParticipant* is enabled.

- **Manual Participant ID Selection**

If you do have multiple *DomainParticipants* on the same host, you should use consecutively numbered participant indices start from 0. This will make it easier to specify the discovery peers

using the **initial\_peers** parameter of this QoSPolicy or the `NDDS_DISCOVERY_PEERS` environment variable. See [Chapter 24 Configuring the Peers List Used in Discovery on page 324](#) for more information.

Do not use random participant indices since this would make DISCOVERY incredibly difficult to configure. In addition, the **participant\_id** has a maximum value of 120 (and will be less for domain IDs other than 0) when using an IP-based transport since the **participant\_id** is used to create the port number (see [Chapter 23 Ports Used for Discovery on page 319](#)), and for IP, a port number cannot be larger than 65536.

For details, see [Chapter 23 Ports Used for Discovery on page 319](#).

## 44.9.2 Ports Used for Discovery

The `rtps_well_known_ports` structure allows you to configure the ports that are used for discovery of inbound meta-traffic (discovery data internal to *Connex*) and user traffic (from your application).

It includes the members in [Table 44.13 DDS\\_RtpsWellKnownPorts\\_t](#). For defaults and valid ranges, please refer to the API Reference HTML documentation.

**Table 44.13 DDS\_RtpsWellKnownPorts\_t**

Type	Field Name	Description
DDS_ Long	port_base	The base port offset. All mapped well-known ports are offset by this value. Resulting ports must be within the range imposed by the underlying transport.
	domain_id_gain	Tunable gain parameters. See <a href="#">Chapter 23 Ports Used for Discovery on page 319</a> .
	participant_id_gain	
	builtin_multicast_port_offset	Additional offset for meta-traffic port. See <a href="#">23.1 Inbound Ports for Meta-Traffic on page 321</a> .
	builtin_unicast_port_offset	
	user_multicast_port_offset	Additional offset for user traffic port. See <a href="#">23.2 Inbound Ports for User Traffic on page 321</a> .
	user_unicast_port_offset	

## 44.9.3 Controlling How the GUID is Set (rtps\_auto\_id\_kind)

In order for the discovery process to work correctly, each *DomainParticipant* must have a unique identifier. This QoS policy specifies how that identifier should be generated.

RTPS defines a 96-bit prefix to this identifier; each *DomainParticipant* must have a unique value of this prefix relative to all other participants in its DDS domain.

If an application dies unexpectedly and is restarted, the IDs used by the new instance of *DomainParticipants* should be different than the ones used by the previous instances. A change in these values allows other *DomainParticipants* to know that they are communicating with a new instance of an application, and not the previous instance.

For legacy reasons, *Connex* divides the 96-bit prefix into three integers:

- The first integer is called **host ID**. The original purpose of this integer was to contain the identity of the machine on which the *DomainParticipant* is executing.
- The second integer is called an **application ID**. The original purpose of this integer was to contain a value that identifies the process or task in which the *DomainParticipant* is contained.
- The third integer is called **instance ID**. The original purpose was to contain a value that uniquely identifies a *DomainParticipant* within a task or process.

The `rtps_auto_id_kind` field can be used to configure the algorithm that *Connex* uses to populate the 96-bit prefix. Then you can optionally overwrite specific parts of the 96-bit prefix by explicitly configuring the `rtps_host_id` (first integer), `rtps_app_id` (second integer), and `rtps_instance_id` (third integer).

The `rtps_auto_id_kind` field supports three different prefix generation algorithms:

1. In the default and most common scenario, `rtps_auto_id_kind` is set to `RTPS_AUTO_ID_FROM_UUID`. As the name suggests, this mechanism uses a unique, randomly generated UUID to fill the `rtps_host_id`, `rtps_app_id`, or `rtps_instance_id` fields. The first two bytes of the `rtps_host_id` are replaced with the RTI vendor ID (0x0101).
2. (Legacy) When `rtps_auto_id_kind` is set to `DDS_RTPS_AUTO_ID_FROM_IP`, the 96-bit prefix is generated as follows:
  - `rtps_host_id`: the 32 bit value of the IPv4 of the first up and running interface of the host machine is assigned. If the host does not have an IPv4 address, the host-id will be automatically set to 0x7F000001.
  - `rtps_app_id`: the process (or task) ID is assigned.
  - `rtps_instance_id`: A counter is assigned that is incremented per new participant within a process.

`DDS_RTPS_AUTO_ID_FROM_IP` is not a good algorithm to guarantee prefix uniqueness, because the process ID can be recycled by the OSs. See [44.9.3.2 Uniqueness Problem with DDS\\_RTPS\\_AUTO\\_ID\\_FROM\\_IP and DDS\\_RTPS\\_AUTO\\_ID\\_FROM\\_MAC on page 735](#) for additional information.

3. (Legacy) When `rtps_auto_id_kind` is set to `DDS_RTPS_AUTO_ID_FROM_MAC`, the 96-bit prefix is generated as follows:

- **rtps\_host\_id**: the first 32 bits of the MAC address of the first up and running interface of the host machine are assigned.
- **rtps\_app\_id**: the last 32 bits of the MAC address of the first up and running interface of the host machine are assigned.
- **rtps\_instance\_id**: this field is split into two different parts. The process (or task) ID is assigned to the first 24 bits. A counter is assigned to the last 8 bits. This counter is incremented per new participant. In both scenarios, you can change the value of each field independently.

DDS\_RTSPS\_AUTO\_ID\_FROM\_IP is not a good algorithm to guarantee prefix uniqueness because the process ID can be recycled by the OSs. See [44.9.3.2 Uniqueness Problem with DDS\\_RTSPS\\_AUTO\\_ID\\_FROM\\_IP and DDS\\_RTSPS\\_AUTO\\_ID\\_FROM\\_MAC on the next page](#) for additional information.

### 44.9.3.1 Overwriting the Default RTPS 96-bit Prefix

Some examples are provided to better explain the behavior of this QoS Policy in case you want to change the default behavior with DDS\_RTSPS\_AUTO\_ID\_FROM\_MAC.

1. Get the *DomainParticipant* QoS from the *DomainParticipantFactory*:

```
DDS_DomainParticipantFactory_get_default_participant_qos(
    DDS_DomainParticipantFactory_get_instance(),
    &participant_qos);
```

2. Change the *WireProtocolQoSPolicy* using one of the following options.

- Use DDS\_RTSPS\_AUTO\_ID\_FROM\_MAC to explicitly set just the application/task identifier portion of the **rtps\_instance\_id** field:

```
participant_qos.wire_protocol.rtps_auto_id_kind =
    DDS_RTSPS_AUTO_ID_FROM_MAC;
participant_qos.wire_protocol.rtps_host_id =
    DDS_RTSPS_AUTO_ID;
participant_qos.wire_protocol.rtps_app_id =
    DDS_RTSPS_AUTO_ID;
participant_qos.wire_protocol.rtps_instance_id =
    (/* App ID */ (12 << 8) |
     /* Instance ID*/ (DDS_RTSPS_AUTO_ID));
```

- Only set the per participant counter and let *Connex*t handle the application/task identifier:

```

participant_qos.wire_protocol.rtps_auto_id_kind =
    DDS_RTTPS_AUTO_ID_FROM_MAC;
participant_qos.wire_protocol.rtps_host_id =
    DDS_RTTPS_AUTO_ID;
participant_qos.wire_protocol.rtps_app_id =
    DDS_RTTPS_AUTO_ID;
participant_qos.wire_protocol.rtps_instance_id =
    ( /* App ID */ (DDS_RTTPS_AUTO_ID) |
      /* Instance ID*/ (12));

```

- Set the entire **rtps\_instance\_id** field yourself:

```

participant_qos.wire_protocol.rtps_auto_id_kind =
    DDS_RTTPS_AUTO_ID_FROM_MAC;
participant_qos.wire_protocol.rtps_host_id =
    DDS_RTTPS_AUTO_ID;
participant_qos.wire_protocol.rtps_app_id =
    DDS_RTTPS_AUTO_ID;
participant_qos.wire_protocol.rtps_instance_id =
    ( /* App ID */ (12 << 8)) |
      /* Instance ID */ (9) )

```

**Note:** If you are using `DDS_RTTPS_AUTO_ID_FROM_MAC` as **rtps\_auto\_id\_kind** and you decide to manually handle the **rtps\_instance\_id** field, you must ensure that both parts are non-zero (otherwise *Connex*t will take responsibility for them).

RTI recommends that you always specify the two parts separately in order to avoid errors.

- Let *Connex*t handle the entire **rtps\_instance\_id** field:

```

participant_qos.wire_protocol.rtps_auto_id_kind =
    DDS_RTTPS_AUTO_ID_FROM_MAC;
participant_qos.wire_protocol.rtps_host_id =
    DDS_RTTPS_AUTO_ID;
participant_qos.wire_protocol.rtps_app_id =
    DDS_RTTPS_AUTO_ID;
participant_qos.wire_protocol.rtps_instance_id =
    DDS_RTTPS_AUTO_ID;

```

**Note:** If you are using `DDS_RTTPS_AUTO_ID_FROM_MAC` as **rtps\_auto\_id\_kind** and you decide to manually set the **rtps\_instance\_id** field, you must ensure that both parts are non-zero (otherwise *Connex*t will take responsibility for them). RTI recommends that you always specify the two parts separately in order to clearly show the difference.

3. Create the *DomainParticipant* as usual using the modified QoS structure instead of the default one.

#### 44.9.3.2 Uniqueness Problem with `DDS_RTTPS_AUTO_ID_FROM_IP` and `DDS_RTTPS_AUTO_ID_FROM_MAC`

This section applies only when **rtps\_auto\_id\_kind** is set to `DDS_RTTPS_AUTO_ID_FROM_IP` or `DDS_RTTPS_AUTO_ID_FROM_MAC`.

On many real-time operating systems, and even on some non-real-time operating systems, when a node is rebooted, and applications are automatically started, process IDs are deterministically assigned. That is, when the system restarts or if an application dies and is restarted, the application will be reassigned the same process or task ID.

This means that *Connex*'s automatic algorithm for creating unique **rtps\_app\_id**'s will produce the same value between sequential instances of the same application. This will confuse the other *DomainParticipants* on the network into thinking that they are communicating with the previous instance of the application instead of a new instance. Errors usually resulting in a failure to communicate will ensue.

Thus, for applications running on nodes that may be rebooted without letting the application shutdown appropriately (destroying the *DomainParticipant*), especially on nodes running real-time operating systems like VxWorks, you will want to set the **rtps\_app\_id** manually. We suggest that a strictly incrementing counter is stored either on a file system or in non-volatile RAM for the **rtps\_app\_id**.

Whatever method you use, you should make sure that the **rtps\_app\_id** is unique across all *DomainParticipants* running on a host as well as *DomainParticipants* that were recently running on the host. After a period configured through the [44.3 DISCOVERY\\_CONFIG QosPolicy \(DDS Extension\) on page 703](#), existing applications will eventually flush old *DomainParticipants* that did not properly shutdown from their databases. When that is done, then **rtps\_app\_id** may be reused.

## 44.9.4 Properties

This QosPolicy cannot be modified after the *DomainParticipant* is created.

If manually set, it must be set differently for every *DomainParticipant* in the same DDS domain across all applications. The value of **rtps\_app\_id** should also change between different invocations of the same application (for example, when an application is restarted).

## 44.9.5 Related QosPolicies

- [44.3 DISCOVERY\\_CONFIG QosPolicy \(DDS Extension\) on page 703](#)

## 44.9.6 Applicable DDS Entities

- [16.3 DomainParticipants on page 81](#)

## 44.9.7 System Resource Considerations

The use of this policy does not significantly impact the use of resources.

# Chapter 45 Topic QoS Policies

This section describes the only QoS Policy that strictly applies to *Topics* (and no other types of *Entities*)—the TOPIC\_DATA QoS Policy. For a complete list of the QoS Policies that can be set for *Topics*, see [Table 18.2 Topic QoS Policies](#).

Most of the QoS Policies that can be set on a *Topic* can also be set on the corresponding *DataWriter* and/or *DataReader*. The *Topic*'s QoS Policy is essentially just a place to store QoS settings that you plan to share with multiple entities that use that *Topic* (see how in [18.1.3 Setting Topic QoS Policies on page 250](#)); they are not used otherwise and are not propagated on the wire.

## 45.1 TOPIC\_DATA QoS Policy

This QoS Policy provides an area where your application can store additional information related to the *Topic*. This information is passed between applications during discovery (see [Discovery Overview \(Chapter 22 on page 309\)](#)) using builtin-topics (see [Accessing Discovery Information through Built-In Topics \(Chapter 28 on page 359\)](#)). How this information is used will be up to user code. *Connex*t does not do anything with the information stored as TOPIC\_DATA except to pass it to other applications. Use cases are usually application-to-application identification, authentication, authorization, and encryption purposes.

The value of the TOPIC\_DATA QoS Policy is sent to remote applications when they are first discovered, as well as when the *Topic*'s `set_qos()` method is called after changing the value of the TOPIC\_DATA. User code can set listeners on the builtin *DataReaders* of the builtin *Topics* used by *Connex*t to propagate discovery information. Methods in the builtin topic listeners will be called whenever new applications, *DataReaders*, and *DataWriters* are found. Within the user callback, you will have access to the TOPIC\_DATA that was set for the associated *Topic*.

Currently, TOPIC\_DATA of the associated *Topic* is only propagated with the information that declares a *DataWriter* or *DataReader*. Thus, you will need to access the value of TOPIC\_DATA through `DDS_PublicationBuiltinTopicData` or `DDS_SubscriptionBuiltinTopicData` (see [Accessing Discovery Information through Built-In Topics \(Chapter 28 on page 359\)](#)).

The structure for the `TOPIC_DATA` QosPolicy includes just one field, as seen in [Table 45.1 DDS\\_TopicDataQosPolicy](#). The field is a sequence of octets that translates to a contiguous buffer of bytes whose contents and length is set by the user. The maximum size for the data are set in the [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\)](#) on page 714.

**Table 45.1 DDS\_TopicDataQosPolicy**

Type	Field Name	Description
DDS_OctetSeq	value	default: empty

This policy is similar to the `GROUP_DATA` ([46.4 GROUP\\_DATA QosPolicy on page 748](#)) and `USER_DATA` ([47.30 USER\\_DATA QosPolicy on page 864](#)) policies that apply to other types of *Entities*.

### 45.1.1 Example

One possible use of `TOPIC_DATA` is to send an associated XML schema that can be used to process the data stored in the associated user data structure of the *Topic*. The schema, which can be passed as a long sequence of characters, could be used by an XML parser to take DDS samples of the data received for a *Topic* and convert them for updating some graphical user interface, web application or database.

### 45.1.2 Properties

This QosPolicy can be modified at any time. A change in the QosPolicy will cause *Connex* to send packets containing the new `TOPIC_DATA` to all of the other applications in the DDS domain.

Because *Topics* are created independently by the applications that use the *Topic*, there may be different instances of the same *Topic* (same topic name and DDS data type) in different applications. The `TOPIC_DATA` for different instances of the same *Topic* may be set differently by different applications.

### 45.1.3 Related QosPolicies

- [46.4 GROUP\\_DATA QosPolicy on page 748](#)
- [47.30 USER\\_DATA QosPolicy on page 864](#)
- [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 714](#)

### 45.1.4 Applicable DDS Entities

- [18.1 Topics on page 246](#)

## 45.1.5 System Resource Considerations

As mentioned earlier, the maximum size of the `TOPIC_DATA` is set in the **`topic_data_max_length`** field of the [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 714](#). Because *Connex* will allocate memory based on this value, you should only increase this value if you need to. If your system does not use `TOPIC_DATA`, then you can set this value to 0 to save memory. Setting the value of the `TOPIC_DATA` QosPolicy to hold data longer than the value set in the **`topic_data_max_length`** field will result in failure and an `INCONSISTENT_QOS_POLICY` return code.

However, should you decide to change the maximum size of `TOPIC_DATA`, you *must* make certain that all applications in the DDS domain have changed the value of **`topic_data_max_length`** to be the same. If two applications have different limits on the size of `TOPIC_DATA`, and one application sets the `TOPIC_DATA` QosPolicy to hold data that is greater than the maximum size set by another application, then the *DataWriters* and *DataReaders* of that *Topic* between the two applications will *not* connect. This is also true for the `GROUP_DATA` ([46.4 GROUP\\_DATA QosPolicy on page 748](#)) and `USER_DATA` ([47.30 USER\\_DATA QosPolicy on page 864](#)) QosPolicies.

# Chapter 46 Publisher/Subscriber QosPolicies

This section provides detailed information on the QosPolicies associated with a *Publisher* or *Subscriber*. *Publishers* and *Subscribers* have the same set of policies, except for [46.1 ASYNCHRONOUS\\_PUBLISHER QosPolicy \(DDS Extension\)](#) below, which is used only by *Publishers*. [Table 30.2 Publisher QosPolicies](#) provides a quick reference. They are presented here in alphabetical order.

- [46.1 ASYNCHRONOUS\\_PUBLISHER QosPolicy \(DDS Extension\)](#) below
- [46.2 ENTITYFACTORY QosPolicy](#) on page 743
- [46.3 EXCLUSIVE\\_AREA QosPolicy \(DDS Extension\)](#) on page 746
- [46.4 GROUP\\_DATA QosPolicy](#) on page 748
- [46.5 PARTITION QosPolicy](#) on page 751
- [46.6 PRESENTATION QosPolicy](#) on page 760

## 46.1 ASYNCHRONOUS\_PUBLISHER QosPolicy (DDS Extension)

This QosPolicy is used to enable or disable asynchronous publishing, asynchronous batch flushing, and TopicQuery publishing for the *Publisher*.

For each of these features enabled, the *Publisher* will spawn a thread. There is a thread for asynchronous publishing, a thread for asynchronous batch flushing, and a thread for TopicQuery publication.

The asynchronous publisher thread will be shared by all *DataWriters* (belonging to this *Publisher*) that have their [47.20 PUBLISH\\_MODE QosPolicy \(DDS Extension\)](#) on page 843 **kind** set to ASYNCHRONOUS. The asynchronous publishing thread will then handle the data trans-

mission chores for those *DataWriters*. This thread will only be spawned when the first of these *DataWriters* is enabled.

The asynchronous publisher thread can be used to reduce the amount of time spent in the user thread to send data. You must use it when sending large data reliably. Large in this context means that the data size is larger than the transport's **message\_size\_max**. See also [34.3 Large Data Fragmentation on page 524](#).

The asynchronous batch flushing thread will be shared by all *DataWriters* (belonging to this *Publisher*) that have batching enabled and **max\_flush\_delay** different than DURATION\_INFINITE in [47.2 BATCH QosPolicy \(DDS Extension\) on page 773](#). This thread will only be spawned when the first of these *DataWriters* is enabled.

The TopicQuery publication thread will be shared by all *DataWriters* (belonging to this *Publisher*) that have topic query dispatch enabled in [47.24 TOPIC\\_QUERY\\_DISPATCH QosPolicy \(DDS Extension\) on page 854](#). This thread will only be spawned when the first of these *DataWriters* is enabled.

This QosPolicy allows you to adjust the asynchronous publishing, the asynchronous batch flushing threads, and the TopicQuery publication threads independently.

Batching and asynchronous publication are independent of one another. Flushing a batch on an asynchronous *DataWriter* makes it available for sending to the *DataWriter's* [34.4 FlowControllers \(DDS Extension\) on page 532](#). From the point of view of the FlowController, a batch is treated like one large DDS sample.

*Connex* will sometimes coalesce multiple DDS samples into a single network datagram. For example, DDS samples buffered by a FlowController or sent in response to a negative acknowledgement (NACK) may be coalesced. This behavior is distinct from DDS sample batching. DDS data samples sent by different asynchronous *DataWriters* belonging to the same *Publisher* to the same destination will not be coalesced into a single network packet. Instead, two separate network packets will be sent. Only DDS samples written by the *same DataWriter* and intended for the *same destination* will be coalesced.

This QosPolicy includes the members in [Table 46.1 DDS\\_AsynchronousPublisherQosPolicy](#).

**Table 46.1 DDS\_AsynchronousPublisherQosPolicy**

Type	Field Name	Description
DDS_Boolean	disable_asynchronous_write	Disables asynchronous publishing. To write asynchronously, this field must be FALSE (the default).
DDS_ThreadSettings_t	thread	Settings for the publishing thread. These settings are OS-dependent (see the <a href="#">RTI Connex Core Libraries Platform Notes</a> ).
DDS_Boolean	disable_asynchronous_batch	Disables asynchronous batch flushing. To flush asynchronously, this field must be FALSE (the default).

Table 46.1 DDS\_AsynchronousPublisherQosPolicy

Type	Field Name	Description
DDS_ThreadSettings_t	asynchronous_batch_thread	Settings for the asynchronous batch flushing thread. These settings are OS-dependent (see the <a href="#">RTI Connext Core Libraries Platform Notes</a> ).
DDS_Boolean	disable_topic_query_publication	Disables TopicQuery publication. To allow publishing TopicQueries responses, this field must be FALSE (the default).
DDS_ThreadSettings_t	topic_query_publication_thread	Settings for the TopicQuery publication thread. These settings are OS-dependent (see the <a href="#">RTI Connext Core Libraries Platform Notes</a> ).

### 46.1.1 Properties

This QosPolicy cannot be modified after the *Publisher* is created.

Since it is only for *Publishers*, there are no compatibility restrictions for how it is set on the publishing and subscribing sides.

### 46.1.2 Related PropertyQos Policies

- **dds.domain\_participant.asynchronous\_publisher\_thread\_destruction\_timeout:** Maximum time in seconds the *DomainParticipant* will wait for the destruction of an asynchronous publisher thread. If this timeout expires before the asynchronous publisher thread is destroyed, the *DomainParticipant* cannot safely release the thread's resources, and it will skip their release. Default: 10 (seconds). Valid values: 1-60 (seconds).

### 46.1.3 Related QosPolicies

- If **disable\_asynchronous\_write** is TRUE (not the default), then any *DataWriters* created from this *Publisher* must have their [47.20 PUBLISH\\_MODE QosPolicy \(DDS Extension\) on page 843](#) **kind** set to SYNCHRONOUS. (Otherwise **create\_datawriter()** will return INCONSISTENT\_QOS.)
- If **disable\_asynchronous\_batch** is TRUE (not the default), then any *DataWriters* created from this *Publisher* must have **max\_flush\_delay** in [47.2 BATCH QosPolicy \(DDS Extension\) on page 773](#) set to DURATION\_INFINITE. (Otherwise **create\_datawriter()** will return INCONSISTENT\_QOS.)
- *DataWriters* configured to use the [47.16 MULTI\\_CHANNEL QosPolicy \(DDS Extension\) on page 830](#) do not support asynchronous publishing; an error is returned if a multi-channel *DataWriter* is configured for asynchronous publishing.
- If **disable\_topic\_query\_publication** is TRUE (not the default), then any *DataWriters* created from this *Publisher* must have **enable** in [47.24 TOPIC\\_QUERY\\_DISPATCH QosPolicy \(DDS Extension\) on page 854](#) to TRUE. (Otherwise **create\_datawriter()** will return INCONSISTENT\_QOS.)

## 46.1.4 Applicable DDS Entities

[Chapter 30 Publishers on page 373](#)

## 46.1.5 System Resource Considerations

Three threads can potentially be created:

- For asynchronous publishing, system resource usage depends on the activity of the asynchronous thread controlled by the FlowController (see [34.4 FlowControllers \(DDS Extension\) on page 532](#)).
- For asynchronous batch flushing, system resource usage depends on the activity of the asynchronous thread controlled by `max_flush_delay` in [47.2 BATCH QosPolicy \(DDS Extension\) on page 773](#).
- For TopicQuery publication, system resource usage depends on the activity of the TopicQuery publication thread controlled by [47.24 TOPIC\\_QUERY\\_DISPATCH QosPolicy \(DDS Extension\) on page 854](#).

## 46.2 ENTITYFACTORY QosPolicy

This QosPolicy controls whether or not child *Entities* are created in the enabled state.

This QosPolicy applies to the *DomainParticipantFactory*, *DomainParticipants*, *Publishers*, and *Subscribers*, which act as ‘factories’ for the creation of subordinate *Entities*. A *DomainParticipantFactory* is used to create *DomainParticipants*. A *DomainParticipant* is used to create both *Publishers* and *Subscribers*. A *Publisher* is used to create *DataWriters*, similarly a *Subscriber* is used to create *DataReaders*.

*Entities* can be created either in an ‘enabled’ or ‘disabled’ state. An enabled entity can actively participate in communication. A disabled entity cannot be discovered or take part in communication until it is explicitly enabled. For example, *Connex*t will not send data if the `write()` operation is called on a disabled *DataWriter*, nor will *Connex*t deliver data to a disabled *DataReader*. You can only enable a disabled entity. Once an entity is enabled, you cannot disable it, see [15.2 Enabling DDS Entities on page 35](#) about the `enable()` method.

The ENTITYFACTORY contains only one member, as illustrated in [Table 46.2 DDS\\_EntityFactoryQosPolicy](#).

**Table 46.2 DDS\_EntityFactoryQosPolicy**

Type	Field Name	Description
DDS_Boolean	autoenable_created_entities	DDS_BOOLEAN_TRUE: enable <i>Entities</i> when they are created DDS_BOOLEAN_FALSE: do not enable <i>Entities</i> when they are created

The ENTITYFACTORY QosPolicy controls whether the *Entities* created from the factory are automatically enabled upon creation or are left disabled. For example, if a *Publisher* is configured to autoenable created *Entities*, then all *DataWriters* created from that *Publisher* will be automatically enabled.

Note: if an entity is disabled, then all of the child *Entities* it creates are also created in a disabled state, regardless of the setting of this QosPolicy. However, enabling a disabled entity will enable all of its children if this QosPolicy is set to autoenable child *Entities*.

Note: an entity can only be enabled; it cannot be disabled after its been enabled.

See [46.2.1 Example on the next page](#) for an example of how to set this policy.

There are various reasons why you may want to create *Entities* in the disabled state:

- To get around a “chicken and egg”-type issue. Where you need to have an entity in order to modify it, but you don’t want the entity to be used by *Connex*t until it has been modified.

For example, if you create a *DomainParticipant* in the enabled state, it will immediately start sending packets to other nodes trying to discover if other *Connex*t applications exist. However, you may want to configure the built-in topic reader listener before discovery occurs. To do this, you need to create a *DomainParticipant* in the disabled state because once enabled, discovery will occur. If you set up the built-in topic reader listener after the *DomainParticipant* is enabled, you may miss some discovery traffic.

- You may want to create *Entities* without having them automatically start to work. This especially pertains to *DataReaders*. If you create a *DataReader* in an enabled state and you are using *DataReaderListeners*, *Connex*t will immediately search for matching *DataWriters* and callback the listener as soon as data is published. This may not be what you want to happen if your application is still in the middle of initialization when data arrives.

So typically, you would create all *Entities* in a disabled state, and then when all parts of the application have been initialized, one would enable all *Entities* at the same time using the *enable()* operation on the *DomainParticipant*, see [15.2 Enabling DDS Entities on page 35](#).

- An entity’s existence is not advertised to other participants in the network until the entity is enabled. Instead of sending an individual declaration packet to other applications announcing the existence of the entity, *Connex*t can be more efficient in bundling multiple declarations into a single packet when you enable all *Entities* at the same time.

See [15.2 Enabling DDS Entities on page 35](#) for more information about enabled/disabled *Entities*.

## 46.2.1 Example

The code in [Figure 46.1: Configuring a Publisher so that New DataWriters are Disabled](#) below illustrates how to use the ENTITYFACTORY QoS.

### Note:

- In C, you must initialize the QoS structures before they are used, see [42.2 Special QoS Policy Handling Considerations for C](#) on page 688.

**Figure 46.1: Configuring a Publisher so that New DataWriters are Disabled**

```
DDS_PublisherQos publisher_qos;
// topic, publisher, writer_listener already created
if (publisher->get_qos(publisher_qos) != DDS_RETCODE_OK) {
    // handle error
}
publisher_qos.entity_factory.autoenable_created_entities
    = DDS_BOOLEAN_FALSE;
if (publisher->set_qos(publisher_qos) != DDS_RETCODE_OK) {
    // handle error
}
// Subsequently created DataWriters are created disabled and
// must be explicitly enabled by the user-code
DDSDataWriter* writer = publisher->create_datawriter(topic,
    DDS_DATAWRITER_QOS_DEFAULT, writer_listener, DDS_STATUS_MASK_ALL);
// now do other initialization
// Now explicitly enable the DataWriter, this will allow other
// applications to discover the DataWriter and for this application
// to send data when the DataWriter's write() method is called
writer->enable();
```

## 46.2.2 Properties

This QoS Policy can be modified at any time.

It can be set differently on the publishing and subscribing sides.

## 46.2.3 Related QoS Policies

This QoS Policy does not interact with any other policies.

## 46.2.4 Applicable DDS Entities

- [16.2 DomainParticipantFactory](#) on page 75
- [16.3 DomainParticipants](#) on page 81
- [Chapter 30 Publishers](#) on page 373
- [Chapter 39 Subscribers](#) on page 597

## 46.2.5 System Resource Considerations

This QoSPolicy does not significantly impact the use of system resources.

## 46.3 EXCLUSIVE\_AREA QoSPolicy (DDS Extension)

This QoSPolicy is deprecated as of release 6.1.1 and will be removed in a future release.

This QoSPolicy controls the creation and use of Exclusive Areas. An exclusive area (EA) is a mutex with built-in deadlock protection when multiple EAs are in use. It is used to provide mutual exclusion among different threads of execution. Multiple EAs allow greater concurrency among the internal and user threads when executing *Connex*t code.

EAs allow *Connex*t to be multi-threaded while preventing threads from a classical deadlock scenario for multi-threaded applications. EAs prevent a *DomainParticipant's* internal threads from deadlocking with each other when executing internal code as well as when executing the code of user-registered listener callbacks.

Within an EA, all calls to the code protected by the EA are single threaded. Each *DomainParticipant*, *Publisher* and *Subscriber* represents a separate EA. All *DataWriters* of the same *Publisher* and all *DataReaders* of the same *Subscriber* share the EA of its parent. This means that the *DataWriters* of the same *Publisher* and the *DataReaders* of the same *Subscriber* are inherently single threaded.

Within an EA, there are limitations on how code protected by a different EA can be accessed. For example, when data is being processed by user code received in the *DataReaderListener* of a *Subscriber* EA, the user code may call the *write()* function of a *DataWriter* that is protected by the EA of its *Publisher*. So you can send data in the function called to process received data. However, you cannot create *Entities* or call functions that are protected by the EA of the *DomainParticipant*. See [15.8.8 Exclusive Areas \(EAs\) on page 54](#) for the complete documentation on Exclusive Areas.

With this QoS, you can force a *Publisher* or *Subscriber* to share the same EA as its *DomainParticipant*. Using this capability, the restriction of not being to create *Entities* in a *DataReaderListener's* **on\_data\_available()** callback is lifted. However, the trade-off is that the application has reduced concurrency through the *Entities* that share an EA.

Note that the restrictions on calling methods in a different EA only exists for user code that is called in registered Listeners by internal *DomainParticipant* threads. User code may call all *Connex*t functions for any *Entities* from their own threads at any time.

The EXCLUSIVE\_AREA includes a single member, as listed in [Table 46.3 DDS\\_ExclusiveAreaQoSPolicy](#). For the default value, please see the API Reference HTML documentation.

Table 46.3 DDS\_ExclusiveAreaQosPolicy

Type	Field Name	Description
DDS_Boolean	use_shared_exclusive_area	DDS_BOOLEAN_FALSE: subordinates will not use the same EA  DDS_BOOLEAN_TRUE: subordinates will use the same EA

The implications and restrictions of using a private or shared EA are discussed in [15.8.8 Exclusive Areas \(EAs\) on page 54](#). The basic trade-off is concurrency versus restrictions on which methods can be called in user, listener, callback functions. To summarize:

**Behavior when the *Publisher* or *Subscriber*'s use\_shared\_exclusive\_area is set to *FALSE*:**

- The creation of the *Publisher/Subscriber* will create an EA that will be used only by the *Publisher/Subscriber* and the *DataWriters/DataReaders* that belong to them.
- Consequences: This setting maximizes concurrency at the expense of creating a mutex for the *Publisher* or *Subscriber*. In addition, using a separate EA may restrict certain *Connex*t operations (see [15.8.6 Operations Allowed within Listener Callbacks on page 53](#)) from being called from the callbacks of Listeners attached to those *Entities* and the *Entities* that they create. This limitation results from a built-in deadlock protection mechanism.

**Behavior when the *Publisher* or *Subscriber*'s use\_shared\_exclusive\_area is set to *TRUE*:**

- The creation of the *Publisher/Subscriber* does not create a new EA. Instead, the *Publisher/Subscriber*, along with the *DataWriters/DataReaders* that they create, will use a common EA shared with the *DomainParticipant*.
- Consequences: By sharing the same EA among multiple *Entities*, you may decrease the amount of concurrency in the application, which can adversely impact performance. However, this setting does use less resources and allows you to call almost any operation on any Entity within a listener callback (see [15.8.8 Exclusive Areas \(EAs\) on page 54](#) for full details).

### 46.3.1 Example

The code in [Figure 46.2: Creating a Publisher with a Shared Exclusive Area on the next page](#) illustrates how to change the EXCLUSIVE\_AREA policy.

**Note:**

- In C, you must initialize the QoS structures before they are used, see [42.2 Special QoSPolicy Handling Considerations for C on page 688](#).

Figure 46.2: Creating a Publisher with a Shared Exclusive Area

```

DDS_PublisherQos publisher_qos;
// domain, publisher_listener have been previously created
if (participant->get_default_publisher_qos(publisher_qos) !=
    DDS_RETCODE_OK) {
    // handle error
}
publisher_qos.exclusive_area.use_shared_exclusive_area = DDS_BOOLEAN_TRUE;
DDS_Publisher* publisher = participant->create_publisher(publisher_qos,
    publisher_listener, DDS_STATUS_MASK_ALL);

```

## 46.3.2 Properties

This QosPolicy cannot be modified after the Entity has been created.

It can be set differently on the publishing and subscribing sides.

## 46.3.3 Related QosPolicies

This QosPolicy does not interact with any other policies.

## 46.3.4 Applicable DDS Entities

- [Chapter 30 Publishers on page 373](#)
- [Chapter 39 Subscribers on page 597](#)

## 46.3.5 System Resource Considerations

This QosPolicy affects the use of operating-system mutexes. When `use_shared_exclusive_area` is `FALSE`, the creation of a *Publisher* or *Subscriber* will create an operating-system mutex.

## 46.4 GROUP\_DATA QosPolicy

This QosPolicy provides an area where your application can store additional information related to the *Publisher* and *Subscriber*. This information is passed between applications during discovery (see [Discovery Overview \(Chapter 22 on page 309\)](#)) using built-in-topics (see [Accessing Discovery Information through Built-In Topics \(Chapter 28 on page 359\)](#)). How this information is used will be up to user code. *Connex* does not do anything with the information stored as `GROUP_DATA` except to pass it to other applications.

Use cases are often application-to-application identification, authentication, authorization, and encryption purposes. For example, applications can use this QosPolicy to send security certificates to each other for RSA-type security.

The value of the `GROUP_DATA` QosPolicy is sent to remote applications when they are first discovered, as well as when the *Publisher* or *Subscriber*'s `set_qos()` method is called after changing the

value of the `GROUP_DATA`. User code can set listeners on the built-in *DataReaders* of the built-in *Topics* used by *Connex* to propagate discovery information. Methods in the built-in topic listeners will be called whenever new *DomainParticipants*, *DataReaders*, and *DataWriters* are found. Within the user callback, you will have access to the `GROUP_DATA` that was set for the associated *Publisher* or *Subscriber*.

Currently, `GROUP_DATA` of the associated *Publisher* or *Subscriber* is only propagated with the information that declares a *DataWriter* or *DataReader*. Thus, you will need to access the value of `GROUP_DATA` through `DDS_PublicationBuiltinTopicData` or `DDS_SubscriptionBuiltinTopicData` (see [Accessing Discovery Information through Built-In Topics \(Chapter 28 on page 359\)](#)).

The structure for the `GROUP_DATA` `QoS`Policy includes just one field, as seen in [Table 46.4 DDS\\_GroupDataQoS](#)Policy. The field is a sequence of octets that translates to a contiguous buffer of bytes whose contents and length is set by the user. The maximum size for the data are set in the [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QoS](#)Policy (DDS Extension) on page 714.

**Table 46.4 DDS\_GroupDataQoS**Policy

Type	Field Name	Description
DDS_OctetSeq	value	Empty by default

This policy is similar to the [47.30 USER\\_DATA QoS](#)Policy on page 864 and [45.1 TOPIC\\_DATA QoS](#)Policy on page 737 that apply to other types of *Entities*.

## 46.4.1 Example

One possible use of `GROUP_DATA` is to pass some credential or certificate that your subscriber application can use to accept or reject communication with the *DataWriters* that belong to the *Publisher* (or vice versa, where the publisher application can validate the permission of *DataReaders* of a *Subscriber* to receive its data). The value of the `GROUP_DATA` of the *Publisher* is propagated in the ‘group\_data’ field of the `DDS_PublicationBuiltinTopicData` that is sent with the declaration of each *DataWriter*. Similarly, the value of the `GROUP_DATA` of the *Subscriber* is propagated in the ‘group\_data’ field of the `DDS_SubscriptionBuiltinTopicData` that is sent with the declaration of each *DataReader*.

When *Connex* discovers a *DataWriter/DataReader*, the application can be notified of the discovery of the new entity and retrieve information about the *DataWriter/DataReader* `QoS` by reading the `DCPS`Publication or `DCPS`Subscription built-in topics (see [Accessing Discovery Information through Built-In Topics \(Chapter 28 on page 359\)](#)). Your application can then examine the `GROUP_DATA` field in the built-in Topic and decide whether or not the *DataWriter/DataReader* should be allowed to communicate with local *DataReaders/DataWriters*. If communication is not allowed, the application can use the *DomainParticipant*’s `ignore_publication()` or `ignore_subscription()` operation to reject the newly discovered remote entity as one with which the application allows *Connex* to communicate. See [Figure 27.2: Ignoring Publications on page 355](#) for an example of how to do this.

The code in [Figure 46.3: Creating a Publisher with GROUP\\_DATA below](#) illustrates how to change the GROUP\_DATA policy.

**Note:**

- In C, you must initialize the QoS structures before they are used, see [42.2 Special QoS Policy Handling Considerations for C](#) on page 688.

**Figure 46.3: Creating a Publisher with GROUP\_DATA**

```
DDS_PublisherQos publisher_qos;
int i = 0;
// Bytes that will be used for the group data. In this case, 8 bytes
// of some information that is meaningful to the user application
char myGroupData[GROUP_DATA_SIZE] =
    { 0x34, 0xaa, 0xfe, 0x31, 0x7a, 0xf2, 0x34, 0xaa};
// assume domainparticipant and publisher_listener already created
if (participant->get_default_publisher_qos(publisher_qos) !=
    DDS_RETCODE_OK) {
    // handle error
}
// Must set the size of the sequence first
publisher_qos.group_data.value.maximum(GROUP_DATA_SIZE);
publisher_qos.group_data.value.length(GROUP_DATA_SIZE);
for (i = 0; i < GROUP_DATA_SIZE; i++) {
    publisher_qos.group_data.value[i] = myGroupData[i]
}
DDSPublisher* publisher = participant->create_publisher( publisher_qos,
    publisher_listener, DDS_STATUS_MASK_ALL);
```

## 46.4.2 Properties

This QoSPolicy can be modified at any time.

It can be set differently on the publishing and subscribing sides.

## 46.4.3 Related QoS Policies

- [45.1 TOPIC\\_DATA QoS Policy](#) on page 737
- [47.30 USER\\_DATA QoS Policy](#) on page 864
- [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QoS Policy \(DDS Extension\)](#) on page 714

## 46.4.4 Applicable DDS Entities

- [Chapter 30 Publishers](#) on page 373
- [Chapter 39 Subscribers](#) on page 597

## 46.4.5 System Resource Considerations

The maximum size of the `GROUP_DATA` is set in the `publisher_group_data_max_length` and `subscriber_group_data_max_length` fields of the [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QoSPolicy \(DDS Extension\) on page 714](#). Because *Connex* will allocate memory based on this value, you should only increase this value if you need to. If your system does not use `GROUP_DATA`, then you can set this value to zero to save memory. Setting the value of the `GROUP_DATA` QoSPolicy to hold data longer than the value set in the `[publisher/subscriber]_group_data_max_length` fields will result in failure and an `INCONSISTENT_QOS_POLICY` return code.

However, should you decide to change the maximum size of `GROUP_DATA`, you *must* make certain that all applications in the DDS domain have changed the value of `[publisher/subscriber]_group_data_max_length` to be the same. If two applications have different limits on the size of `GROUP_DATA`, and one application sets the `GROUP_DATA` QoSPolicy to hold data that is greater than the maximum size set by another application, then the matching *DataWriters* and *DataReaders* of the *Publisher* and *Subscriber* between the two applications will *not* connect. This is also true for the `TOPIC_DATA` ([45.1 TOPIC\\_DATA QoSPolicy on page 737](#)) and `USER_DATA` ([47.30 USER\\_DATA QoSPolicy on page 864](#)) QoS Policies.

## 46.5 PARTITION QoSPolicy

The `PARTITION` QoS provides another way to control which *Entities* will match—and thus communicate with—which other *Entities*. It can be used to prevent *Entities* that would have otherwise matched from talking to each other. Much in the same way that only applications within the same DDS domain will communicate with each other, only *Entities* that belong to the same partition can talk to each other.

See also [16.3.5 Isolating DomainParticipants and Endpoints from Each Other on page 91](#) for an overview of your options for isolating or partitioning data.

The `PARTITION` QoS applies to *Publishers*, *Subscribers*, and *DomainParticipants*. *DataWriters* and *DataReaders* belong to the partitions as set in the QoS of the *Publishers* and *Subscribers* that created them. *DomainParticipants* belong to the partitions as set in the *DomainParticipants'* QoS.

The mechanism implementing the `PARTITION` QoS is relatively lightweight compared to the creation and deletion of *Entities*, and membership in a partition can be dynamically changed.

The `PARTITION` QoS consists of a set of partition names that identify the partitions of which the *Entity* is a member. These names can be concrete (e.g., `ExamplePartition`) or regular expression strings (e.g., `Example*`), and two *Entities* are considered to be in the same partition if one of the *Entities* has a concrete partition name matching one of the concrete or regular expression partition names of the other *Entity* (see [46.5.2 Pattern Matching for PARTITION Names on page 754](#)). By default, *DomainParticipants*, and *DataWriters* and *DataReaders* (through their *Publisher/Subscriber* parents), belong to a single partition whose name is the empty string, `""`.

Conceptually, each partition name can be thought of as defining a “visibility plane” within the DDS domain:

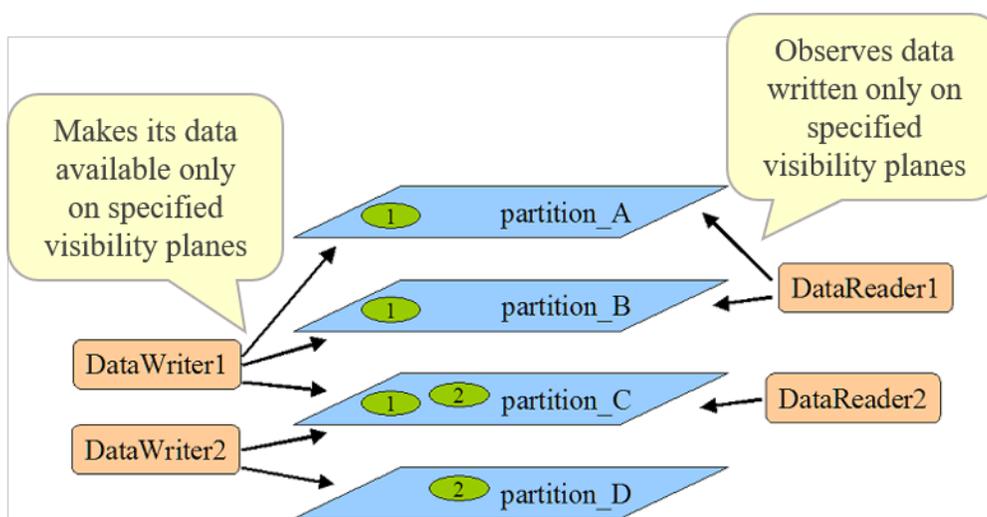

- *DataWriters* will make their data available on all of the visibility planes that correspond to their *Publisher’s* partition names, and the *DataReaders* will see the data that is placed on all of the visibility planes that correspond to their *Subscriber’s* partition names.
- *DomainParticipants* with the same domain ID (see [16.3.4 Choosing a Domain ID and Creating Multiple DDS Domains on page 90](#)) and domain tag (see [16.3.5.1 Choosing a Domain Tag on page 92](#)) will be visible to each other if they share a common visibility plane defined by the *DomainParticipants’* partition names.

Partitioning at the *DomainParticipant* level can be particularly useful in large, WAN, distributed systems (with thousands of participants) in which not all participants need to know about each other at any given time. Partitioning at the *DomainParticipant* level helps reduce network, CPU, and memory utilization, because *DomainParticipants* without matching partitions will not exchange information about their *DataWriters* and *DataReaders*.

*DomainParticipant* partitions and *Publisher/Subscriber* partitions are independent of each other. You can use both features independently or in combination to provide the right level of isolation.

[Figure 46.4: Controlling Visibility of Data with the PARTITION QoS below](#) illustrates the concept of PARTITION QoS at the *Publisher* and *Subscriber* level. In this figure, all *DataWriters* and *DataReaders* belong to the same DDS domain ID, domain tag, and *DomainParticipant* partition, and they use the same *Topic*. *DataWriter1* is configured to belong to three partitions: `partition_A`, `partition_B`, and `partition_C`. *DataWriter2* belongs to `partition_C` and `partition_D`.

**Figure 46.4: Controlling Visibility of Data with the PARTITION QoS**

Similarly, *DataReader1* is configured to belong to `partition_A` and `partition_B`, and *DataReader2* belongs only to `partition_C`. Given this topology, the data written by *DataWriter1* is visible in

partitions A, B, and C. The oval tagged with the number “1” represents one DDS data sample written by *DataWriter1*.

Similarly, the data written by *DataWriter2* is visible in partitions C and D. The oval tagged with the number “2” represents one DDS data sample written by *DataWriter2*.

The result is that the data written by *DataWriter1* will be received by both *DataReader1* and *DataReader2*, but the data written by *DataWriter2* will only be visible by *DataReader2*.

*Publishers* and *Subscribers* always belong to a partition. By default, *Publishers* and *Subscribers* belong to a single partition whose name is the empty string, "". If you set the PARTITION QoS to be an empty set, *Connex* will assign the *Publisher* or *Subscriber* to the default partition, "". Thus, for the example above, without using the PARTITION QoS on any of the entities, *DataReaders* 1 and 2 would have received all data samples written by *DataWriters* 1 and 2.

## 46.5.1 Rules for PARTITION Matching

The PARTITION QoSPolicy associates a set of partition names with the entity (*DomainParticipant*, *Publisher*, or *Subscriber*). The partition names are concrete names (e.g., ExamplePartition) or regular expression strings (e.g., Example\*).

With regard to the PARTITION QoS, a *DataWriter* will communicate with a *DataReader* if and only if the following conditions apply:

1. The *DataWriter* and *DataReader* belong to *DomainParticipants* bound to the same DDS domain ID, domain tag, and at least one matching *DomainParticipant* partition (see [16.3.1 Creating a DomainParticipant on page 87](#), [16.3.4 Choosing a Domain ID and Creating Multiple DDS Domains on page 90](#), and [16.3.5.1 Choosing a Domain Tag on page 92](#)).
2. The *DataWriter* and *DataReader* have matching *Topics*. That is, each is associated with a *Topic* with the same name and compatible data type.
3. The QoS offered by the *DataWriter* is compatible with the QoS requested by the *DataReader*.
4. The application has not used the **ignore\_participant()**, **ignore\_datareader()**, or **ignore\_datawriter()** APIs to prevent the association (see [Chapter 27 Restricting Communication—Ignoring Entities on page 352](#)).
5. The *Publisher* to which the *DataWriter* belongs and the *Subscriber* to which the *DataReader* belongs must have at least one matching partition name.

Matching partition names is done by string pattern matching, and partition names are case-sensitive.

**Note:** Failure to match partitions (on *Publisher*, *Subscriber*, or *DomainParticipant*) is not considered an incompatible QoS and does not trigger any listeners or change any status conditions.

## 46.5.2 Pattern Matching for PARTITION Names

You may also add strings that are regular expressions (as defined in the POSIX fnmatch API (1003.2-1992 Section B.6)) to the PARTITION QoSPolicy. A regular expression does not define a set of partitions to which the *Entity* (*Publisher*, *Subscriber*, or *DomainParticipant*) belongs, as much as it is used in the partition matching process to see if a remote entity has a partition name that would be matched with the regular expression. That is, the regular expressions in the PARTITION QoS of an *Entity* are never matched against the regular expressions found in the PARTITION QoS of a different *Entity*. Regular expressions are always matched against “concrete” partition names. Thus, a concrete partition name may not contain any reserved characters that are used to define regular expressions, for example ‘\*’, ‘.’, ‘+’, etc.

For more on regular expressions, see [35.5.5 SQL Extension: Regular Expression Matching on page 560](#).

If a PARTITION QoS only contains regular expressions, then the *Entity* will be assigned automatically to the default partition with the empty string name (“”). Thus, a PARTITION QoS that only contains the string “\*” matches another *Entity*'s PARTITION QoS that also only contains the string “\*”, not because the regular expression strings are identical, but because they both belong to the default "" partition.

Two *Entities* are considered to have a partition in common if the sets of partitions associated with them have:

- At least one concrete partition name in common
- A regular expression in one *Entity* that matches a concrete partition name in another *Entity*

The programmatic representation of the PARTITION QoS is shown in [Table 46.5 DDS\\_PartitionQoSPolicy](#). The QoSPolicy contains the single string sequence, name. Each element in the sequence can be a concrete name or a regular expression. The *Entity* will be assigned to the default "" partition if the sequence is empty, or if the sequence contains only regular expressions.

**Table 46.5 DDS\_PartitionQoSPolicy**

Type	Field Name	Description
DDS_StringSeq	name	Empty by default. There can be up to 64 names, with a maximum of 256 characters summed across all names.

You can have one long partition string of 256 chars, or multiple shorter strings that add up to 256 or fewer characters. For example, you can have one string of 4 chars and one string of 252 chars.

## 46.5.3 Example

Since the set of partitions for a *Publisher* or *Subscriber* can be dynamically changed, the PARTITION QoS Policy is useful to control which *DataWriters* can communicate with which *DataReaders* and vice versa—even if all of the *DataWriters* and *DataReaders* are for the same *Topic*. This facility is useful for creating temporary separation groups among *Entities* that would otherwise be connected to and exchange data each other.

Note when using Partitions and Durability: If a *Publisher* changes partitions after startup, it is possible for a reliable, late-joining *DataReader* to receive data that was written for both the original and the new partition. For example, suppose a *DataWriter* with TRANSIENT\_LOCAL Durability initially writes DDS samples with Partition A, but later changes to Partition B. In this case, a reliable, late-joining *DataReader* configured for Partition B will receive whatever DDS samples have been saved for the *DataWriter*. These may include DDS samples which were written when the *DataWriter* was using Partition A.

The code in [Figure 46.5: Setting Partition Names on a Publisher below](#) illustrates how to change the PARTITION QoS Policy.

### Note:

- In C, you must initialize the QoS structures before they are used, see [42.2 Special QoS Policy Handling Considerations for C on page 688](#).

**Figure 46.5: Setting Partition Names on a Publisher**

```
DDS_PublisherQos publisher_qos;
// domain, publisher_listener have been previously created
if (participant->get_default_publisher_qos(publisher_qos) !=
    DDS_RETCODE_OK) {
    // handle error
}
// Set the partition QoS
publisher_qos.partition.name.maximum(3);
publisher_qos.partition.name.length(3);
publisher_qos.partition.name[0] = DDS_String_dup("partition_A");
publisher_qos.partition.name[1] = DDS_String_dup("partition_B");
publisher_qos.partition.name[2] = DDS_String_dup("partition_C");
DDSPublisher* publisher = participant->create_publisher(
    publisher_qos, publisher_listener, DDS_STATUS_MASK_ALL);
```

The ability to dynamically control which *DataWriters* are matched to which *DataReaders* (of the same *Topic*) offered by the PARTITION QoS can be used in many different ways. Using partitions, connectivity can be controlled based on location-based partitioning, access-control groups, purpose, or a combination of these and other application-defined criteria. We will examine some of these options via concrete examples.

*Example of location-based partitions.* Assume you have a set of *Topics* in a traffic management system such as “TrafficAlert,” “AccidentReport,” and “CongestionStatus.” You may want to control the visibility of these *Topics* based on the actual location to which the information applies. You can do this by placing the *Publisher* in a partition that represents the area to which the information applies. This can be done using a string that includes the city, state, and country, such as “USA/California/Santa Clara.” A *Subscriber* can then choose whether it wants to see the alerts in a single city, the accidents in a set of states, or the congestion status across the US. Some concrete examples are shown in [Table 46.6 Example of Using Location-Based Partitions](#).

**Table 46.6 Example of Using Location-Based Partitions**

Publisher Partitions	Subscriber Partitions	Result
Specify a single partition name using the pattern: “<country>/<state>/<city>”	Specify multiple partition names, one per region of interest	Limits the visibility of the data to Subscribers that express interest in the geographical region.
“USA/California/Santa Clara”	(Subscriber partition is irrelevant here.)	Send only information for Santa Clara, California.
(Publisher partition is irrelevant here.)	“USA/California/Santa Clara”	Receive only information for Santa Clara, California.
	“USA/California/Santa Clara” “USA/California/Sunnyvale”	Receive information for Santa Clara or Sunnyvale, California.
	“USA/California/*” “USA/Nevada/*”	Receive information for California or Nevada.
	“USA/California/*” “USA/Nevada/Reno” “USA/Nevada/Las Vegas”	Receive information for California and two cities in Nevada.

*Example of access-control group partitions.* Suppose you have an application where access to the information must be restricted based on reader membership to access-control groups. You can map this group-controlled visibility to partitions by naming all the groups (e.g. executives, payroll, financial, general-staff, consultants, external-people) and assigning the *Publisher* to the set of partitions that represents which groups should have access to the information. The *Subscribers* specify the groups to which they belong, and the partition-matching behavior will ensure that the information is only distributed to *Subscribers* belonging to the appropriate groups. Some concrete examples are shown in [Table 46.7 Example of Access-Control Group Partitions](#).

**Table 46.7 Example of Access-Control Group Partitions**

Publisher Partitions	Subscriber Partitions	Result
Specify several partition names, one per group that is allowed access:	Specify multiple partition names, one per group to which the Subscriber belongs.	Limits the visibility of the data to Subscribers that belong to the access-groups specified by the Publisher.
"payroll" "financial"	(Subscriber partition is irrelevant here.)	Makes information available only to Subscribers that have access to either financial or payroll information.
(Publisher partition is irrelevant here.)	"executives" "financial"	Gain access to information that is intended for executives or people with access to the finances.

A slight variation of this pattern could be used to confine the information based on security levels.

*Example of purpose-based partitions:* Assume an application containing subsystems that can be used for multiple purposes, such as training, simulation, and real use. In some occasions it is convenient to be able to dynamically switch the subsystem from operating in the “simulation world” to the “training world” or to the “real world.” For supervision purposes, it may be convenient to observe multiple worlds, so that you can compare the each one’s results. This can be accomplished by setting a partition name in the *Publisher* that represents the “world” to which it belongs and a set of partition names in the *Subscriber* that represents the worlds that it can observe.

## 46.5.4 Properties

This QosPolicy can be modified at any time.

Strictly speaking, this QosPolicy does not have request-offered semantics, although it is matched between *DataWriters* and *DataReaders*, and communication is established only if there is a match between partition names.

## 46.5.5 Related QosPolicies

- [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 714](#)

## 46.5.6 Applicable DDS Entities

- [16.3 DomainParticipants on page 81](#)
- [Chapter 30 Publishers on page 373](#)
- [Chapter 39 Subscribers on page 597](#)

## 46.5.7 System Resource Considerations

Partition names are propagated with the discovery traffic and can be examined by user code through built-in topics (see [Accessing Discovery Information through Built-In Topics \(Chapter 28 on](#)

page 359)). *DomainParticipant* partitions are propagated with participant discovery traffic, and *Publisher* and *Subscriber* partitions are propagated with endpoint discovery traffic.

The maximum number of partitions and the maximum number of characters that can be used for the sum-total length of all partition names are configured using the `max_partitions` and `max_partition_cumulative_characters` fields of the [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 714](#). Setting more partitions or using longer names than allowed by those limits will result in failure and an `INCONSISTENT_QOS_POLICY` return code.

However, should you decide to change the maximum number of partitions or maximum cumulative length of partition names, then you *must* make certain that all applications in the DDS domain have changed the values of `max_partitions` and `max_partition_cumulative_characters` to be the same. If two applications have different values for those settings, and one application sets the `PARTITION` QosPolicy to hold more partitions or longer names than set by another application, then the matching *Entities* between the two applications will *not* connect. This is similar to the restrictions for the `GROUP_DATA` ([46.4 GROUP\\_DATA QosPolicy on page 748](#)), `USER_DATA` ([47.30 USER\\_DATA QosPolicy on page 864](#)), and `TOPIC_DATA` ([45.1 TOPIC\\_DATA QosPolicy on page 737](#)) QosPolicies.

## 46.5.8 Partition Changes

### 46.5.8.1 DomainParticipant Partitions Changes

When a *DomainParticipant*'s partitions change, the *DomainParticipant* sends a new participant announcement to all the matching *DomainParticipants* and all the initial peers. The message is sent over the participant announcement channel, which is best-effort.

#### 46.5.8.1.1 Changing from Match to Unmatch

When a local *DomainParticipant* unmatches with a remote *DomainParticipant*, it goes through the same process it would go through if the remote participant were deleted or otherwise lost liveliness. All information for the remote *DomainParticipant* is purged, including the matches with the remote participant's *DataWriters* and *DataReaders*.

Before unmatching with the remote *DomainParticipant*, the local *DomainParticipants* sends a participant announcement notification. After that, the local *DomainParticipant* no longer sends the announcements, unless the remote participant's discovery locator(s) are a part of the local participant's **initial\_peers** list. Therefore, if the local participant announcement containing the partition change is lost and the remote *DomainParticipant* discovery locator is not part of the local *DomainParticipants*'s initial peers, the local *DomainParticipant* will end up losing liveliness with the remote *DomainParticipant*.

The unmatch operation can be detected in the local *DomainParticipant* by monitoring the `DCPSParticipant` built-in *Topic* (see [Chapter 28 Accessing Discovery Information through Built-In Topics on page 359](#)). The application will receive a sample with **instance\_state** set to `NOT_ALIVE_NO_WRITERS` for each unmatched remote *DomainParticipant*.

There will also be changes to the [31.6.7 PUBLICATION\\_MATCHED Status on page 405](#) or [40.7.9 SUBSCRIPTION\\_MATCHED Status on page 642](#) in the local *DomainParticipant's DataReaders* and *DataWriters* that previously matched with the remote participant's *DataReaders* and *DataWriters*.

#### 46.5.8.1.2 Changing from Unmatch to Match

The local *DomainParticipant* changing partitions will match with a remote *DomainParticipant* when it receives a new participant announcement from the remote *DomainParticipant*. Unlike with *Publisher* and *Subscriber* partitions, this change may take some time. In the worst-case scenario, the change depends on how fast the *DomainParticipants* send participant announcements.

#### 46.5.8.2 Publisher/Subscriber Partitions Changes

When the partitions of a *Publisher* or *Subscriber* change, the *DomainParticipant* will send new publication or subscription announcements (*publication DATAs* and *subscription DATAs*) to all matching *DomainParticipants*. These messages are sent over the DCPSPublication and DCPSSubscription reliable channels (see [Chapter 28 Accessing Discovery Information through Built-In Topics on page 359](#) and [22.3 Simple Endpoint Discovery on page 317](#)).

For a *Publisher*, the *DomainParticipant* will send one *publication DATAs* announcement per (*Publisher's DataWriter*, remote *DomainParticipant* locator) pair. For a *Subscriber*, the *DomainParticipant* will send one *subscription DATAs* announcement per (*Subscriber's DataReader*, remote *DomainParticipant* locator) pair.

##### 46.5.8.2.1 Changing from Match to Unmatch

The local *Entity* (*DataWriter* or *DataReader*) that is changing partitions immediately unmatches the previously matching *Entities*. The remote *Entity* will unmatch the local *Entity* changing partitions as soon as it receives the endpoint (*publication DATAs* and *subscription DATAs*) announcement from the local *Entity*. For the local and remote *Entity*, the unmatch operation can be detected by monitoring the [31.6.7 PUBLICATION\\_MATCHED Status on page 405](#) or [40.7.9 SUBSCRIPTION\\_MATCHED Status on page 642](#).

When a *DataWriter* unmatches a *DataReader* because of a change in partitions, the *DataWriter* will stop sending samples immediately to the *DataReader*.

When a *DataReader* unmatches a *DataWriter* because of a change in partitions, the *DataReader's DomainParticipant* will drop samples coming from the *DataWriter*, so that the *DataReader* never receives them. If a reliable *DataWriter* has not yet detected the change, it may end up filling its send window and blocking new write operations until the *DataReader* is deactivated due to lack of responsiveness to HB messages (see [32.4.4.4 Controlling How Many Times Heartbeats are Resent \(max\\_heartbeat\\_retries\) on page 467](#)).

### 46.5.8.3 Changing from Unmatch to Match

The local *Entity* (*DataWriter* or *DataReader*) that is changing partitions immediately matches other *Entities* that previously did not match. The remote *Entity* will match the *Entity* changing partitions as soon as it receives the endpoint (*publication DATAs* and *subscription DATAs*) announcement. The match operation can be detected by the local and remote *Entity* by monitoring the [31.6.7 PUBLICATION\\_MATCHED Status on page 405](#) or [40.7.9 SUBSCRIPTION\\_MATCHED Status on page 642](#).

Because the partition change has to be propagated, there will be a delay before the *DataReader* starts receiving samples from matched *DataWriters*.

## 46.6 PRESENTATION QosPolicy

Usually *DataReaders* will receive data in the order that it was sent by a *DataWriter*. In addition, data is presented to the *DataReader* as soon as the application receives the next value expected.

Sometimes, you may want a set of data for the same *DataWriter* or different *DataWriters* to be presented to the receiving *DataReader(s)* only after ALL the elements of the set have been received, but not before. You may also want the data to be presented in a different order than it was received. Specifically, for keyed data, you may want *Connnext* to present the data in keyed or instance order.

The Presentation QosPolicy allows you to specify different scopes of presentation: within a *DataWriter*, across instances of a *DataWriter*, and even across different *DataWriters* of a Publisher. It also controls whether or not a set of changes within the scope must be delivered at the same time or delivered as soon as each element is received. The structure used is shown in [Table 46.8 DDS\\_PresentationQosPolicy](#).

Table 46.8 DDS\_PresentationQosPolicy

Type	Field Name	Description
DDS_Presentation_QosPolicyAccessScopeKind	access_scope	<p>Determines the largest scope spanning the entities for which the <b>ordered_access</b> and <b>coherent_access</b> of samples can be preserved (if <b>coherent_access</b> and/or <b>ordered_access</b> are TRUE).</p> <p><b>access_scope</b>'s setting has no effect unless either <b>coherent_access</b> or <b>ordered_access</b> is set to TRUE.</p> <ul style="list-style-type: none"> <li>DDS_INSTANCE_PRESENTATION_QOS (default): Scope spans only a single instance. Changes to one instance need not be coherent nor ordered with respect to changes to any other instance. Order and coherent changes apply to each instance separately.</li> <li>DDS_TOPIC_PRESENTATION_QOS: Scope spans all instances within the same <i>DataWriter</i>, but not across instances in different <i>DataWriters</i>.</li> <li>DDS_GROUP_PRESENTATION_QOS: Scope spans all instances belonging to <i>DataWriters</i> within the same <i>Publisher</i>.</li> <li>DDS_HIGHEST_OFFERED_PRESENTATION_QOS: Only applies to <i>Subscribers</i>. With this setting, the <i>Subscriber</i> will use the access scope specified by each remote <i>Publisher</i>.</li> </ul>
DDS_Boolean	coherent_access	<p>Controls whether <i>Connex</i> will preserve the groupings of changes made by the publishing application by means of <b>begin_coherent_changes()</b> and <b>end_coherent_changes()</b>.</p> <ul style="list-style-type: none"> <li>DDS_BOOLEAN_FALSE (default): Coherency is not preserved. The value of <b>access_scope</b> is ignored.</li> <li>DDS_BOOLEAN_TRUE: Changes made to instances within each <i>DataWriter</i> will be available to the <i>DataReader</i> as a coherent set, based on the value of <b>access_scope</b>.</li> </ul>
DDS_Boolean	ordered_access	<p>Controls whether <i>Connex</i> will preserve the order of changes.</p> <ul style="list-style-type: none"> <li>DDS_BOOLEAN_FALSE (default): The order of DDS samples is only preserved for each instance, not across instances. The value of <b>access_scope</b> is ignored.</li> <li>DDS_BOOLEAN_TRUE: The order of DDS samples from a <i>DataWriter</i> is preserved, based on the value set in <b>access_scope</b>.</li> </ul>
DDS_Boolean	drop_incomplete_coherent_set	<p>Indicates whether a <i>DataReader</i> should drop (and report as lost) samples from an incomplete coherent set (one for which not all the samples were received):</p> <ul style="list-style-type: none"> <li>DDS_BOOLEAN_FALSE: The <i>DataReader</i> will not drop samples that are part of an incomplete coherent set.</li> <li>DDS_BOOLEAN_TRUE (default): The <i>DataReader</i> will drop samples that are part of an incomplete coherent set. Such samples are reported as lost, with the reason LOST_BY_INCOMPLETE_COHERENT_SET, in the <a href="#">40.7.7 SAMPLE_LOST Status on page 636</a>.</li> </ul> <p>Note that a coherent set is also considered incomplete if some of its samples are filtered by content or time on the <i>DataWriter</i> side.</p> <p>Samples from an incomplete coherent set have <code>incomplete_coherent_set</code> in the <b>coherent_set_info</b> field in the <a href="#">41.6 The SampleInfo Structure on page 676</a> set to TRUE.</p>

## 46.6.1 Coherent Access

A 'coherent set' is a set of DDS data-sample modifications that must be propagated in such a way that they are interpreted at the receiver's side as a consistent set; that is, the receiver will only be able to access the data after all the modifications in the set are available at the subscribing end.

Coherency enables a publishing application to change the value of several data-instances and have those changes be seen atomically (as a cohesive set) by the readers.

Setting *coherent\_access* to TRUE only behaves as described in the DDS specification when the *DataWriter* and *DataReader* are configured for *reliable* delivery. Non-reliable *DataReaders* will never receive DDS samples that belong to a coherent set.

To send a coherent set of DDS data samples, the publishing application uses the *Publisher's* **begin\_coherent\_changes()** and **end\_coherent\_changes()** operations (see [31.10 Writing Coherent Sets of DDS Data Samples on page 417](#)).

If *coherent\_access* is TRUE, then the *access\_scope* controls the maximum extent of the coherent changes, as follows:

- If *access\_scope* is INSTANCE, the behavior is the same as TOPIC.
- If *access\_scope* is TOPIC, then coherent changes done by a *DataWriter* (indicated by their enclosure within calls to **begin\_coherent\_changes()** and **end\_coherent\_changes()**) will be made available as a unit to each remote *DataReader* independently. That is, changes made to instances within each individual *DataWriter* will be presented as a unit. They will not be grouped with changes made to instances belonging to a different *DataWriter*.
- If *access\_scope* is GROUP, coherent changes made to instances through a set of *DataWriters* attached to a common *Publisher* are presented as a unit to the *DataReaders* within a *Subscriber*.

## 46.6.2 Ordered Access

If *ordered\_access* is TRUE, then *access\_scope* controls the scope of the order in which DDS samples are presented to the subscribing application, as follows:

- If *access\_scope* is INSTANCE, the relative order of DDS samples sent by a *DataWriter* is only preserved on a per-instance basis. If two DDS samples refer to the same instance (identified by *Topic* and a particular value for the key) then the order in which they are stored in the *DataReader's* queue is consistent with the order in which the changes occurred. However, if the two DDS samples belong to different instances, the order in which they are presented may or may not match the order in which the changes occurred.
- If *access\_scope* is TOPIC, the relative order of DDS samples sent by a *DataWriter* is preserved for all DDS samples of all instances. The coherent grouping and/or order in which DDS samples appear in the *DataReader's* queue is consistent with the grouping/order in which the changes occurred in that *DataWriter*—even if the DDS samples affect different instances.
- If *access\_scope* is GROUP, the scope spans all instances belonging to *DataWriters* within the same *Publisher*—even if they are instances of different topics. Changes made to instances via *DataWriters* attached to the same *Publisher* are presented to the *DataReaders* within a *Subscriber* in the same order in which they occurred.

- If *access\_scope* is HIGHEST\_OFFERED, the *Subscriber* will use the access scope specified by each remote *Publisher*.

If the *Subscriber's* **access\_scope** is GROUP or HIGHEST\_OFFERED and **ordered\_access** is TRUE, the application is required to use the *Subscriber's* **begin\_access()** and **end\_access()** operations to access the DDS samples in order across *DataWriters* of the same group (a *Publisher* with **access\_scope** of GROUP). If you do not use these operations, the data may not be ordered across *DataWriters*. See [39.5 Beginning and Ending Group-Ordered Access on page 609](#) for additional details.

Ultimately, the data stored in the *DataReader* queue is accessed by the *DataReader's* **read()/take()** APIs. The application does not have to access the DDS data samples in the order indicated by the combination of **access\_scope** and **ordered\_access**. How the application actually gets the data from the *DataReader* is ultimately under the control of the user code. See [Chapter 41 Using DataReaders to Access Data \(Read & Take\) on page 663](#) for additional details.

### 46.6.3 Example

Coherency is useful in cases where the grouping matters across multiple *Topics* of a single *Publisher*. For example, consider an "Aircraft State" *Publisher* with two *DataWriters*, one for a *Topic* representing the altitude and the other for a *Topic* representing the velocity vector. If both altitude and velocity are changed for a given aircraft in the producer application, it may be significant to communicate those values in a way the reader can see both together as a group; otherwise, a consumer application may, for example, erroneously interpret that an aircraft is on a collision course.

Ordered access is useful when you need to ensure that DDS samples appear on the *DataReader's* queue in the order sent by one or multiple *DataWriters* within the same *Publisher*.

To illustrate the effect of the PRESENTATION QoSPolicy with TOPIC and INSTANCE access scope, assume the following sequence of DDS samples was written by the *DataWriter*: {A1, B1, C1, A2, B2, C2}. In this example, A, B, and C represent different instances (i.e., different keys). Assume all of these DDS samples have been propagated to the *DataReader's* history queue before your application invokes the **read()** operation. The DDS data-sample sequence returned depends on how the PRESENTATION QoS is set, as shown in [Table 46.9 Effect of ordered\\_access for access\\_scope INSTANCE and TOPIC](#).

Table 46.9 Effect of `ordered_access` for `access_scope` INSTANCE and TOPIC

PRESENTATION QoS	Sequence retrieved via “read()”. Order sent was {A1, B1, C1, A2, B2, C2}
<code>ordered_access = FALSE</code> <code>access_scope = &lt;any&gt;</code>	Any order is possible. For example, {A1,A2,B1,B2,C1,C2}, {A1, B1, C1, A2, B2, C2}, and {C1,B2,A1,A2,B1,C2}
<code>ordered_access = TRUE</code> <code>access_scope = INSTANCE</code>	Order is preserved per instance. Multiple orders are possible. For example, {A1,A2,B1,B2,C1,C2} or {A1, B1, C1, A2, B2, C2} or {B1,B2,A1,A2,C1,C2} Recall that <i>coherent_access</i> by INSTANCE does not apply, but <i>ordered_access</i> by INSTANCE does. So for any given instance, the samples are ordered (B1 must come before B2, for example), but <i>Connex</i> t does not need to deliver all changes to the instance atomically.
<code>ordered_access = TRUE</code> <code>access_scope = TOPIC</code>	{A1, B1, C1, A2, B2, C2}

To illustrate the effect of a PRESENTATION QoSPolicy with GROUP *access\_scope*, assume the following sequence of DDS samples was written by two *DataWriters*, W1 and W2, within the same *Publisher*: {(W1,A1), (W2,B1), (W1,C1), (W2,A2), (W1,B2), (W2,C2)}. As in the previous example, A, B, and C represent different instances (i.e., different keys). With *access\_scope* set to INSTANCE or TOPIC, the middleware cannot guarantee that the application will receive the DDS samples in the same order they were published by W1 and W2. With *access\_scope* set to GROUP, the middleware is able to provide the DDS samples in order to the application as long as the **read()/take()** operations are invoked within a **begin\_access()/end\_access()** block (see [39.5 Beginning and Ending Group-Ordered Access on page 609](#)).

**Table 46.10 Effect of `ordered_access` for `access_scope` GROUP**

PRESENTATION QoS	Sequence retrieved via “read()”. Order sent was {(W1,A1), (W2,B1), (W1,C1), (W2,A2), (W1,B2), (W2,C2)}
<code>ordered_access = FALSE</code> or <code>access_scope = TOPIC or INSTANCE</code>	The order across <i>DataWriters</i> will not be preserved. DDS samples may be delivered in multiple orders. For example: {(W1,A1), (W1,C1), (W1,B2), (W2,B1), (W2,A2), (W2,C2)} {(W1,A1), (W2,B1), (W1,B2), (W1,C1), (W2,A2), (W2,C2)}
<code>ordered_access = TRUE</code> <code>access_scope = GROUP</code>	DDS samples are delivered in the same order they were published: {(W1,A1), (W2,B1), (W1,C1), (W2,A2), (W1,B2), (W2,C2)}

## 46.6.4 Properties

This QoS Policy cannot be modified after the *Publisher* or *Subscriber* is enabled.

This QoS must be set compatibly between the *DataWriter’s Publisher* and the *DataReader’s Subscriber*. The compatible combinations are shown in [Table 46.11 Valid Combinations of `ordered\_access` and `access\_scope`, with Subscriber’s `ordered\_access = False`](#) and [Table 46.12 Valid Combinations of `ordered\_access` and `access\_scope`, with Subscriber’s `ordered\_access = True`](#) for `ordered_access` and [Table 46.13 Valid Combinations of Presentation Coherent Access and Access Scope for `coherent\_access`](#).

**Table 46.11 Valid Combinations of `ordered_access` and `access_scope`, with Subscriber’s `ordered_access = False`**

{ <code>ordered_access/access_scope</code> }		Subscriber Requests:			
		False/Instance	False/Topic	False/Group	False/Highest
Publisher offers:	False/Instance	compatible	incompatible	incompatible	compatible
	False/Topic	compatible	compatible	incompatible	compatible
	False/Group	compatible	compatible	compatible	compatible
	True/Instance	compatible	incompatible	incompatible	compatible
	True/Topic	compatible	compatible	incompatible	compatible
	True/Group	compatible	compatible	compatible	compatible

**Table 46.12 Valid Combinations of ordered\_access and access\_scope, with Subscriber's ordered\_access = True**

## 47.1 AVAILABILITY QoS Policy (DDS Extension)

This QoS policy configures the availability of data and it is used in the context of two features:

- Collaborative DataWriters ([47.1.1 Availability QoS Policy and Collaborative DataWriters on the next page](#))
- Required Subscriptions ([47.1.2 Availability QoS Policy and Required Subscriptions on page 771](#))

It contains the members listed in [Table 47.1 DDS\\_AvailabilityQoS Policy](#).

**Table 47.1 DDS\_AvailabilityQoS Policy**

Type	Field Name	Description
DDS_Boolean	enable_required_subscriptions	Enables support for required subscriptions in a <i>DataWriter</i> . If set to TRUE, history <b>kind</b> must be KEEP_ALL and durability <b>writer_depth</b> must be left set to AUTO. For Collaborative DataWriters: Not applicable. For Required Subscriptions: See <a href="#">Table 47.4 Configuring Required Subscriptions with DDS_AvailabilityQoS Policy</a> .
struct DDS_Duration_t	max_data_availability_waiting_time	Defines how much time to wait before delivering a DDS sample to the application without having received some of the previous DDS samples. For Collaborative DataWriters: See <a href="#">Table 47.3 Configuring Collaborative DataWriters with DDS_AvailabilityQoS Policy</a> . For Required Subscriptions: Not applicable.

Table 47.1 DDS\_AvailabilityQoSPolicy

Type	Field Name	Description
struct DDS_Duration_t	max_endpoint_availability_waiting_time	Defines how much time to wait to discover <i>DataWriters</i> providing DDS samples for the same data source. For Collaborative <i>DataWriters</i> : See <a href="#">Table 47.3 Configuring Collaborative DataWriters with DDS_AvailabilityQoSPolicy</a> . For Required Subscriptions: Not applicable.
struct DDS_EndpointGroupSeq	required_matched_endpoint_groups	A sequence of endpoint groups, described in <a href="#">Table 47.2 struct DDS_EndpointGroup_t</a> . For Collaborative <i>DataWriters</i> : See <a href="#">Table 47.3 Configuring Collaborative DataWriters with DDS_AvailabilityQoSPolicy</a> . For Required Subscriptions: See <a href="#">Table 47.4 Configuring Required Subscriptions with DDS_AvailabilityQoSPolicy</a>

Table 47.2 struct DDS\_EndpointGroup\_t

Type	Field Name	Description
char *	role_name	Defines the role name of the endpoint group. If used in the AvailabilityQoSPolicy on a <i>DataWriter</i> , it specifies the name that identifies a Required Subscription.
int	quorum_count	Defines the minimum number of members that satisfies the endpoint group. If used in the AvailabilityQoSPolicy on a <i>DataWriter</i> , it specifies the number of <i>DataReaders</i> with a specific role name that must acknowledge a DDS sample before the DDS sample is considered to be acknowledged by the Required Subscription.

## 47.1.1 Availability QoS Policy and Collaborative DataWriters

The *Collaborative DataWriters* feature allows you to have multiple *DataWriters* publishing DDS samples from a common logical data source. The *DataReaders* will combine the DDS samples coming from the *DataWriters* in order to reconstruct the correct order at the source. The Availability QoSPolicy allows you to configure the DDS sample combination (synchronization) process in the *DataReader*.

Each DDS sample published in a DDS domain for a given logical data source is uniquely identified by a pair (virtual GUID, virtual sequence number). DDS samples from the same data source (same virtual GUID) can be published by different *DataWriters*.

A *DataReader* will deliver a DDS sample (VGUID<sub>n</sub>, VSN<sub>m</sub>) to the application if one of the following conditions is satisfied:

- (GUID<sub>n</sub>, SN<sub>m-1</sub>) has already been delivered to the application.
- All the known *DataWriters* publishing VGUID<sub>n</sub> have announced that they do not have (VGUID<sub>n</sub>, VSN<sub>m-1</sub>).

- None of the known *DataWriters* publishing VGUIDn have announced potential availability of (VGUIDn, VSNm-1) and both timeouts in this QoS policy have expired.

A *DataWriter* announces potential availability of DDS samples by using virtual heartbeats. The frequency at which virtual heartbeats are sent is controlled by the protocol parameters [virtual\\_heartbeat\\_period on page 791](#) and [samples\\_per\\_virtual\\_heartbeat on page 791](#) (see [Table 47.14 DDS\\_RtpsReliableWriterProtocol\\_t](#)).

[Table 47.3 Configuring Collaborative DataWriters with DDS\\_AvailabilityQoSPolicy](#) describes the fields of this policy when used for a Collaborative *DataWriter*.

For further information, see [Collaborative DataWriters \(Maintain Global, Ordered Set of Samples\) \(Chapter 37 on page 588\)](#).

**Table 47.3 Configuring Collaborative DataWriters with DDS\_AvailabilityQoSPolicy**

Field Name	Description for Collaborative DataWriters
max_data_availability_waiting_time	<p>Defines how much time to wait before delivering a DDS sample to the application without having received some of the previous DDS samples.</p> <p>A DDS sample identified by (VGUIDn, VSNm) will be delivered to the application if this timeout expires for the DDS sample and the following two conditions are satisfied:</p> <p>None of the known <i>DataWriters</i> publishing VGUIDn have announced potential availability of (VGUIDn, VSNm-1).</p> <p>The <i>DataWriters</i> for all the endpoint groups specified in <a href="#">required_matched_endpoint_groups on the previous page</a> have been discovered or <a href="#">max_endpoint_availability_waiting_time on the next page</a> has expired.</p>
max_endpoint_availability_waiting_time	<p>Defines how much time to wait to discover <i>DataWriters</i> providing DDS samples for the same data source.</p> <p>The set of endpoint groups that are required to provide DDS samples for a data source can be configured using <a href="#">required_matched_endpoint_groups on the previous page</a>.</p> <p>A non-consecutive DDS sample identified by (GUIDn, SNm) cannot be delivered to the application unless the <i>DataWriters</i> for all the endpoint groups in <a href="#">required_matched_endpoint_groups on the previous page</a> are discovered or this timeout expires.</p>
required_matched_endpoint_groups	<p>Specifies the set of endpoint groups that are expected to provide DDS samples for the same data source.</p> <p>The quorum count in a group represents the number of <i>DataWriters</i> that must be discovered for that group before the <i>DataReader</i> is allowed to provide non consecutive DDS samples to the application.</p> <p>A <i>DataWriter</i> becomes a member of an endpoint group by configuring the <b>role_name</b> in the <i>DataWriter's</i> <a href="#">47.11 ENTITY_NAME QoSPolicy (DDS Extension) on page 817</a>.</p> <p>The <i>DataWriters</i> created by <i>RTI Persistence Service</i> have a predefined <b>role_name</b> of 'PERSISTENCE_SERVICE'. For other <i>DataWriters</i>, the <b>role_name</b> is not set by default.</p>

## 47.1.2 Availability QoS Policy and Required Subscriptions

In the context of Required Subscriptions, the Availability QoSPolicy can be used to configure a set of required subscriptions on a *DataWriter*.

*Required Subscriptions* are preconfigured, named subscriptions that may leave and subsequently rejoin the network from time to time, at the same or different physical locations. Any time a required sub-

scription is disconnected, any DDS samples that would have been delivered to it are stored for delivery if and when the subscription rejoins the network.

[Table 47.4 Configuring Required Subscriptions with DDS\\_AvailabilityQosPolicy](#) describes the fields of this policy when used for a Required Subscription.

For further information, see [31.13 Required Subscriptions on page 424](#).

**Table 47.4 Configuring Required Subscriptions with DDS\_AvailabilityQosPolicy**

Field Name	Description for Required Subscriptions
enable_required_subscriptions	Enables support for Required Subscriptions in a <i>DataWriter</i> . If set to TRUE, the <a href="#">47.12 HISTORY QosPolicy on page 818</a> <b>kind</b> must be KEEP_ALL, because not all samples can be guaranteed to be delivered to the required <i>DataReaders</i> if history <b>kind</b> is KEEP_LAST. Likewise, the <a href="#">47.9 DURABILITY QosPolicy on page 809</a> <b>writer_depth</b> must be left set to AUTO, because not all samples can be guaranteed to be delivered to the required <i>DataReaders</i> when <b>writer_depth</b> is limited.
max_data_availability_waiting_time	Not applicable to Required Subscriptions.
max_endpoint_availability_waiting_time	
required_matched_endpoint_groups	A sequence of endpoint groups that specify the Required Subscriptions on a <i>DataWriter</i> . Each Required Subscription is specified by a name and a quorum count. The quorum count represents the number of <i>DataReaders</i> that have to acknowledge the DDS sample before it can be considered fully acknowledged for that Required Subscription. A <i>DataReader</i> is associated with a Required Subscription by configuring the <b>role_name</b> in the <i>DataReader</i> 's <a href="#">47.11 ENTITY_NAME QosPolicy (DDS Extension) on page 817</a> .

### 47.1.3 Properties

For *DataWriters*, all the members in this QosPolicy can be changed after the *DataWriter* is created except for the member **enable\_required\_subscriptions**.

For *DataReaders*, this QosPolicy cannot be changed after the *DataReader* is created.

There are no compatibility restrictions for how it is set on the publishing and subscribing sides.

### 47.1.4 Related QosPolicies

- [47.11 ENTITY\\_NAME QosPolicy \(DDS Extension\) on page 817](#)
- [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 714](#)
- [47.9 DURABILITY QosPolicy on page 809](#)

## 47.1.5 Applicable DDS Entities

- [Chapter 31 DataWriters on page 389](#)
- [Chapter 40 DataReaders on page 615](#)

## 47.1.6 System Resource Considerations

The resource limits for the endpoint groups in **required\_matched\_endpoint\_groups** are determined by two values in the [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 714](#):

- **max\_endpoint\_groups**
- **max\_endpoint\_group\_cumulative\_characters**

The maximum number of virtual writers (identified by a virtual GUID) that can be managed by a *DataReader* is determined by the **max\_remote\_virtual\_writers** in [48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 876](#). When the *Subscriber's* **access\_scope** is GROUP, **max\_remote\_virtual\_writers** determines the maximum number of *DataWriter* groups supported by the *Subscriber*. Since the *Subscriber* may contain more than one *DataReader*, only the setting of the first applies.

## 47.2 BATCH QosPolicy (DDS Extension)

This QosPolicy can be used to decrease the amount of communication overhead associated with the transmission and (in the case of reliable communication) acknowledgment of small DDS samples, in order to increase throughput.

It specifies and configures the mechanism that allows *Connex* to collect multiple user data DDS samples to be sent in a single network packet, to take advantage of the efficiency of sending larger packets and thus increase effective throughput.

This QosPolicy can be used to increase effective throughput dramatically for small data DDS samples. Throughput for small DDS samples (size < 2048 bytes) is typically limited by CPU capacity and not by network bandwidth. Batching many smaller DDS samples to be sent in a single large packet will increase network utilization and thus throughput in terms of DDS samples per second.

It contains the members listed in [Table 47.5 DDS\\_BatchQosPolicy](#).

Table 47.5 DDS\_BatchQoSPolicy

Type	Field Name	Description
DDS_Boolean	enable	Enables/disables batching.
DDS_Long	max_data_bytes	Sets the maximum cumulative length of all serialized DDS samples in a batch. Before or when this limit is reached, the batch is automatically flushed. The size does not include the meta-data associated with the batch DDS samples.
DDS_Long	max_samples	Sets the maximum number of DDS samples in a batch. When this limit is reached, the batch is automatically flushed.
struct DDS_Duration_t	max_flush_delay	Sets the maximum flush delay. When this duration is reached, the batch is automatically flushed. The delay is measured from the time the first DDS sample in the batch is written by the application.
struct DDS_Duration_t	source_timestamp_resolution	Sets the batch source timestamp resolution. The value of this field determines how the source timestamp is associated with the DDS samples in a batch. A DDS sample written with timestamp 't' inherits the source timestamp 't2' associated with the previous DDS sample, unless ('t' - 't2') is greater than <b>source_timestamp_resolution</b> . If <b>source_timestamp_resolution</b> is DURATION_INFINITE, every DDS sample in the batch will share the source timestamp associated with the first DDS sample. If <b>source_timestamp_resolution</b> is zero, every DDS sample in the batch will contain its own source timestamp corresponding to the moment when the DDS sample was written. The performance of the batching process is better when <b>source_timestamp_resolution</b> is set to DURATION_INFINITE.
DDS_Boolean	thread_safe_write	Determines whether or not the write operation is thread-safe. If TRUE, multiple threads can call write on the <i>DataWriter</i> concurrently. A setting of FALSE can be used to increase batching throughput for batches with many small DDS samples.

If batching is enabled (not the default), DDS samples are not immediately sent when they are written. Instead, they get collected into a "batch." A batch always contains whole number of DDS samples—a DDS sample will never be fragmented into multiple batches.

A batch is sent on the network ("flushed") when one of the following things happens:

- User-configurable flushing conditions
  - A batch size limit (**max\_data\_bytes**) is reached.
  - A number of DDS samples are in the batch (**max\_samples**).
  - A time-limit (**max\_flush\_delay**) is reached, as measured from the time the first DDS sample in the batch is written by the application.
  - The application explicitly calls a *DataWriter's flush()* operation.

- Non-user configurable flushing conditions:
  - A coherent set starts or ends.
  - The number of DDS samples in the batch is equal to **max\_samples** in RESOURCE\_LIMITS for unkeyed topics or **max\_samples\_per\_instance** in RESOURCE\_LIMITS for keyed topics.

Additional batching configuration takes place in the *Publisher's* [46.1 ASYNCHRONOUS\\_PUBLISHER QosPolicy \(DDS Extension\)](#) on page 740.

The **flush()** operation is described in [31.9 Flushing Batches of DDS Data Samples](#) on page 416.

## 47.2.1 Synchronous and Asynchronous Flushing

Usually, a batch is flushed synchronously:

- When a batch reaches its application-defined size limit (**max\_data\_bytes** or **max\_samples**) because the application called **write()**, the batch is flushed immediately in the context of the writing thread.
- When an application manually flushes a batch, the batch is flushed immediately in the context of the calling thread.
- When the first DDS sample in a coherent set is written, the batch in progress (without including the DDS sample in the coherent set) is immediately flushed in the context of the writing thread.
- When a coherent set ends, the batch in progress is immediately flushed in the context of the calling thread.
- When the number of DDS samples in a batch is equal to **max\_samples** in RESOURCE\_LIMITS for unkeyed topics or **max\_samples\_per\_instance** in RESOURCE\_LIMITS for keyed topics, the batch is flushed immediately in the context of the writing thread.

However, some behavior is asynchronous:

- To flush batches based on a time limit (**max\_flush\_delay**), enable asynchronous batch flushing in the [46.1 ASYNCHRONOUS\\_PUBLISHER QosPolicy \(DDS Extension\)](#) on page 740 of the *DataWriter's Publisher*. This will cause the *Publisher* to create an additional thread that will be used to flush batches of that *Publisher's DataWriters*. This behavior is analogous to the way asynchronous publishing works.
- You may also use batching alongside asynchronous publication with [34.4 FlowControllers \(DDS Extension\)](#) on page 532. These features are independent of one another. Flushing a batch on an asynchronous *DataWriter* makes it available for sending to the *DataWriter's* FlowController. From the point of view of the FlowController, a batch is treated like one large DDS sample.

## 47.2.2 Batching vs. Coalescing

Even when batching is disabled, *Connex* will sometimes coalesce multiple DDS samples into a single network datagram. For example, DDS samples buffered by a FlowController or sent in response to a negative acknowledgement (NACK) may be coalesced. This behavior is distinct from DDS sample batching.

DDS samples that are sent individually (not part of a batch) are always treated as separate DDS samples by *Connex*. Each DDS sample is accompanied by a complete RTPS header on the network (although DDS samples may share UDP and IP headers) and (in the case of reliable communication) a unique physical sequence number that must be positively or negatively acknowledged.

In contrast, batched DDS samples share an RTPS header and an entire batch is acknowledged—positively or negatively—as a unit, potentially reducing the amount of meta-traffic on the network and the amount of processing per individual DDS sample.

Batching can also improve latency relative to simply coalescing. Consider two use cases:

1. A *DataWriter* is configured to write asynchronously with a FlowController. Even if the FlowController's rules would allow it to publish a new DDS sample immediately, the send will always happen in the context of the asynchronous publishing thread. This context switch can add latency to the send path.
2. A *DataWriter* is configured to write synchronously but with batching turned on. When the batch is full, it will be sent on the wire immediately, eliminating a thread context switch from the send path.

## 47.2.3 Batching and ContentFilteredTopics

When batching is enabled, content filtering is always done on the reader side.

## 47.2.4 Turbo Mode: Automatically Adjusting the Number of Bytes in a Batch—Experimental Feature

*Turbo Mode* is an experimental feature that uses an intelligent algorithm that automatically adjusts the number of bytes in a batch at run time according to current system conditions, such as write speed (or write frequency) and DDS sample size. This intelligence is what gives it the ability to increase throughput at high message rates and avoid negatively impacting message latency at low message rates.

To enable Turbo mode, set the *DataWriter's* property `dds.data_writer.enable_turbo_mode` to true. Turbo mode is not enabled by default.

**Note:** If you explicitly enable batching by setting `enable` to `TRUE` in `BatchQosPolicy`, the value of the turbo mode property is ignored and turbo mode is not used.

## 47.2.5 Performance Considerations

The purpose of batching is to increase throughput when writing small DDS samples at a high rate. In such cases, throughput can be increased several-fold, approaching much more closely the physical limitations of the underlying network transport.

However, collecting DDS samples into a batch implies that they are not sent on the network immediately when the application writes them; this can potentially increase latency. However, if the application sends data faster than the network can support, an increased proportion of the network's available bandwidth will be spent on acknowledgements and DDS sample resends. In this case, reducing that overhead by turning on batching could decrease latency while increasing throughput.

As a general rule, to improve batching throughput:

- Set **thread\_safe\_write** to `FALSE` when the batch contains a big number of small DDS samples. If you do not use a thread-safe write configuration, asynchronous batch flushing must be disabled.
- Set **source\_timestamp\_resolution** to `DURATION_INFINITE`. Note that you set this value, every DDS sample in the batch will share the same source timestamp.

Batching affects how often piggyback heartbeats are sent; see **heartbeats\_per\_max\_samples** in [Table 47.14 DDS\\_RtpsReliableWriterProtocol\\_t](#).

## 47.2.6 Maximum Transport Datagram Size

Batches cannot be fragmented. As a result, the maximum batch size (**max\_data\_bytes**) must be set no larger than the maximum transport datagram size. For example, a UDP datagram is limited to 64 KB, so any batches sent over UDP must be less than or equal to that size.

## 47.2.7 Bandwidth Considerations

A minimum overhead of 8-bytes is added to each sample in a batch; however, the overhead may be bigger in some cases. For example:

- When you add a source timestamp per sample instead of per batch, there will be 8 more bytes for the source timestamp. You can control this behavior with **writer\_qos.batch.source\_timestamp\_resolution**.
- By default, for keyed topics, *Connex* adds the key hash for the instance, adding an extra overhead of 20 bytes. If you don't want to add the key hash and instead get it from the serialized data on the *DataReader* side, set **writer\_qos.protocol.disable\_inline\_keyhash** to true.
- Disposed/unregistered samples also need an additional 8-byte overhead to mark the status as disposed or unregistered.

- There are other scenarios in which overhead may increase—for example, when using collaborative *DataWriters* or group order access.

To summarize:

- For a data sample for a keyed topic, by default, the overhead will be 32-bytes (8 (minimum) + 20 (for the key hash) + 4 (for the sentinel)). You can reduce this to 8 bytes by not sending the key hash (in which case, the sentinel goes away, too).
- For disposed/unregistered samples for a keyed topic, by default, the overhead will be 40-bytes (8 (minimum) + 20 (for the key hash) + 8 (for the status information) + 4 (for the sentinel)). You can reduce this to 20 bytes by not sending the key hash (the sentinel remains for the status information).
- For an unkeyed topic, the overhead is typically 8 bytes.

## 47.2.8 Properties

This QosPolicy cannot be modified after the *DataWriter* is enabled.

Since it is only for *DataWriters*, there are no compatibility restrictions for how it is set on the publishing and subscribing sides.

*All batching configuration occurs on the publishing side.* A subscribing application does not configure anything specific to receive batched DDS samples, and in many cases, it will be oblivious to whether the DDS samples it processes were received individually or as part of a batch.

Consistency rules:

- **max\_samples** must be consistent with **max\_data\_bytes**: they cannot both be set to LENGTH\_UNLIMITED.
- If **max\_flush\_delay** is not DURATION\_INFINITE, **disable\_asynchronous\_batch** in the [46.1 ASYNCHRONOUS\\_PUBLISHER QosPolicy \(DDS Extension\) on page 740](#) must be FALSE.
- If **thread\_safe\_write** is FALSE, **source\_timestamp\_resolution** must be DURATION\_INFINITE.

## 47.2.9 Related QosPolicies

To flush batches based on a time limit, enable batching in the [46.1 ASYNCHRONOUS\\_PUBLISHER QosPolicy \(DDS Extension\) on page 740](#) of the *DataWriter's Publisher*.

Be careful when configuring a *DataWriter's* [47.14 LIFESPAN QoS Policy on page 824](#) with a **duration** shorter than the batch flush period (**max\_flush\_delay**). If the batch does not fill up before the flush period elapses, by default the short **duration** will cause the DDS samples to be dropped without being sent. (You can, however, change this default behavior. See the last paragraph in this section.)

Do not configure the *DataReader's* or *DataWriter's* [47.12 HISTORY QoS Policy on page 818](#) to be shallower than the *DataWriter's* maximum batch size (**max\_samples**). When the HISTORY QoS Policy is shallower on the *DataWriter*, by default some DDS samples may not be sent. (You can, however, change this default behavior. See the last paragraph in this section.) When the HISTORY QoS Policy is shallower on the *DataReader*, DDS samples may be lost before being provided to the application.

The initial and maximum numbers of batches that a *DataWriter* will manage is set in the [47.6 DATA\\_WRITER\\_RESOURCE\\_LIMITS QoS Policy \(DDS Extension\) on page 800](#).

The maximum number of DDS samples that a *DataWriter* can store is determined by the value **max\_samples** in the [47.22 RESOURCE\\_LIMITS QoS Policy on page 850](#) and **max\_batches** in the [47.6 DATA\\_WRITER\\_RESOURCE\\_LIMITS QoS Policy \(DDS Extension\) on page 800](#). The limit that is reached first is applied.

The amount of resources required for batching depends on the configuration of the [47.22 RESOURCE\\_LIMITS QoS Policy on page 850](#) and the [47.6 DATA\\_WRITER\\_RESOURCE\\_LIMITS QoS Policy \(DDS Extension\) on page 800](#). See [47.2.11 System Resource Considerations](#) below.

By default, samples marked as removed in a batch are dropped. Examples of removed samples in a batch are samples that were replaced due to **KEEP\_LAST\_HISTORY\_QOS** on the *DataWriter* (see [47.12 HISTORY QoS Policy on page 818](#)) or samples that outlived the *DataWriter's* [47.14 LIFESPAN QoS Policy on page 824](#) duration. You can keep track of the number of these dropped samples via **writer\_removed\_batch\_sample\_dropped\_sample\_count** in the [40.7.2 DATA\\_READER\\_CACHE\\_STATUS on page 627](#). You can also choose not to drop these samples at all by setting the property **dds.data\_reader.accept\_writer\_removed\_batch\_samples** to TRUE (by default it is set to FALSE); you can set this property via the [47.19 PROPERTY QoS Policy \(DDS Extension\) on page 837](#).

**Note:** When the *DataWriter* history depth is shallower than the *DataWriter's* maximum batch size (**max\_samples**), the excess samples are marked as removed, but you can choose *not* to drop these removed samples using the **accept\_writer\_removed\_batch\_samples** property. But when the *DataReader* history depth is shallower than the *DataWriter's* maximum batch size (**max\_samples**), the excess samples are lost. (These are not affected by the property or included in the dropped sample count.)

## 47.2.10 Applicable DDS Entities

- [Chapter 31 DataWriters on page 389](#)

## 47.2.11 System Resource Considerations

- Batching requires additional resources to store the meta-data associated with the DDS samples in the batch.
  - For unkeyed topics, the meta-data will be at least 8 bytes, with a maximum of 20 bytes.
  - For keyed topics, the meta-data will be at least 8 bytes, with a maximum of 52 bytes.

- Other resource considerations are described in [47.2.9 Related QosPolicies on page 778](#).

## 47.3 DATA\_REPRESENTATION QosPolicy

The DATA\_REPRESENTATION QosPolicy is used to configure what form data is represented or expected in on the wire. It indicates which versions (version 1 and version 2) of the Extended Common Data Representation (CDR) are offered and requested as well as if and how the data may be compressed, including which compression algorithm is offered and requested.

A *DataWriter* offers a single representation, which indicates the CDR version the *DataWriter* uses to serialize its data. A *DataReader* requests one or more representations, which indicate the CDR versions the *DataReader* accepts. If a *DataWriter*'s offered representation is contained within a reader's sequence of requested representations, then the offer satisfies the request, and the policies are compatible. Otherwise, they are incompatible. See [Table 47.6 DDS\\_DataRepresentationQosPolicy](#) and [47.3.1 Data Representation on the next page](#) for more information.

A *DataWriter* also offers a single **compression\_ids** value, which is the compression algorithm the *DataWriter* uses to compress data it sends to matching *DataReaders*. A *DataReader* requests zero or more compression algorithms. If a *DataWriter* offers a compression algorithm that is contained within the algorithms requested by the *DataReader*, the offer satisfies the request and the policies are compatible. Otherwise, they are incompatible. See [Table 47.6 DDS\\_DataRepresentationQosPolicy](#) and [47.3.2 Data Compression on page 782](#) for more information.

The DATA\_REPRESENTATION QosPolicy includes the members in [Table 47.6 DDS\\_DataRepresentationQosPolicy](#). For defaults and valid ranges, please refer to the API Reference HTML documentation.

Table 47.6 DDS\_DataRepresentationQoSPolicy

Type	Field Name	Description
DDS_DataRepresentationIdSeq	value	<p>A sequence of two-byte signed integers corresponding to representation identifiers. The supported identifiers are DDS_XCDR_DATA_REPRESENTATION (Extensible CDR version 1), DDS_XCDR2_DATA_REPRESENTATION (Extensible CDR version 2), and DDS_AUTO_DATA_REPRESENTATION. An empty sequence is equivalent to a sequence with one DDS_XCDR_DATA_REPRESENTATION element. The default value, however, is a sequence with one DDS_AUTO_DATA_REPRESENTATION element.</p> <p>For plain language binding, the value DDS_AUTO_DATA_REPRESENTATION translates to DDS_XCDR_DATA_REPRESENTATION if the @allowed_data_representation annotation either is not specified or contains the value XCDR. Otherwise, it translates to DDS_XCDR2_DATA_REPRESENTATION. For FlatData language binding, DDS_AUTO_DATA_REPRESENTATION translates to XCDR2_DATA_REPRESENTATION. (See <a href="#">47.3.1 Data Representation</a> below for further explanation.)</p> <p>For additional information on the @allowed_data_representation annotation, see <i>Data Representation</i>, in the <a href="#">RTI Connext Core Libraries Extensible Types Guide</a>.</p>
DDS_CompressionSettings_t	compression_settings	<p>Settings related to compressing user data:</p> <ul style="list-style-type: none"> <li> <p><b>compression_ids:</b> A bitmap that represents the compression algorithm IDs supported by the <i>DataWriter</i> or <i>DataReader</i>. The possible values are: ZLIB, BZIP2, LZ4, MASK_NONE, and MASK_ALL.</p> <p>Only ZLIB is supported if the <i>DataWriter</i> is using both compression and batching. See <a href="#">47.3.2 Data Compression</a> on the next page.</p> <p><i>DataWriter</i> creation will fail if more than one algorithm is provided on the <i>DataWriter</i> side (meaning that MASK_ALL is only supported for <i>DataReaderQoS</i> and <i>TopicQoS</i>).</p> <p>Default: MASK_NONE (for <i>DataWriterQoS</i> and <i>TopicQoS</i>), MASK_ALL (for <i>DataReaderQoS</i>)</p> </li> <li> <p><b>writer_compression_level:</b> The level of compression to use when compressing data. The value is a range between 0 and 10. It can be set only for the <i>DataWriterQoS</i> or <i>TopicQoS</i>. A lower compression level results in a faster compression speed, but lower compression ratio. A higher compression level results in a better compression ratio, but slower compression speed.</p> <p>Default: BEST_COMPRESSION (10)</p> </li> <li> <p><b>writer_compression_threshold:</b> The threshold, in bytes, above which a serialized sample is eligible to be compressed. The value is a range between 0 and LENGTH_UNLIMITED. It can be set only for the <i>DataWriterQoS</i> or <i>TopicQoS</i>.</p> <p>Any sample with a serialized size equal to or greater than the threshold will be eligible to be compressed. Only if the compressed size is smaller than the serialized size will the sample be stored and sent compressed on the wire.</p> <p>Setting the threshold to LENGTH_UNLIMITED disables compression.</p> <p>Default: COMPRESSION_THRESHOLD_DEFAULT (8192 bytes). Note: COMPRESSION_THRESHOLD_DEFAULT is not a valid value in XML, it can be set only in code.</p> </li> </ul> <p>See <a href="#">47.3.2 Data Compression</a> on the next page for more details.</p>

## 47.3.1 Data Representation

You can view data representation as a two-step process:

- As described above, DDS\_AUTO\_DATA\_REPRESENTATION translates to the value DDS\_XCDR\_DATA\_REPRESENTATION or DDS\_XCDR2\_DATA\_REPRESENTATION depending on a few factors. Or you can explicitly set the value to DDS\_XCDR\_DATA\_REPRESENTATION or DDS\_XCDR2\_DATA\_REPRESENTATION. If you let DDS\_AUTO\_

DATA\_REPRESENTATION set the value, the following table shows how it will be set, depending on your IDL:

**Table 47.7 How DDS\_AUTO\_DATA\_REPRESENTATION Sets the Value**

IDL looks like ...	AUTO value translates to ...
<pre>Struct Point { } which is equivalent to: @allowed_data_representation(XCDR   XCDR2) Struct Point { }</pre>	XCDR
<pre>@allowed_data_representation(XCDR2) Struct Point { }</pre>	XCDR2
<pre>@language_binding(FLAT_DATA) Struct Point { }</pre>	XCDR2

- Once the value is set (either by DDS\_AUTO\_DATA\_REPRESENTATION or explicitly by you), that value determines what the *DataWriter* writes or the *DataReader* reads. (Recall that the *DataWriter* offers one representation; the *DataReader* requests one or more representations.) The next step is how the *DataWriter* and *DataReader* match based on the QoS value. The QoS must be compatible between the *DataWriter* and the *DataReader*. The compatible combinations are shown in [Table 47.6 DDS\\_DataRepresentationQoSPolicy](#).

**Table 47.8 Valid Reader/Writer Combinations of DataRepresentation**

DataWriter-offered DataRepresentation value	DataReader-requested DataRepresentation values
XCDR	XCDR
XCDR	XCDR and XCDR2
XCDR2	XCDR2
XCDR2	XCDR and XCDR2

If this QoSPolicy is set incompatibly, the ON\_OFFERED\_INCOMPATIBLE\_QOS and ON\_REQUESTED\_INCOMPATIBLE\_QOS statuses will be modified and the corresponding *Listeners* called for the *DataWriter* and *DataReader* respectively.

## 47.3.2 Data Compression

A *DataReader* with compression enabled can receive samples from *DataWriters* with or without compression as well as from multiple *DataWriters* with different compression algorithms. *DataWriters* cannot optionally send compressed samples to some *DataReaders* and the same samples, but uncompressed, to other *DataReaders* that do not support compression.

Table 47.9 Valid Reader/Writer Combinations of Compression IDs shows which *DataWriters*/*DataReaders* will match depending on their compression IDs:

**Table 47.9 Valid Reader/Writer Combinations of Compression IDs**

DataWriter-offered compression_ids	DataReader-requested compression_ids					
		NONE	ZLIB	LZ4	BZIP2	MASK_ALL or any combination that includes offered <b>compression_ids</b>
NONE	compatible	compatible	compatible	compatible	compatible	compatible
ZLIB	incompatible	compatible	incompatible	incompatible	compatible	compatible
LZ4	incompatible	incompatible	compatible	incompatible	compatible	compatible
BZIP2	incompatible	incompatible	incompatible	compatible	compatible	compatible
MASK_ALL is not a valid value for the <i>DataWriter</i> , which supports only one <b>compression_ids</b> value						

### 47.3.2.1 compression\_ids

You can compare the compression algorithms (LZ4, zlib, and bzip2) by checking their compression ratios against their compression speeds. The compression ratio defines how much the data size is reduced. For example, a ratio of 2 means that the size of the data is reduced by half. The compression speed has a direct impact on the latency of the compressed data; the slower the speed, the higher the latency. Generally, the higher the compression ratio, the lower the speed; the higher the speed, the lower the compression ratio.

**Table 47.10 Compression Algorithm References**

compression_ids	Information
MASK_NONE	Default for <i>DataWriterQoS</i> and <i>TopicQoS</i>
LZ4	See <a href="https://github.com/lz4/lz4">https://github.com/lz4/lz4</a>
ZLIB	See <a href="https://zlib.net/">https://zlib.net/</a>
BZIP2	See <a href="https://www.sourceware.org/bzip2/">https://www.sourceware.org/bzip2/</a>
MASK_ALL	Default for <i>DataReaderQoS</i>

There are many benchmarking resources comparing various compression algorithms. One such resource is <https://github.com/inikep/lzbench>. LZ4 is considered the fastest of the three builtin algorithms, while zlib and bzip2 give the best compression ratios. Use LZ4 if you want to keep latency as low as possible while maintaining a decent compression ratio. Use zlib or bzip2 if latency is less important in your system than a high compression ratio to reduce bandwidth usage. The choice of which of the three builtin

compression algorithms to use depends on the type of data, the rate at which the data is being sent, and latency and bandwidth considerations. It is a good idea for you to understand the strengths and weaknesses of each of the builtin algorithms, and perform benchmarking in your own system so that you can choose the algorithm that is best suited to your system.

When you specify compression settings for a *Topic*, all *DataWriters* and *DataReaders* for that *Topic* inherit the *Topic's* compression settings. If you specify multiple compression algorithms for a *Topic*, the *DataReader* will use all of them, but since the *DataWriter* can have only one algorithm enabled, it will choose one of them, in the following order: ZLIB, BZIP2, and LZ4.

#### Notes:

- When the **serialize\_key\_with\_dispose** field in the [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 788](#) is enabled and a dispose message is sent, the serialized key is not compressed.
- The only algorithm supported when compression and batching are enabled on the same *DataWriter* is ZLIB, because zlib is the only builtin algorithm that supports stream-based compression with acceptable performance. Stream-based compression allows *Connex*t to compress and build the batch as samples are written into the batch. (LZ4 also supports stream-based compression, but with a high performance penalty, so RTI has decided not to support this mode in *Connex*t.)
- The combination of compression, batching, and data protection (via *Security Plugins*) is supported. See the "Interaction with Compression" section in the *RTI Security Plugins User's Manual* for details.

#### 47.3.2.2 writer\_compression\_level

Each level between 0 and 10 has trade-offs between compression ratio and compression speed, with 1 representing the fastest speed and lowest compression ratio and 10 representing the slowest speed and highest compression ratio. (0 disables compression.)

*Connex*t also provides the following **writer\_compression\_level** values:

- BEST\_COMPRESSION. This value is the same as 10. With this value, *Connex*t chooses the best compression level for the given algorithm.
- BEST\_SPEED. This value is the same as 1. With this value, *Connex*t chooses the fastest compression speed for whatever algorithm is chosen.

BEST\_COMPRESSION and BEST\_SPEED do not vary dynamically depending on the algorithm and the size of the data. They have a strict one-to-one mapping to the algorithms' compression ratios/speeds as follows:

- zlib

writer_compression_level	zlib mapped value
BEST_COMPRESSION = 10	level = 9
BEST_SPEED = 1	level = 1

For the rest of the values, a linear normalization is applied, so any **writer\_compression\_level** value you enter in the range of 1 to 10 is translated to the range used by ZLIB between 1 and 9. See the zlib documentation for the **compress2** function for more details on how the level parameter is used.

- LZ4

writer_compression_level	LZ4 mapped value
BEST_COMPRESSION = 10	acceleration = 0
BEST_SPEED = 1	acceleration = 30

For the rest of the values, a linear normalization is applied, so any **writer\_compression\_level** value you enter in the range of 1 to 10 is translated to the range used by LZ4 between 30 and 0. Although technically the acceleration value is unbounded, *Connex* sets the limit at 30; beyond that, no compression occurs in most cases. See the LZ4 documentation for the **LZ4\_compress\_fast** function for more details on how the acceleration parameter is used.

- bzip2

writer_compression_level	bzip2 mapped value
BEST_COMPRESSION = 10	blockSize100k = 9
BEST_SPEED = 1	blockSize100k = 1

For the rest of the values, a linear normalization is applied, so any **writer\_compression\_level** value you enter in the range of 1 to 10 is translated to the range used by bzip2 between 1 and 9. See the bzip2 documentation for the **BZ2\_bzBuffToBuffCompress** function for more details on how the blockSize100k parameter is used.

### 47.3.2.3 writer\_compression\_threshold

Any sample with a serialized size equal to or greater than this threshold (see [Table 47.6 DDS\\_DataRepresentationQosPolicy](#)) is eligible to be compressed.

There are two scenarios where a sample, even with compression enabled on the *DataWriter*, is not compressed:

- Any sample with a serialized size lower than the `writer_compression_threshold` will not be compressed.

If batching is enabled: a batch will not be compressed if the maximum serialized size of the batch (`(max_sample_serialized_size` as returned by the type-plugin `get_serialized_sample_max_size()` \* `max_samples in the batch`) is smaller than the `writer_compression_threshold`. See information about `max_samples` in [47.2 BATCH QosPolicy \(DDS Extension\) on page 773](#).

- If the compressed size is bigger than the sample's serialized size, the compressed sample will be discarded and the original sample will be sent instead.

#### 47.3.2.4 Connex Micro

*Connex Micro* does not interoperate with *DataWriters* that send compressed data.

#### 47.3.2.5 Performance Considerations when Using Content Filtering and Compression

Samples are stored compressed in the *DataWriter*'s queue. When a sample is being written and there are matching *DataReaders* using *ContentFilteredTopics*, the *DataWriter* will apply the filter and then compress the sample. In some cases, a sample needs to be filtered again after it has already been compressed. This can happen, for example, when a non-VOLATILE, late-joining *DataReader* with a *ContentFilteredTopic* is discovered by the *DataWriter* or a *TopicQuery* is issued by an existing *DataReader*. If a filtering operation occurs on the *DataWriter* side after the sample is already compressed, the sample must be decompressed to apply the filter, increasing the latency for these requested samples. Note that in these scenarios the original compressed sample is kept around, so a sample is never compressed twice. In other words, *Connex* decompresses the sample into a separate buffer, performs the filtering, and then either sends or doesn't send the compressed sample.

#### 47.3.2.6 Using Compression with FlatData language binding and Zero Copy Transfer over Shared Memory

See FlatData's section [34.1.4.2.4 Interactions with RTI Security Plugins and Compression on page 515](#) for notes about interactions with the FlatData language binding.

See Zero Copy's section [34.1.5.1.5 Interactions with RTI Security Plugins and Compression on page 522](#) for information about interactions with Zero Copy transfer over shared memory.

### 47.3.3 Properties

This *QosPolicy* cannot be modified after the Entity has been enabled.

## 47.3.4 Applicable Entities

- [18.1 Topics on page 246](#)
- [Chapter 31 DataWriters on page 389](#)
- [Chapter 40 DataReaders on page 615](#)

## 47.4 DATATAG QosPolicy

The DATATAG QosPolicy can be used to associate a set of tags in the form of (name, value) pairs with a *DataReader* or *DataWriter*. The Access Control plugin may use the tags to determine publish and subscribe permissions.

The DATATAG QosPolicy is similar to the PropertyQosPolicy, except you cannot select whether or not a particular pair should be propagated (included in the built-in topic); data tags are always propagated. For example, with the Property QoS, it would be possible for a *DomainParticipant* to allow its own endpoint (*DataReader* or *DataWriter*) based on some required properties, and for a remote *DomainParticipant* to deny that same endpoint because the endpoint chose not to propagate the required properties to the remote *DomainParticipant*. To avoid such inconsistencies—and because other participants *must* know about a *DomainParticipant*'s security credentials—data tags in the DATATAG QosPolicy are always propagated.

This policy includes the member listed in [Table 47.11 DDS\\_DataTagQosPolicy](#).

**Table 47.11 DDS\_DataTagQosPolicy**

Type	Field Name	Description
DDS_TagSeq	tags	A sequence of (name, value) string pairs.

You can manipulate the sequence of tags (name, value pairs) with the standard methods available for sequences. You can also use the helper class, *DataTagQosPolicyHelper*, which provides another way to work with a *DataTagQosPolicy* object. The *DataTagQosPolicyHelper* operations are described in the following table. For more information, see the API Reference HTML documentation.

**Table 47.12 DDS\_DataTagQosPolicyHelper Operations**

Operation	Description
get_number_of_tags	Gets the number of data tags in the input policy.
assert_tag	Asserts the data tag identified by name in the input policy. (Either adds it, or replaces an existing one.)
add_tag	Adds a new data tag to the input policy.

**Table 47.12 DDS\_DataTagQosPolicyHelper Operations**

Operation	Description
lookup_tag	Searches for a data tag in the input policy given its name.
remove_tag	Removes a data tag from the input policy.

### 47.4.1 Properties

This QosPolicy cannot be modified after the Entity has been created. There is no requirement that the publishing and subscribing sides use compatible values.

### 47.4.2 Related QosPolicies

[44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 714](#)

### 47.4.3 Applicable Entities

- [Chapter 31 DataWriters on page 389](#)
- [Chapter 40 DataReaders on page 615](#)

### 47.4.4 System Resource Considerations

[44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 714](#) contains several fields for configuring the resources associated with the data tags stored in this QosPolicy.

## 47.5 DATA\_WRITER\_PROTOCOL QosPolicy (DDS Extension)

*Connex* uses a standard protocol for packet (user and meta data) exchange between applications. The DataWriterProtocol QosPolicy gives you control over configurable portions of the protocol, including the configuration of the reliable data delivery mechanism of the protocol on a per *DataWriter* basis.

These configuration parameters control timing and timeouts, and give you the ability to trade off between speed of data loss detection and repair, versus network and CPU bandwidth used to maintain reliability.

It is important to tune the reliability protocol on a per *DataWriter* basis to meet the requirements of the end-user application so that data can be sent between *DataWriters* and *DataReaders* in an efficient and optimal manner in the presence of data loss. You can also use this QosPolicy to control how *Connex* responds to "slow" reliable *DataReaders* or ones that disconnect or are otherwise lost.

This policy includes the members presented in [Table 47.13 DDS\\_DataWriterProtocolQosPolicy](#) and [Table 47.14 DDS\\_RtpsReliableWriterProtocol\\_t](#). For defaults and valid ranges, please refer to the API Reference HTML documentation.

For details on the reliability protocol used by *Connex*, see [Reliability Models for Sending Data \(Chapter 32 on page 446\)](#). See the [47.21 RELIABILITY QosPolicy on page 845](#) for more information on *per-DataReader/DataWriter* reliability configuration. The [47.12 HISTORY QosPolicy on page 818](#) and [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#) also play important roles in the DDS reliability protocol.

**Table 47.13 DDS\_DataWriterProtocolQosPolicy**

Type	Field Name	Description
DDS_GUID_t	virtual_guid	<p>The virtual GUID (Global Unique Identifier) is used to uniquely identify the same <i>DataWriter</i> across multiple incarnations. In other words, this value allows <i>Connex</i> to remember information about a <i>DataWriter</i> that may be deleted and then re-created.</p> <p><i>Connex</i> uses the virtual GUID to associate a durable writer history to a <i>DataWriter</i>.</p> <p><i>Persistence Service</i> uses the virtual GUID to send DDS samples on behalf of the original <i>DataWriter</i>.</p> <p>A <i>DataReader</i> persists its state based on the virtual GUIDs of matching remote <i>DataWriters</i>.</p> <p>For more information, see <a href="#">21.2 Durability and Persistence Based on Virtual GUIDs on page 293</a>.</p> <p>By default, <i>Connex</i> will assign a virtual GUID automatically. If you want to restore the state of the durable writer history after a restart, you can retrieve the value of the writer's virtual GUID using the <i>DataWriter</i>'s <code>get_qos()</code> operation, and set the virtual GUID of the restarted <i>DataWriter</i> to the same value.</p>
DDS_Unsigned-Long	rtps_object_id	<p>Determines the <i>DataWriter</i>'s RTPS object ID, according to the DDS-RTPS Interoperability Wire Protocol.</p> <p>Only the last 3 bytes are used; the most significant byte is ignored.</p> <p>The <code>rtps_host_id</code>, <code>rtps_app_id</code>, and <code>rtps_instance_id</code> in the <a href="#">44.9 WIRE_PROTOCOL QosPolicy (DDS Extension) on page 730</a>, together with the 3 least significant bytes in <code>rtps_object_id</code>, and another byte assigned by <i>Connex</i> to identify the entity type, forms the <code>BuiltinTopicKey</code> in <code>PublicationBuiltinTopicData</code>.</p>
DDS_Boolean	push_on_write	<p>Controls when a DDS sample is sent after <code>write()</code> is called on a <i>DataWriter</i>. If TRUE, the DDS sample is sent immediately; if FALSE, the DDS sample is put in a queue until an ACK/NACK is received from a reliable <i>DataReader</i>.</p>
DDS_Boolean	disable_positive_acks	<p>Determines whether matching <i>DataReaders</i> send positive acknowledgements (ACKs) to the <i>DataWriter</i>.</p> <p>When TRUE, the <i>DataWriter</i> will keep DDS samples in its queue for ACK-disabled readers for a minimum keep duration (see <a href="#">47.5.3 Disabling Positive Acknowledgements on page 795</a>).</p> <p>When strict reliability is not required, setting this to TRUE reduces overhead network traffic.</p>
DDS_Boolean	disable_inline_keyhash	<p>Controls whether or not the key-hash is propagated on the wire with DDS samples.</p> <p>This field only applies to keyed writers.</p> <p><i>Connex</i> associates a key-hash (an internal 16-byte representation) with each key.</p> <p>When FALSE, the key-hash is sent on the wire with every data instance.</p> <p>When TRUE, the key-hash is not sent on the wire (so the readers must compute the value using the received data).</p> <p>If the <i>reader</i> is CPU bound, sending the key-hash on the wire may increase performance, because the reader does not have to get the key-hash from the data.</p> <div style="background-color: #ffffcc; padding: 5px; border: 1px solid #ccc;"> <p>If the writer is CPU bound, sending the key-hash on the wire may decrease performance, because it requires more bandwidth (16 more bytes per DDS sample).</p> </div> <div style="background-color: #ffffcc; padding: 5px; border: 1px solid #ccc;"> <p>Setting <code>disable_inline_keyhash</code> to TRUE is not compatible with using RTI Database Integration Service or RTI Recording Service.</p> </div>

Table 47.13 DDS\_DataWriterProtocolQosPolicy

Type	Field Name	Description
DDS_Boolean	serialize_key_with_dispose	<p>Controls whether or not the serialized key is propagated on the wire with dispose notifications.</p> <p>This field only applies to keyed writers.</p> <p>By default, this field is set to FALSE.</p> <p>RTI recommends setting this field to TRUE if there are <i>DataReaders</i> with <b>propagate_dispose_of_unregistered_instances</b> (in the <a href="#">48.1 DATA_READER_PROTOCOL QosPolicy (DDS Extension) on page 871</a>) also set to TRUE (which is done because you anticipate receiving a dispose meta-sample without previously having received a data sample for an instance).</p> <p>When setting <b>serialize_key_with_dispose</b> to FALSE, only a key hash is included in the dispose meta-sample sent by a <i>DataWriter</i> for a dispose action. If a dispose meta-sample only includes the key hash, then <i>DataReaders</i> must have previously received an actual data sample for the instance being disposed, in order for a <i>DataReader</i> to map a key hash/instance handle to actual key values.</p> <p>If an actual data sample was never received for an instance and <b>serialize_key_with_dispose</b> is set to FALSE, then the <i>DataReader</i> application will not be able to determine the value of the key that was disposed, since <b>FooDataReader::get_key_value()</b> will not be able to map an instance handle to actual key values.</p> <p>By setting <b>serialize_key_with_dispose</b> to TRUE, the values of the key members of a data type will be sent in the dispose meta-sample for a dispose action by the <i>DataWriter</i>. This allows the <i>DataReader</i> to map an instance handle to the values of the key members even when receiving a dispose meta-sample without previously having received a data sample for the instance.</p> <p>Important: When this field TRUE, batching will not be compatible with <i>RTI Data Distribution Service</i> 4.3e, 4.4b, or 4.4c—the <i>DataReaders</i> will receive incorrect data and/or encounter deserialization errors.</p>
DDS_Boolean	propagate_app_ack_with_no_response	<p>Controls whether or not a <i>DataWriter</i> receives <b>on_application_acknowledgment()</b> notifications with an empty or invalid response.</p> <p>When FALSE, <b>on_application_acknowledgment()</b> will not be invoked if the DDS sample being acknowledged has an empty or invalid response.</p>
DDS_RtpsReliableWriterProtocol_t	rtps_reliable_writer	<p>This structure includes the fields in <a href="#">Table 47.14 DDS_RtpsReliableWriterProtocol_t</a>.</p>
DDS_Sequence_t	initial_virtual_sequence_number	<p>Determines the initial virtual sequence number for this <i>DataWriter</i>.</p> <p>By default, the virtual sequence number of the first sample published by a <i>DataWriter</i> is 1 for <i>DataWriters</i> that do not use durable writer history. For durable writers, the default virtual sequence number is the last sequence number they published in a previous execution, plus one. So, when a non-durable <i>DataWriter</i> is restarted and must continue communicating with the same <i>DataReaders</i>, its samples start over with sequence number 1. Durable <i>DataWriters</i> start over where the last sequence number left off, plus one.</p> <p>This QoS setting allows overwriting the default initial virtual sequence number.</p> <p>Normally, this parameter is not expected to be modified; however, in some scenarios when continuing communication after restarting, applications may require the <i>DataWriter's</i> virtual sequence number to start at something other than the value described above. An example would be to enable non-durable <i>DataWriters</i> to start at the last sequence number published, plus one, similar to the durable <i>DataWriter</i>. This property enables you to make such a configuration, if desired.</p> <p>The virtual sequence number can be overwritten as well on a per sample basis by updating <b>DDS_WriteParams_t::identity</b> in <b>FooDataWriter_write_w_params</b>.</p>

Table 47.14 DDS\_RtpsReliableWriterProtocol\_t

Type	Field Name	Description
DDS_Long	low_watermark	Queue levels that control when to switch between the regular and fast heartbeat rates ( <a href="#">heartbeat_period</a> below and <a href="#">fast_heartbeat_period</a> below). See <a href="#">47.5.1 High and Low Watermarks</a> on page 793.
	high_watermark	
DDS_Duration_t	heartbeat_period	Rates at which to send heartbeats to <i>DataReaders</i> with unacknowledged DDS samples. See <a href="#">47.5.2 Normal, Fast, and Late-Joiner Heartbeat Periods</a> on page 794 and <a href="#">32.4.4.1 How Often Heartbeats are Resent (heartbeat_period)</a> on page 462.
	fast_heartbeat_period	
	late_joiner_heartbeat_period	
DDS_Duration_t	virtual_heartbeat_period	The rate at which a reliable <i>DataWriter</i> will send virtual heartbeats. Virtual heartbeat informs the reliable <i>DataReader</i> about the range of DDS samples currently present for each virtual GUID in the reliable writer's queue. See <a href="#">47.5.6 Virtual Heartbeats</a> on page 797.
DDS_Long	samples_per_virtual_heartbeat	The number of DDS samples that a reliable <i>DataWriter</i> must publish before sending a virtual heartbeat. See <a href="#">47.5.6 Virtual Heartbeats</a> on page 797.
DDS_Long	max_heartbeat_retries	<p>Maximum number of <i>periodic</i> heartbeats sent without receiving an ACK/NACK packet before marking a <i>DataReader</i> 'inactive.'</p> <p>When a <i>DataReader</i> has not acknowledged all the DDS samples the reliable <i>DataWriter</i> has sent to it, and <b>max_heartbeat_retries</b> number of periodic heartbeats have been sent without receiving any ACK/NACK packets in return, the <i>DataReader</i> will be marked as inactive (not alive) and be ignored until it resumes sending ACK/NACKs.</p> <p>Note that <i>piggyback</i> heartbeats do <i>not</i> count towards this value.</p> <p>See <a href="#">32.4.4.4 Controlling How Many Times Heartbeats are Resent (max_heartbeat_retries)</a> on page 467.</p>
DDS_Boolean	inactivate_nonprogressing_readers	<p>Allows the <i>DataWriter</i> to treat <i>DataReaders</i> that send successive non-progressing NACK packets as inactive.</p> <p>See <a href="#">32.4.4.5 Treating Non-Progressing Readers as Inactive Readers (inactivate_nonprogressing_readers)</a> on page 467.</p>
DDS_Long	heartbeats_per_max_samples	<p>When a <i>DataWriter</i> is configured with a fixed send window size (<b>min_send_window_size</b> is equal to effective <b>max_send_window_size</b>), a piggyback heartbeat is sent every [(effective <b>max_send_window_size</b>/heartbeats_per_max_samples)] number of samples written. (See <a href="#">47.5.4 Configuring the Send Window Size</a> on page 796.)</p> <p>Otherwise, the number of piggyback heartbeats sent is scaled according to the current size of the send window. For example, consider a <b>heartbeats_per_max_samples</b> of 50. If the current send window size is 100, a piggyback heartbeat will be sent every two samples. If the send window size grows to 150, a piggyback heartbeat will be sent every three samples, and so on. Additionally, when the send window size grows, a piggyback heartbeat is sent with the next sample. (If it weren't, the sending of that heartbeat could be delayed, since the heartbeat rate scales with the increasing window size.)</p> <p>The effective max send window is calculated as follows:</p> <p>Without batching, it is the minimum of <b>max_samples</b> in the <a href="#">47.22 RESOURCE_LIMITS QoSPolicy</a> on page 850 or <b>max_send_window_size</b>.</p> <p>With batching, it is the minimum of <b>max_batches</b> in the <a href="#">47.6 DATA_WRITER_RESOURCE_LIMITS QoSPolicy (DDS Extension)</a> on page 800 or <b>max_send_window_size</b>.</p> <p>If <b>heartbeats_per_max_samples</b> is set to zero, no piggyback heartbeat will be sent.</p> <p>If the current send window size is LENGTH_UNLIMITED, 100 million is assumed as the effective max send window.</p>
DDS_Boolean	disable_repair_piggyback_heartbeat	When samples are repaired, the <i>DataWriter</i> resends the number of bytes indicated in <b>max_bytes_per_nack_response</b> and a piggyback heartbeat with each message. You can configure the <i>DataWriter</i> to not send the piggyback heartbeat, by setting this field to TRUE, and instead rely on the <b>late_joiner_heartbeat_period</b> to control the throughput used to repair samples. This field is only mutable for the <i>DataWriter</i> QoS and not for the Discovery Config QoS of the <i>DomainParticipant</i> .

Table 47.14 DDS\_RtpsReliableWriterProtocol\_t

Type	Field Name	Description
DDS_Duration_t	min_nack_response_delay	<p>Minimum delay to respond to an ACK/NACK.</p> <p>When a reliable <i>DataWriter</i> receives an ACK/NACK from a <i>DataReader</i>, the <i>DataWriter</i> can choose to delay a while before it sends repair DDS samples or a heartbeat. The ACK/NACK will be sent at a random delay between this value and <b>max_nack_response_delay</b>.</p> <p>See <a href="#">32.4.4.6 Coping with Redundant Requests for Missing DDS Samples (max_nack_response_delay) on page 467</a>.</p>
DDS_Duration_t	max_nack_response_delay	<p>Maximum delay to respond to a ACK/NACK.</p> <p>This sets the value of maximum delay between receiving an ACK/NACK and sending repair DDS samples or a heartbeat. The ACK/NACK will be sent at a random delay between <b>min_nack_response_delay</b> and this value.</p> <p>A longer wait can help prevent storms of repair packets if many <i>DataReaders</i> send NACKs at the same time. However, it delays the repair, and hence increases the latency of the communication.</p> <p>See <a href="#">32.4.4.6 Coping with Redundant Requests for Missing DDS Samples (max_nack_response_delay) on page 467</a>.</p>
DDS_Duration_t	nack_suppression_duration	<p>How long consecutive NACKs are suppressed.</p> <p>When a reliable <i>DataWriter</i> receives consecutive NACKs within a short duration, this may trigger the <i>DataWriter</i> to send redundant repair messages. This value sets the duration during which consecutive NACKs are ignored, thus preventing redundant repairs from being sent.</p>
DDS_Long	max_bytes_per_nack_response	<p>Maximum bytes in a repair package.</p> <p>When a reliable <i>DataWriter</i> resends DDS samples, the total package size is limited to this value. Note: The reliable <i>DataWriter</i> will always send at least one sample.</p> <p>See <a href="#">32.4.4.3 Controlling Packet Size for Resent DDS Samples (max_bytes_per_nack_response) on page 466</a>.</p>
DDS_Duration_t	disable_positive_acks_min_sample_keep_duration	<p>Minimum duration that a DDS sample will be kept in the <i>DataWriter's</i> queue for ACK-disabled <i>DataReaders</i>.</p> <p>See <a href="#">47.5.3 Disabling Positive Acknowledgements on page 795</a> and <a href="#">32.4.4.7 Disabling Positive Acknowledgements (disable_positive_acks_min_sample_keep_duration) on page 469</a>.</p>
	disable_positive_acks_max_sample_keep_duration	<p>Maximum duration that a DDS sample will be kept in the <i>DataWriter's</i> queue for ACK-disabled readers.</p>
DDS_Boolean	disable_positive_acks_enable_adaptive_sample_keep_duration	<p>Enables automatic dynamic adjustment of the 'keep duration' in response to network congestion.</p>
DDS_Long	disable_positive_acks_increase_sample_keep_duration_factor	<p>When the 'keep duration' is dynamically controlled, the lengthening of the 'keep duration' is controlled by this factor, which is expressed as a percentage.</p> <p>When the adaptive algorithm determines that the keep duration should be increased, this factor is multiplied with the current keep duration to get the new longer keep duration. For example, if the current keep duration is 20 milliseconds, using the default factor of 150% would result in a new keep duration of 30 milliseconds.</p>
	disable_positive_acks_decrease_sample_keep_duration_factor	<p>When the 'keep duration' is dynamically controlled, the shortening of the 'keep duration' is controlled by this factor, which is expressed as a percentage.</p> <p>When the adaptive algorithm determines that the keep duration should be decreased, this factor is multiplied with the current keep duration to get the new shorter keep duration. For example, if the current keep duration is 20 milliseconds, using the default factor of 95% would result in a new keep duration of 19 milliseconds.</p>

Table 47.14 DDS\_RtpsReliableWriterProtocol\_t

Type	Field Name	Description
DDS_Long	min_send_window_size	Minimum and maximum size for the window of outstanding DDS samples. See <a href="#">47.5.4 Configuring the Send Window Size on page 796</a> .
	max_send_window_size	
DDS_Long	send_window_decrease_factor	Scales the current send-window size down by this percentage to decrease the effective send-rate in response to received negative acknowledgement. See <a href="#">47.5.4 Configuring the Send Window Size on page 796</a> .
DDS_Boolean	enable_multicast_periodic_heartbeat	Controls whether or not periodic heartbeat messages are sent over multicast. When enabled, if a reader has a multicast destination, the writer will send its periodic HEARTBEAT messages to that destination. Otherwise, if not enabled or the reader does not have a multicast destination, the writer will send its periodic HEARTBEATS over unicast.
DDS_Long	multicast_resend_threshold	Sets the minimum number of requesting readers needed to trigger a multicast resend. See <a href="#">47.5.7 Resending Over Multicast on page 798</a> .
DDS_Long	send_window_increase_factor	Scales the current send-window size up by this percentage to increase the effective send-rate when a duration has passed without any received negative acknowledgements. See <a href="#">47.5.4 Configuring the Send Window Size on page 796</a>
DDS_Duration	send_window_update_period	Period in which <i>DataWriter</i> checks for received negative acknowledgements and conditionally increases the send-window size when none are received. See <a href="#">47.5.4 Configuring the Send Window Size on page 796</a>

## 47.5.1 High and Low Watermarks

When the number of unacknowledged DDS samples in the current send-window of a reliable *DataWriter* meets or exceeds [high\\_watermark on page 791](#), the [31.6.8 RELIABLE\\_WRITER\\_CACHE\\_CHANGED Status \(DDS Extension\) on page 406](#) will be changed appropriately, a listener callback will be triggered, and the *DataWriter* will start heartbeating its matched *DataReaders* at [fast\\_heartbeat\\_period on page 791](#)

When the number of DDS samples meets or falls below [low\\_watermark on page 791](#), the [31.6.8 RELIABLE\\_WRITER\\_CACHE\\_CHANGED Status \(DDS Extension\) on page 406](#) will be changed appropriately, a listener callback will be triggered, and the heartbeat rate will return to the "normal" rate ([heartbeat\\_period on page 791](#)).

Having both high and low watermarks (instead of one) helps prevent rapid flickering between the rates, which could happen if the number of DDS samples hovers near the cut-off point.

Increasing the high and low watermarks will make the *DataWriters* less aggressive about seeking acknowledgments for sent data, decreasing the size of traffic spikes but slowing performance.

Decreasing the watermarks will make the *DataWriters* more aggressive, increasing both network utilization and performance.

If batching is used, [high\\_watermark on page 791](#) and [low\\_watermark on page 791](#) refer to batches, not DDS samples.

When [min\\_send\\_window\\_size on the previous page](#) and [max\\_send\\_window\\_size on the previous page](#) are not equal, the low and high watermarks are scaled down linearly to stay within the current send-window size. The value provided by configuration corresponds to the high and low watermarks for the [max\\_send\\_window\\_size on the previous page](#).

## 47.5.2 Normal, Fast, and Late-Joiner Heartbeat Periods

The normal [heartbeat\\_period on page 791](#) is used until the number of DDS samples in the reliable *DataWriter*'s queue meets or exceeds [high\\_watermark on page 791](#); then [fast\\_heartbeat\\_period on page 791](#) is used. Once the number of DDS samples meets or drops below [low\\_watermark on page 791](#), the normal rate ([heartbeat\\_period on page 791](#)) is used again.

- [fast\\_heartbeat\\_period on page 791](#) must be  $\leq$  [heartbeat\\_period on page 791](#)

Increasing [fast\\_heartbeat\\_period on page 791](#) increases the speed of discovery, but results in a larger surge of traffic when the *DataWriter* is waiting for acknowledgments.

Decreasing [heartbeat\\_period on page 791](#) decreases the steady state traffic on the wire, but may increase latency by decreasing the speed of repairs for lost packets when the writer does not have very many outstanding unacknowledged DDS samples.

Having two periodic heartbeat rates, and switching between them based on watermarks:

- Ensures that all *DataReaders* receive all their data as quickly as possible (the sooner they receive a heartbeat, the sooner they can send a NACK, and the sooner the *DataWriter* can send repair DDS samples);
- Helps prevent the *DataWriter* from overflowing its resource limits (as its queue starts to fill, the *DataWriter* sends heartbeats faster, prompting the *DataReaders* to acknowledge sooner, allowing the *DataWriter* to purge these acknowledged DDS samples from its queue);
- Tunes the amount of network traffic. (Heartbeats and NACKs use up network bandwidth like any other traffic; decreasing the heartbeat rates, or increasing the threshold before the fast rate starts, can smooth network traffic—at the expense of discovery performance).

The [late\\_joiner\\_heartbeat\\_period on page 791](#) is used when a reliable *DataReader* joins after a reliable *DataWriter* (with non-volatile Durability) has begun publishing DDS samples. Once the late-joining *DataReader* has received all cached DDS samples, it will be serviced at the same rate as other reliable *DataReaders*.

- [late\\_joiner\\_heartbeat\\_period on page 791](#) must be  $\leq$  [heartbeat\\_period on page 791](#)

## 47.5.3 Disabling Positive Acknowledgements

When strict reliable communication is not required, you can configure *Connex* so that it does *not* send positive acknowledgements (ACKs). In this case, reliability is maintained solely based on negative acknowledgements (NACKs). The removal of ACK traffic may improve middleware performance. For example, when sending DDS samples over multicast, ACK-storms that previously may have hindered *DataWriters* and consumed overhead network bandwidth are now precluded.

By default, *DataWriters* and *DataReaders* are configured with positive ACKS enabled. To disable ACKs, either:

- Configure the *DataWriter* to disable positive ACKs for all matching *DataReaders* (by setting **disable\_positive\_acks** to TRUE in the [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 788](#)).
- Disable ACKs for individual *DataReaders* (by setting **disable\_positive\_acks** to TRUE in the [48.1 DATA\\_READER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 871](#)).

If ACKs are disabled, instead of the *DataWriter* holding a DDS sample in its send queue until all of its *DataReaders* have ACKed it, the *DataWriter* will hold a DDS sample for a configurable duration. This "keep-duration" starts when a DDS sample is written. When this time elapses, the DDS sample is logically considered as acknowledged by its ACK-disabled readers.

The length of the "keep-duration" can be static or dynamic, depending on how **rtps\_reliable\_writer.disable\_positive\_acks\_enable\_adaptive\_sample\_keep\_duration** is set.

- When the length is static, the "keep-duration" is set to the minimum (**rtps\_reliable\_writer.disable\_positive\_acks\_min\_sample\_keep\_duration**).
- When the length is dynamic, the "keep-duration" is dynamically adjusted between the minimum and maximum durations (**rtps\_reliable\_writer.disable\_positive\_acks\_min\_sample\_keep\_duration** and **rtps\_reliable\_writer.disable\_positive\_acks\_max\_sample\_keep\_duration**).

Dynamic adjustment maximizes throughput and reliability in response to current network conditions: when the network is congested, durations are increased to decrease the effective send rate and relieve the congestion; when the network is not congested, durations are decreased to increase the send rate and maximize throughput.

You should configure the minimum "keep-duration" to allow at least enough time for a possible NACK to be received and processed. When a *DataWriter* has both matching ACK-disabled and ACK-enabled *DataReaders*, it holds a DDS sample in its queue until all ACK-enabled *DataReaders* have ACKed it and the "keep-duration" has elapsed.

See also: [32.4.4.7 Disabling Positive Acknowledgements \(disable\\_positive\\_acks\\_min\\_sample\\_keep\\_duration\) on page 469](#).

## 47.5.4 Configuring the Send Window Size

When a reliable *DataWriter* writes a DDS sample, it keeps the DDS sample in its queue until it has received acknowledgements from all of its subscribing *DataReaders*. The number of these outstanding DDS samples is referred to as the *DataWriter's* "send window." Once the number of outstanding DDS samples has reached the send window size, subsequent writes will block until an outstanding DDS sample is acknowledged.

Configuration of the send window sets a minimum and maximum size, which may be unlimited. The send window size is initialized to the minimum size. The min and max send windows can be the same. When set differently, the send window will dynamically change in response to detected network congestion, as signaled by received negative acknowledgements. When NACKs are received, the *DataWriter* responds to the slowed reader by decreasing the send window by the **send\_window\_decrease\_factor** to throttle down its effective send rate. The send window will not be decreased to less than the **min\_send\_window\_size**. After a period (**send\_window\_update\_period**) during which no NACKs are received, indicating that the reader is catching up, the *DataWriter* will increase the send window size to increase the effective send rate by the percentage specified by **send\_window\_increase\_factor**. The send window will increase to no greater than the **max\_send\_window\_size**.

When both **min\_send\_window\_size** and **max\_send\_window\_size** are unlimited, either the resource limits **max\_samples** in [47.22 RESOURCE\\_LIMITS QoSPolicy on page 850](#) (for non-batching) or **max\_batches** in [47.6 DATA\\_WRITER\\_RESOURCE\\_LIMITS QoSPolicy \(DDS Extension\) on page 800](#) (for batching) serves as the effective **max\_send\_window\_size**.

When either **max\_samples** (for non-batching) or **max\_batches** (for batching) is less than **max\_send\_window\_size**, it serves as the effective **max\_send\_window\_size**. If it is also less than **min\_send\_window\_size**, then effectively both min and max send-window sizes are equal to **max\_samples** or **max\_batches**.

## 47.5.5 Propagating Serialized Keys with Disposed-Instance Notifications

This section describes the interaction between these two fields:

- **serialize\_key\_with\_dispose** in [47.5 DATA\\_WRITER\\_PROTOCOL QoSPolicy \(DDS Extension\) on page 788](#)
- **propagate\_dispose\_of\_unregistered\_instances** in [48.1 DATA\\_READER\\_PROTOCOL QoSPolicy \(DDS Extension\) on page 871](#)

RTI recommends setting **serialize\_key\_with\_dispose** to TRUE if there are *DataReaders* with **propagate\_dispose\_of\_unregistered\_instances** also set to TRUE. The following examples will help you understand how these fields work.

See also: [31.14.3 Disposing Instances on page 428](#).

### Example 1

As mentioned above, this combination of settings is not recommended:

1. *DataWriter's* **serialize\_key\_with\_dispose** = FALSE
2. *DataReader's* **propagate\_dispose\_of\_unregistered\_instances** = TRUE
3. *DataWriter* calls **dispose()** for an instance before writing any DDS samples
4. *DataReader* calls **take()** and receives a disposed-instance notification (without a key)
5. *DataReader* calls **get\_key\_value()**, which returns an error because there is no key associated with the disposed-instance notification

### Example 2

1. *DataWriter's* **serialize\_key\_with\_dispose** = TRUE
2. *DataReader's* **propagate\_dispose\_of\_unregistered\_instances** = FALSE
3. *DataWriter* calls **dispose()** for an instance before writing any DDS samples
4. *DataReader* calls **take()**, which does not return any DDS samples because none were written, and it does not receive any disposed-instance notifications because **propagate\_dispose\_of\_unregistered\_instances** = FALSE

### Example 3

1. *DataWriter's* **serialize\_key\_with\_dispose** = TRUE
2. *DataReader's* **propagate\_dispose\_of\_unregistered\_instances** = TRUE
3. *DataWriter* calls **dispose()** for an instance before writing any DDS samples
4. *DataReader* calls **take()** and receives the disposed-instance notification
5. *DataReader* calls **get\_key\_value()** and receives the key for the disposed-instance notification

**Note:** *Persistence Service DataReaders* ignore the serialized key propagated with dispose updates. *Persistence Service DataWriters* cannot propagate the serialized key with dispose, and therefore ignore the **serialize\_key\_with\_dispose** setting on the *DataWriter* QoS.

## 47.5.6 Virtual Heartbeats

Virtual heartbeats announce the availability of DDS samples with the Collaborative DataWriters feature described in [48.1 DATA\\_READER\\_PROTOCOL QoSPolicy \(DDS Extension\) on page 871](#), where multiple *DataWriters* publish DDS samples from a common logical data-source (identified by a virtual GUID).

When [46.6 PRESENTATION QosPolicy on page 760](#) `access_scope` is set to `TOPIC` or `INSTANCE` on the *Publisher*, the virtual heartbeat contains information about the DDS samples contained in the *DataWriter* queue.

When presentation `access_scope` is set to `GROUP` on the *Publisher*, the virtual heartbeat contains information about the DDS samples in the queues of all *DataWriters* that belong to the *Publisher*.

## 47.5.7 Resending Over Multicast

Given *DataReaders* with multicast destinations, when a *DataReader* sends a NACK to request for DDS samples to be resent, the *DataWriter* can either resend them over unicast or multicast. Though resending over multicast would save bandwidth and processing for the *DataWriter*, the potential problem is that there could be *DataReaders* of the multicast group that did not request for any resends, yet they would have to process, and drop, the resent DDS samples.

Thus, to make each multicast resend more efficient, the `multicast_resend_threshold` is set as the minimum number of *DataReaders* of the same multicast group that the *DataWriter* must receive NACKs from within a single response-delay duration. This allows the *DataWriter* to coalesce near-simultaneous unicast resends into a multicast resend, and it allows a "vote" from *DataReaders* of a multicast group to exceed a threshold before resending over multicast.

The `multicast_resend_threshold` must be set to a positive value. Note that a threshold of 1 means that all resends will be sent over multicast. Also, note that a *DataWriter* with a zero NACK response-delay (i.e., both `min_nack_response_delay` and `max_nack_response_delay` are zero) will resend over multicast only if the threshold is 1.

## 47.5.8 Example

For information on how to use the fields in [Table 47.14 DDS\\_RtpsReliableWriterProtocol\\_t](#), see [32.4.4 Controlling Heartbeats and Retries with DataWriterProtocol QosPolicy on page 462](#).

The following describes a use case for when to change `push_on_write` to `DDS_BOOLEAN_FALSE`. Suppose you have a system in which the data packets being sent is very small. However, you want the data to be sent reliably, and the latency between the time that data is sent to the time that data is received is not an issue. However, the total network bandwidth between the *DataWriter* and *DataReader* applications is limited.

If the *DataWriter* sends a burst of data at a high rate, it is possible that it will overwhelm the limited bandwidth of the network. If you allocate enough space for the *DataWriter* to store the data burst being sent (see [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#)), then you can use the `push_on_write` parameter of the `DATA_WRITER_PROTOCOL` QosPolicy to delay sending the data until the reliable *DataReader* asks for it.

By setting `push_on_write` to `DDS_BOOLEAN_FALSE`, when `write()` is called on the *DataWriter*, no data is actually sent. Instead data is stored in the *DataWriter*'s send queue. Periodically, *Connex* will

be sending heartbeats informing the *DataReader* about the data that is available. So every heartbeat period, the *DataReader* will realize that the *DataWriter* has new data, and it will send an ACK/NACK, asking for them.

When *DataWriter* receives the ACK/NACK packet, it will put together a package of data, up to the size set by the parameter **max\_bytes\_per\_nack\_response**, to be sent to the *DataReader*. This method not only self-throttles the send rate, but also uses network bandwidth more efficiently by eliminating redundant packet headers when combining several small packets into one larger one. Please note that the *DataWriter* will always send at least one sample.

## 47.5.9 Properties

This QosPolicy cannot be modified after the *DataWriter* is created.

Since it is only for *DataWriters*, there are no compatibility restrictions for how it is set on the publishing and subscribing sides.

When setting the fields in this policy, the following rules apply. If any of these are false, *Connex* returns **DDS\_RETCODE\_INCONSISTENT\_POLICY**:

- **min\_nack\_response\_delay** <= **max\_nack\_response\_delay**
- **fast\_heartbeat\_period** <= **heartbeat\_period**
- **late\_joiner\_heartbeat\_period** <= **heartbeat\_period**
- **low\_watermark** < **high\_watermark**
- If batching is disabled:
  - **heartbeats\_per\_max\_samples** <= **writer\_qos.resource\_limits.max\_samples**
- If batching is enabled:
  - **heartbeats\_per\_max\_samples** <= **writer\_qos.resource\_limits.max\_batches**

## 47.5.10 Related QosPolicies

- [48.1 DATA\\_READER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 871](#)
- [47.12 HISTORY QosPolicy on page 818](#)
- [47.21 RELIABILITY QosPolicy on page 845](#)

## 47.5.11 Applicable DDS Entities

- [Chapter 31 DataWriters on page 389](#)

## 47.5.12 System Resource Considerations

A high `max_bytes_per_nack_response` may increase the instantaneous network bandwidth required to send a single burst of traffic for resending dropped packets.

## 47.6 DATA\_WRITER\_RESOURCE\_LIMITS QosPolicy (DDS Extension)

This QosPolicy defines various settings that configure how *DataWriters* allocate and use physical memory for internal resources.

It includes the members in [Table 47.15 DDS\\_DataWriterResourceLimitsQosPolicy](#). For defaults and valid ranges, please refer to the API Reference HTML documentation.

**Table 47.15 DDS\_DataWriterResourceLimitsQosPolicy**

Type	Field Name	Description
DDS_Long	initial_concurrent_blocking_threads	Initial number of threads that are allowed to concurrently block on the <code>write()</code> call on the same <i>DataWriter</i> .
DDS_Long	max_concurrent_blocking_threads	Maximum number of threads that are allowed to concurrently block on <code>write()</code> call on the same <i>DataWriter</i> .
DDS_Long	max_remote_reader_filters	Maximum number of remote <i>DataReaders</i> for which this <i>DataWriter</i> will perform content-based filtering.
DDS_Long	initial_batches	Initial number of batches that a <i>DataWriter</i> will manage if batching is enabled.
DDS_Long	max_batches	Maximum number of batches that a <i>DataWriter</i> will manage if batching is enabled. When batching is enabled, the maximum number of DDS samples that a <i>DataWriter</i> can store is limited by this value and <code>max_samples</code> in <a href="#">47.22 RESOURCE_LIMITS QosPolicy on page 850</a> .
DDS_DataWriterResourceLimitsInstanceReplacementKind	instance_replacement	Sets the kinds of instances allowed to be replaced when a <i>DataWriter</i> reaches <code>max_instances</code> in the <a href="#">47.22 RESOURCE_LIMITS QosPolicy on page 850</a> . (See <a href="#">47.6.1 Configuring DataWriter Instance Replacement on page 802</a> .)
DDS_Boolean	replace_empty_instances	Whether to replace empty instances during instance replacement. (See <a href="#">47.6.1 Configuring DataWriter Instance Replacement on page 802</a> .)
DDS_Boolean	autoregister_instances	Whether to automatically register instances written with non-NIL handle that are not yet registered, which will otherwise return an error. This can be especially useful if the instance has been replaced.
DDS_Long	initial_virtual_writers	Initial number of virtual writers supported by a <i>DataWriter</i> .

Table 47.15 DDS\_DataWriterResourceLimitsQosPolicy

Type	Field Name	Description
DDS_Long	max_virtual_writers	Maximum number of virtual writers supported by a <i>DataWriter</i> . Sets the maximum number of unique virtual writers supported by a <i>DataWriter</i> , where virtual writers are added when DDS samples are written with the virtual writer GUID. This field is especially relevant in the configuration of <i>Persistence Service DataWriters</i> , since they publish information on behalf of multiple virtual writers.
DDS_Long	max_remote_readers	The maximum number of remote readers supported by a <i>DataWriter</i> .
DDS_Long	max_app_ack_remote_readers	The maximum number of application-level acknowledging remote readers supported by a <i>DataWriter</i> .
DDS_Long	initial_active_topic_queries	Initial number of active topic queries a <i>DataWriter</i> will manage.
DDS_Long	max_active_topic_queries	Maximum number of active topic queries a <i>DataWriter</i> will manage. When topic queries are enabled, the maximum number of topic queries that a <i>DataWriter</i> can process at the same time is limited by this value.
DDS_AllocationSettings_t	writer_loaned_sample_allocation	Sets the allocation settings of the <i>DataWriter</i> -managed sample pool, when using Zero Copy transfer over shared memory or FlatData language binding. The number of samples loaned by a <i>DataWriter</i> via <i>FooDataWriter</i> 's <code>get_loan()</code> operation is limited by the <code>max_count</code> in <code>writer_loaned_sample_allocation</code> . See <a href="#">Chapter 34 Sending Large Data on page 497</a> .
DDS_Boolean	initialize_writer_loaned_sample	Determines whether or not to initialize members to default values in loaned samples returned by <i>FooDataWriter</i> 's <code>get_loan()</code> operation, when using Zero Copy transfer over shared memory or FlatData language binding. See <a href="#">Chapter 34 Sending Large Data on page 497</a> .

*DataWriters* must allocate internal structures to handle the simultaneous blocking of threads trying to call `write()` on the same *DataWriter*, for the storage used to batch small DDS samples, and for content-based filters specified by *DataReaders*.

Most of these internal structures start at an initial size and by default, will grow as needed by dynamically allocating additional memory. You may set fixed, maximum sizes for these internal structures if you want to bound the amount of memory that a *DataWriter* can use. By setting the initial size to the maximum size, you will prevent *Connex*t from dynamically allocating any memory after the creation of the *DataWriter*.

When setting the fields in this policy, the following rule applies. If this is false, *Connex*t returns **DDS\_RETCODE\_INCONSISTENT\_POLICY**:

- `max_concurrent_blocking_threads`  $\geq$  `initial_concurrent_blocking_threads`

The `initial_concurrent_blocking_threads` is used to allocate necessary initial system resources. If necessary, it will be increased automatically up to the `max_concurrent_blocking_threads` limit.

Every user thread calling `write()` on a *DataWriter* may use a semaphore that will block the thread when the *DataWriter*'s send queue is full. Because user code may set a timeout, each thread must use a different semaphore. See the `max_blocking_time` parameter of the [47.21 RELIABILITY QoS Policy on page 845](#). This QoS is offered so that the user application can control the dynamic allocation of system resources by *Connex*.

If you do not mind if *Connex* dynamically allocates semaphores when needed, then you can set the `max_concurrent_blocking_threads` parameter to some large value like `MAX_INT`. However, if you know exactly how many threads will be calling `write()` on the same *DataWriter*, and you do not want *Connex* to allocate any system resources or memory after initialization, then you should set:

```
max_concurrent_blocking_threads = initial_concurrent_blocking_threads = NUM
```

(where *NUM* is the number of threads that could possibly block concurrently).

Each *DataWriter* can perform content-based data filtering for up to `max_remote_reader_filters` number of *DataReaders*.

Values for `max_remote_reader_filters` may be.

- **0**: The *DataWriter* will not perform filtering for any *DataReader*, which means the *DataReader* will have to filter the data itself.
- **1 to (2<sup>31</sup>-2)**: The *DataWriter* will filter for up to the specified number of *DataReaders*. In addition, the *Datawriter* will store the result of the filtering per DDS sample per *DataReader*.
- **DDS\_LENGTH\_UNLIMITED** (default): The *DataWriter* will filter for up to (2<sup>31</sup>)-2 *DataReaders*. However, in this case, the *DataWriter* will not store the filtering result per DDS sample per *DataReader*. Thus, if a DDS sample is resent (such as due to a loss of reliable communication), the DDS sample will be filtered again.

For more information, see [18.3 ContentFilteredTopics on page 256](#).

## 47.6.1 Configuring DataWriter Instance Replacement

When the `max_instances` limit (in the [47.6 DATA\\_WRITER\\_RESOURCE\\_LIMITS QoS Policy \(DDS Extension\) on page 800](#)) is reached, a *DataWriter* will try to make space for a new instance by replacing an existing instance according to the instance replacement kind set in `instance_replacement` in the [47.6 DATA\\_WRITER\\_RESOURCE\\_LIMITS QoS Policy \(DDS Extension\) on page 800](#). For the sake of instance replacement, an instance is considered to be unregistered, disposed, or alive. The oldest instance of the specified kind, if such an instance exists, would be replaced with the new instance. Also, all DDS samples of a replaced instance must already have been acknowledged, such that removing the instance would not deprive any existing reader from receiving them.

Since an unregistered instance is one that a *DataWriter* will not update any further, unregistered instances are replaced before any other instance kinds. This applies for all `instance_replacement`

kinds; for example, the `ALIVE_THEN_DISPOSED` kind would first replace unregistered, then alive, and then disposed instances. The rest of the kinds specify one or two kinds (e.g. `DISPOSED` and `ALIVE_OR_DISPOSED`). For the single kind, if no unregistered instances are replaceable, and no instances of the specified kind are replaceable, then the instance replacement will fail. For the others specifying multiple kinds, it either specifies to look for one kind first and then another kind (e.g. `ALIVE_THEN_DISPOSED`), meaning if the first kind is found then that instance will be replaced, or it will replace either of the kinds specified (e.g. `ALIVE_OR_DISPOSED`), whichever is older as determined by the time of instance registering, writing, or disposing.

If an acknowledged instance of the specified kind is found, the *DataWriter* will reclaim its resources for the new instance. It will also invoke the *DataWriterListener*'s `on_instance_replaced()` callback (if installed) and notify the user with the handle of the replaced instance, which can then be used to retrieve the instance key from within the callback. If no replaceable instances are found, the new instance will fail to be registered; the *DataWriter* may block, if the instance registration was done in the context of a write, or it may return with an out-of-resources return code.

In addition, `replace_empty_instances` (in the [47.6 DATA\\_WRITER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 800](#)) configures whether instances with no DDS samples are eligible to be replaced. If this is set, then a *DataWriter* will first try to replace empty instances, even before replacing unregistered instances.

## 47.6.2 Example

If there are multiple threads that can write on the same *DataWriter*, and the `write()` operation may block (based on `reliability_qos.max_blocking_time` and `HISTORY` settings), you may want to set `initial_concurrent_blocking_threads` to the most likely number of threads that will block on the same *DataWriter* at the same time, and set `max_concurrent_blocking_threads` to the maximum number of threads that could potentially block in the worst case.

## 47.6.3 Properties

This *QosPolicy* cannot be modified after the *DataWriter* is created.

Since it is only for *DataWriters*, there are no compatibility restrictions for how it is set on the publishing and subscribing sides.

## 47.6.4 Related QosPolicies

- [47.2 BATCH QosPolicy \(DDS Extension\) on page 773](#)
- [47.21 RELIABILITY QosPolicy on page 845](#)
- [47.12 HISTORY QosPolicy on page 818](#)

## 47.6.5 Applicable DDS Entities

- [Chapter 31 DataWriters on page 389](#)

## 47.6.6 System Resource Considerations

Increasing the values in this QosPolicy will cause more memory usage and more system resource usage.

## 47.7 DEADLINE QosPolicy

On a *DataWriter*, this QosPolicy states the maximum period in which the application expects to call **write()** on the *DataWriter*, thus publishing a new DDS sample. The application may call **write()** faster than the rate set by this QosPolicy.

On a *DataReader*, this QosPolicy states the maximum period in which the application expects to receive new values for the *Topic*. The application may receive data faster than the rate set by this QosPolicy.

The DEADLINE QosPolicy has a single member, shown in [Table 47.16 DDS\\_DeadlineQosPolicy](#). For the default and valid range, please refer to the API Reference HTML documentation.

**Table 47.16 DDS\_DeadlineQosPolicy**

Type	Field Name	Description
DDS_Duration_t	period	For <i>DataWriters</i> : maximum time between writing a new value of an instance. For <i>DataReaders</i> : maximum time between receiving new values for an instance.

You can use this QosPolicy during system integration to ensure that applications have been coded to meet design specifications. You can also use it during run time to detect when systems are performing outside of design specifications. Receiving applications can take appropriate actions to prevent total system failure when data is not received in time. For topics on which data is not expected to be periodic, the deadline period should be set to an infinite value.

For keyed topics, the DEADLINE QoS applies on a per-instance basis. An application must call **write()** for each known instance of the *Topic* within the **period** specified by the DEADLINE on the *DataWriter* or receive a new value for each known instance within the **period** specified by the DEADLINE on the *DataReader*. For a *DataWriter*, the deadline period begins when the instance is first written or registered. For a *DataReader*, the deadline period begins when the first DDS sample is received.

*Connex* will modify the *OFFERED\_DEADLINE\_MISSED\_STATUS* and call the associated method in the **DataWriterListener** (see [31.6.5 OFFERED\\_DEADLINE\\_MISSED Status on page 404](#)) if the application fails to **write()** a value for an instance within the period set by the DEADLINE QosPolicy of the *DataWriter*.

Similarly, *Connex* will modify the `REQUESTED_DEADLINE_MISSED_STATUS` and call the associated method in the *DataReaderListener* (see [40.7.5 REQUESTED\\_DEADLINE\\_MISSED Status on page 635](#)) if the application fails to receive a value for an instance within the period set by the DEADLINE QoSPolicy of the *DataReader*.

For *DataReaders*, the DEADLINE QoSPolicy and the [48.4 TIME\\_BASED\\_FILTER QoSPolicy on page 888](#) may interact such that even though the *DataWriter* writes DDS samples fast enough to fulfill its commitment to its own DEADLINE QoSPolicy, the *DataReader* may see violations of its DEADLINE QoSPolicy. This happens because *Connex* will drop any packets received within the **minimum\_separation** set by the TIME\_BASED\_FILTER—packets that could satisfy the *DataReader*'s deadline.

To avoid triggering the *DataReader*'s deadline even though the matched *DataWriter* is meeting its own deadline, set your QoS parameters to meet the following relationship:

```
reader deadline period >= reader minimum_separation + writer deadline period
```

Although you can set the DEADLINE QoSPolicy on *Topics*, its value can only be used to initialize the DEADLINE QoSPolicies of either a *DataWriter* or *DataReader*. It does not directly affect the operation of *Connex*, see [18.1.3 Setting Topic QoS Policies on page 250](#).

## 47.7.1 Example

Suppose you have a time-critical piece of data that should be updated at least once every second. You can set the DEADLINE **period** to 1 second on both the *DataWriter* and *DataReader*. If there is no update within that time, the *DataWriter* will get an **on\_offered\_deadline\_missed** *Listener* callback, and the *DataReader* will get **on\_requested\_deadline\_missed**, so that both sides can handle the error situation properly.

Note that in practice, there will be latency and jitter in the time between when data is sent and when data is received. Thus even if the *DataWriter* is sending data at exactly 1 second intervals, the *DataReader* may not receive the data at exactly 1 second intervals. More likely, it will *DataReader* will receive the data at 1 second plus a small variable quantity of time. Thus you should accommodate this practical reality in choosing the DEADLINE **period** as well as the actual update period of the *DataWriter* or your application may receive false indications of failure.

The DEADLINE QoSPolicy also interacts with the OWNERSHIP QoSPolicy when OWNERSHIP is set to **EXCLUSIVE**. If a *DataReader* fails to receive data from the highest strength *DataWriter* within its requested DEADLINE, then the *DataReaders* can fail-over to lower strength *DataWriters*, see the [47.17 OWNERSHIP QoSPolicy on page 833](#).

## 47.7.2 Properties

This QoSPolicy can be changed at any time.

The deadlines on the two sides must be compatible.

*DataWriter*'s **DEADLINE period** <= the *DataReader*'s **DEADLINE period**.

That is, the *DataReader* cannot expect to receive DDS samples more often than the *DataWriter* commits to sending them.

If the *DataReader* and *DataWriter* have compatible deadlines, *Connex*t monitors this "contract" and informs the application of any violations. If the deadlines are incompatible, both sides are informed and communication does not occur. The **ON\_OFFERED\_INCOMPATIBLE\_QOS** and the **ON\_REQUESTED\_INCOMPATIBLE\_QOS** statuses will be modified and the corresponding *Listeners* called for the *DataWriter* and *DataReader* respectively.

### 47.7.3 Related QosPolicies

- [47.15 LIVELINESS QosPolicy on page 825](#)
- [47.17 OWNERSHIP QosPolicy on page 833](#)
- [48.4 TIME\\_BASED\\_FILTER QosPolicy on page 888](#)

### 47.7.4 Applicable DDS Entities

- [18.1 Topics on page 246](#)
- [Chapter 31 DataWriters on page 389](#)
- [Chapter 40 DataReaders on page 615](#)

### 47.7.5 System Resource Considerations

A *Connex*t-internal thread will wake up at least by the **DEADLINE period** to check to see if the deadline was missed. It may wake up faster if the last DDS sample that was published or sent was close to the last time that the deadline was checked. Therefore a short **period** will use more CPU to wake and execute the thread checking the deadline.

## 47.8 DESTINATION\_ORDER QosPolicy

When multiple *DataWriters* send data for the same topic, the order in which data from different *DataWriters* are received by the applications of different *DataReaders* may be different. Thus different *DataReaders* may not receive the same "last" value when *DataWriters* stop sending data.

This policy controls how each subscriber resolves the final value of a data instance that is written by multiple *DataWriters* (which may be associated with different *Publishers*) running on different nodes.

This QosPolicy can be used to create systems that have the property of "eventual consistency." Thus intermediate states across multiple applications may be inconsistent, but when *DataWriters* stop sending changes to the same topic, all applications will end up having the same state.

Each DDS sample includes two timestamps: a source timestamp and a reception timestamp. The source timestamp is recorded by the *DataWriter* application when the data was written. The reception timestamp is recorded by the *DataReader* application when the data was received.

This QoS includes the members in [Table 47.17 DDS\\_DestinationOrderQoSPolicy](#).

**Table 47.17 DDS\_DestinationOrderQoSPolicy**

Type	Field Name	Description
DDS_DestinationOrderQoSPolicyKind	kind	Can be either: DDS_BY_RECEPTION_TIMESTAMP_DESTINATIONORDER_QOS DDS_BY_SOURCE_TIMESTAMP_DESTINATIONORDER_QOS
DDS_DestinationOrderQoSPolicyScopeKind	scope	Can be either: DDS_INSTANCE_SCOPE_DESTINATIONORDER_QOS - Indicates that data is ordered on a per instance basis if used along with DDS_BY_SOURCE_TIMESTAMP_DESTINATIONORDER_QOS. The source timestamp of the current sample is compared to the source timestamp of the previously received sample for the same instance. The tolerance check is also applied per instance. DDS_TOPIC_SCOPE_DESTINATIONORDER_QOS - Indicates that data is ordered on a per topic basis if used along with DDS_BY_SOURCE_TIMESTAMP_DESTINATIONORDER_QOS. The source timestamp of the current sample is compared to the source timestamp of the previously received sample for the same topic. The tolerance check is also applied per topic.
DDS_Duration_t	source_timestamp_tolerance	Allowed tolerance between source timestamps of consecutive DDS samples. Only applies when <b>kind</b> (above) is DDS_BY_SOURCE_TIMESTAMP_DESTINATIONORDER_QOS. <ul style="list-style-type: none"> <li>For a <i>DataWriter</i>: The write operation will fail if the source timestamp of the sample is older than the timestamp of the previously written DDS sample by more than the <b>source_timestamp_tolerance</b>.</li> <li>For a <i>DataReader</i>: A <i>DataReader</i> will accept a sample only if the source timestamp is no farther in the future from the reception timestamp than the <b>source_timestamp_tolerance</b>.</li> </ul>

This QoS policy can be set for both *DataWriters* and *DataReaders*. See [47.8.1 Properties on page 809](#) for compatibility rules.

For a *DataReader*:

- DDS\_BY\_RECEPTION\_TIMESTAMP\_DESTINATIONORDER\_QOS

Assuming the OWNERSHIP\_STRENGTH allows it, the latest received value for the instance should be the one whose value is kept. Data will be delivered by a *DataReader* in the order in which it was received (which may lead to inconsistent final values).

- DDS\_BY\_SOURCE\_TIMESTAMP\_DESTINATIONORDER\_QOS

If scope is set to DDS\_INSTANCE\_SCOPE\_DESTINATIONORDER\_QOS (default), within each instance, the sample's source timestamp shall be used to determine the most recent information. *This is the only setting that*, in the case of concurrent same-strength *DataWriters* updating

the same instance, *ensures that all DataReaders end up with the same final value for the instance*. If a *DataReader* receives a sample for an instance with a source timestamp that is older than the last source timestamp received for the instance, the sample is dropped. You can keep track of the total number of dropped samples for this reason with the **old\_source\_timestamp\_dropped\_sample\_count** field in the [40.7.2 DATA\\_READER\\_CACHE\\_STATUS on page 627](#). The `SAMPLE_REJECTED` status or the `SAMPLE_LOST` status will not be updated.

If `scope` is set to `DDS_TOPIC_SCOPE_DESTINATIONORDER_QOS`, the ordering is enforced per topic across all instances.

In addition, a *DataReader* will accept a sample only if the source timestamp is no farther in the future from the reception timestamp than the **source\_timestamp\_tolerance**. Otherwise, the DDS sample is dropped. You can keep track of the total number of dropped samples for this reason with the **tolerance\_source\_timestamp\_dropped\_sample\_count** field in the [40.7.2 DATA\\_READER\\_CACHE\\_STATUS on page 627](#). The `SAMPLE_REJECTED` status or the `SAMPLE_LOST` status will not be updated.

For the *DataWriter*:

- `DDS_BY_RECEPTION_TIMESTAMP_DESTINATIONORDER_QOS`

The *DataWriter* will not enforce source timestamp ordering when writing samples using the **DataWriter::write\_w\_timestamp** or **DataWriter::write\_w\_params** API. The source timestamp of a new sample can be older than the source timestamp of the previous samples.

- `DDS_BY_SOURCE_TIMESTAMP_DESTINATIONORDER_QOS`

If `scope` is set to `DDS_INSTANCE_SCOPE_DESTINATIONORDER_QOS` (default), when writing a sample, the sample's timestamp must not be older than the timestamp of the previously written DDS sample for the same instance. If, however, the timestamp is older than the timestamp of the previously written DDS sample—but the difference is less than the **source\_timestamp\_tolerance**—the DDS sample will use the previously written DDS sample's timestamp as its timestamp. Otherwise, if the difference is greater than the tolerance, the write will fail with return code `DDS_RETCODE_BAD_PARAMETER`.

If `scope` is set to `DDS_TOPIC_SCOPE_DESTINATIONORDER_QOS`, a new sample timestamp must not be older than the timestamp of the previously written DDS sample, across all instances. (The ordering is enforced across all instances.)

Although you can set the `DESTINATION_ORDER` QosPolicy on *Topics*, its value can only be used to initialize the `DESTINATION_ORDER` QosPolicies of either a *DataWriter* or *DataReader*. It does not directly affect the operation of *Connex*, see [18.1.3 Setting Topic QosPolicies on page 250](#).

## 47.8.1 Properties

This QoSPolicy *cannot* be modified after the *Entity* is enabled.

This QoS must be set compatibly between the *DataWriter* and the *DataReader*. The compatible combinations are shown in [Table 47.18 Valid Reader/Writer Combinations of DestinationOrder](#).

**Table 47.18 Valid Reader/Writer Combinations of DestinationOrder**

Destination Order		DataReader requests:	
		BY_SOURCE	BY_RECEPTION
DataWriter offers:	BY_SOURCE	compatible	compatible
	BY_RECEPTION	incompatible	compatible

If this QoSPolicy is set incompatibly, the **ON\_OFFERED\_INCOMPATIBLE\_QOS** and **ON\_REQUESTED\_INCOMPATIBLE\_QOS** statuses will be modified and the corresponding *Listeners* called for the *DataWriter* and *DataReader* respectively.

## 47.8.2 Related QoS Policies

- [47.17 OWNERSHIP QoS Policy on page 833](#)
- [47.12 HISTORY QoS Policy on page 818](#)

## 47.8.3 Applicable DDS Entities

- [18.1 Topics on page 246](#)
- [Chapter 31 DataWriters on page 389](#)
- [Chapter 40 DataReaders on page 615](#)

## 47.8.4 System Resource Considerations

The use of this policy does not significantly impact the use of resources.

## 47.9 DURABILITY QoS Policy

Because the publish-subscribe paradigm is connectionless, applications can create publications and subscriptions in any way they choose. As soon as a matching pair of *DataWriters* and *DataReaders* exist, the data published by the *DataWriter* will be delivered to the *DataReader*. However, a *DataWriter* may publish data before a *DataReader* has been created. For example, before you subscribe to a magazine, there have been past issues that were published.

The DURABILITY QoS Policy controls whether or not, and how, published DDS samples are stored by the *DataWriter* application for *DataReaders* that are found after the DDS samples were initially written. *DataReaders* use this QoS to request DDS samples that were published before the *DataReaders* were created. The analogy is for a new subscriber to a magazine to ask for issues that were published in the past. These are known as ‘historical’ DDS data samples. (Reliable *DataReaders* may wait for these historical DDS samples, see [40.5 Checking DataReader Status and StatusConditions on page 624](#).)

This QoS Policy can be used to help ensure that *DataReaders* get all data that was sent by *DataWriters*, regardless of when it was sent. This QoS Policy can increase system tolerance to failure conditions.

The [47.12 HISTORY QoS Policy on page 818](#) controls how many samples the *DataWriter* stores for repair to currently matched *DataReaders*. The DURABILITY QoS Policy controls how many samples the *DataWriter* stores for sending to late-joining *DataReaders* (*DataReaders* that are found after the samples were initially written). See [Figure 47.1: History Depth and Durability Depth on page 822](#).

See also [Mechanisms for Achieving Information Durability and Persistence \(Chapter 21 on page 288\)](#).

The possible settings for this QoS are:

- **DDS\_VOLATILE\_DURABILITY\_QOS**

*Connex* is not required to send and will not deliver any DDS data samples to *DataReaders* that are discovered after the DDS samples were initially published.

- **DDS\_TRANSIENT\_LOCAL\_DURABILITY\_QOS**

*Connex* will store and send previously published DDS samples for delivery to newly discovered *DataReaders* as long as the *DataWriter* still exists. For this setting to be effective, you must also set the [47.21 RELIABILITY QoS Policy on page 845](#) kind to Reliable (not Best Effort). Which particular DDS samples are kept depends on other QoS settings such as [47.12 HISTORY QoS Policy on page 818](#) and [47.22 RESOURCE\\_LIMITS QoS Policy on page 850](#).

- **DDS\_TRANSIENT\_DURABILITY\_QOS**

*Connex* will store previously published DDS samples in memory using *Persistence Service*, which will send the stored data to newly discovered *DataReaders*. Which particular DDS samples are kept and sent by *Persistence Service* depends on the [47.12 HISTORY QoS Policy on page 818](#) and [47.22 RESOURCE\\_LIMITS QoS Policy on page 850](#) of the *Persistence Service DataWriters*. These QoS Policies can be configured in the *Persistence Service* configuration file or through the [47.10 DURABILITY\\_SERVICE QoS Policy on page 814](#) of the *DataWriters* configured with DDS\_TRANSIENT\_DURABILITY\_QOS.

- **DDS\_PERSISTENT\_DURABILITY\_QOS**

*Connex* will store previously published DDS samples in permanent storage, like a disk, using *Persistence Service*, which will send the stored data to newly discovered *DataReaders*. Which particular DDS samples are kept and sent by *Persistence Service* depends on the [47.12 HISTORY QosPolicy on page 818](#) and [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#) in the *Persistence Service DataWriters*. These QosPolicies can be configured in the *Persistence Service* configuration file or through the [47.10 DURABILITY SERVICE QosPolicy on page 814](#) of the *DataWriters* configured with `DDS_PERSISTENT_DURABILITY_QOS`.

This QosPolicy includes the members in [Table 47.19 DDS\\_DurabilityQosPolicy](#). For default settings, please refer to the API Reference HTML documentation.

Table 47.19 DDS\_DurabilityQosPolicy

Type	Field Name	Description
DDS_DurabilityQosPolicyKind	kind	<p><b>DDS_VOLATILE_DURABILITY_QOS:</b> Do not save or deliver historical DDS samples.</p> <p><b>DDS_TRANSIENT_LOCAL_DURABILITY_QOS:</b> Save and deliver historical DDS samples if the <i>DataWriter</i> still exists.</p> <p><b>DDS_TRANSIENT_DURABILITY_QOS:</b> Save and deliver historical DDS samples using <i>Persistence Service</i> to store samples in volatile memory.</p> <p><b>DDS_PERSISTENCE_DURABILITY_QOS:</b> Save and deliver historical DDS samples using <i>Persistence Service</i> to store samples in non-volatile memory.</p>
DDS_Long	writer_depth	<p>How many DDS samples are stored per instance by the <i>DataWriter</i> application for sending to late-joining <i>DataReaders</i> (<i>DataReaders</i> that are found after the DDS samples were initially written).</p> <p>The default value, AUTO, makes this parameter equal to the following:</p> <ul style="list-style-type: none"> <li>History <b>depth</b> in the <a href="#">47.12 HISTORY QosPolicy on page 818</a> if the History <b>kind</b> is KEEP_LAST.</li> <li><b>max_samples_per_instance</b> in the <a href="#">47.22 RESOURCE_LIMITS QosPolicy on page 850</a> if the History <b>kind</b> is KEEP_ALL.</li> </ul> <p>The <b>writer_depth</b> must be &lt;= to the History <b>depth</b> in the HISTORY QosPolicy if the History <b>kind</b> is KEEP_LAST.</p> <p><b>writer_depth</b> applies only to non-volatile <i>DataWriters</i> (those for which the <b>kind</b> is DDS_TRANSIENT_LOCAL_DURABILITY_QOS, DDS_TRANSIENT_DURABILITY_QOS, or DDS_PERSISTENCE_DURABILITY_QOS).</p> <p><b>writer_depth</b> set on the <i>DataReader</i> side will be ignored.</p>
DDS_Boolean	direct_communication	<p>Whether or not a TRANSIENT or PERSISTENT <i>DataReader</i> should receive DDS samples directly from a TRANSIENT or PERSISTENT <i>DataWriter</i>.</p> <p>When TRUE, a TRANSIENT or PERSISTENT <i>DataReader</i> will receive DDS samples directly from the original <i>DataWriter</i>. The <i>DataReader</i> may also receive DDS samples from <i>Persistence Service</i>, but the duplicates will be filtered by the middleware.</p> <p>When FALSE, a TRANSIENT or PERSISTENT <i>DataReader</i> will receive DDS samples only from the <i>DataWriter</i> created by <i>Persistence Service</i>. This 'relay communication' pattern provides a way to guarantee eventual consistency.</p> <p>See <a href="#">21.5.1 RTI Persistence Service on page 305</a>.</p> <p>This field only applies to <i>DataReaders</i>.</p>

Information durability can be combined with required subscriptions in order to guarantee that DDS samples are delivered to a set of required subscriptions. For additional details on required subscriptions see [31.13 Required Subscriptions on page 424](#) and [47.1 AVAILABILITY QosPolicy \(DDS Extension\) on page 769](#).

A *DataWriter* will keep at most **History.depth** samples per instance until they are fully acknowledged. Samples outside of the **Durability.writer\_depth** for an instance will be removed once they are fully acknowledged. Only the most recent **Durability.writer\_depth** samples per instance will be kept by the *DataWriter* for delivery to late-joining non-volatile *DataReaders*.

When **writer\_depth** is used in combination with batching, it acts as a minimum number of samples that will be kept per instance, rather than a maximum. Any batch that contains a sample that falls within the **writer\_depth** of the instance to which it belongs will be sent to late-joining *DataReaders*.

This means that batches may be sent that contain samples from other instances, or the same instance, that fall outside of the **writer\_depth** for the instance to which they belong. For example, if the **writer\_depth** is set to 1 and a batch with two samples for the same instance is written, then when a late-joining *DataReader* is discovered, the *DataWriter* will send the batch containing two samples for the same instance to the *DataReader*.

## 47.9.1 Example

Suppose you have a *DataWriter* that sends data sporadically and its DURABILITY **kind** is set to **VOLATILE**. If a new *DataReader* joins the system, it won't see any data until the next time that **write()** is called on the *DataWriter*. If you want the *DataReader* to receive any data that is valid, old or new, both sides should set their DURABILITY *kind* to **TRANSIENT\_LOCAL**. This will ensure that the *DataReader* gets some of the previous DDS samples immediately after it is enabled.

## 47.9.2 Properties

This QosPolicy cannot be modified after the Entity has been created.

The *DataWriter* and *DataReader* must use compatible settings for this QosPolicy. To be compatible, the *DataWriter* and *DataReader* must use one of the valid combinations shown in [Table 47.20 Valid Combinations of Durability 'kind'](#).

If this QosPolicy is found to be incompatible, the **ON\_OFFERED\_INCOMPATIBLE\_QOS** and **ON\_REQUESTED\_INCOMPATIBLE\_QOS** statuses will be modified and the corresponding *Listeners* called for the *DataWriter* and *DataReader* respectively.

**Table 47.20 Valid Combinations of Durability 'kind'**

		DataReader requests:			
		VOLATILE	TRANSIENT_LOCAL	TRANSIENT	PERSISTENT

- [47.21 RELIABILITY QosPolicy on page 845](#)

- [47.10 DURABILITY SERVICE QosPolicy](#) below
- [47.1 AVAILABILITY QosPolicy \(DDS Extension\)](#) on page 769

## 47.9.4 Applicable Entities

- [18.1 Topics](#) on page 246
- [Chapter 31 DataWriters](#) on page 389
- [Chapter 40 DataReaders](#) on page 615

## 47.9.5 System Resource Considerations

Using this policy with a setting other than **VOLATILE** will cause *Connex*t to use CPU and network bandwidth to send old DDS samples to matching, newly discovered *DataReaders*. The actual amount of resources depends on the total size of data that needs to be sent.

The maximum number of DDS samples that will be kept on the *DataWriter*'s queue for late-joiners and/or required subscriptions is determined by **max\_samples** in RESOURCE\_LIMITS Qos Policy.

### System Resource Considerations With Required Subscriptions

By default, when TRANSIENT\_LOCAL durability is used in combination with required subscriptions, a *DataWriter* configured with KEEP\_ALL in the [47.12 HISTORY QosPolicy on page 818](#) will keep the DDS samples in its cache until they are acknowledged by all the required subscriptions. (For additional details, see [31.13 Required Subscriptions on page 424](#).) After the DDS samples are acknowledged by the required subscriptions they will be marked as reclaimable, but they will not be purged from the *DataWriter*'s queue until the *DataWriter* needs these resources for new DDS samples. This may lead to a non efficient resource utilization, specially when **max\_samples** is high or even UNLIMITED.

The *DataWriter*'s behavior can be changed to purge DDS samples after they have been acknowledged by all the active/matching *DataReaders* and all the required subscriptions configured on the *DataWriter*. To do so, set the **dds.data\_writer.history.purge\_samples\_after\_acknowledgment** property to 1 (see [47.19 PROPERTY QosPolicy \(DDS Extension\) on page 837](#)).

See [31.13 Required Subscriptions on page 424](#).

## 47.10 DURABILITY SERVICE QosPolicy

This QosPolicy is only used if the [47.9 DURABILITY QosPolicy on page 809](#) is PERSISTENT or TRANSIENT *and* you are using *Persistence Service*. It is used to store and possibly forward the data sent by the *DataWriter* to *DataReaders* that are created after the data was initially sent.

This QosPolicy configures certain parameters of *Persistence Service* when it operates on the behalf of the *DataWriter*, such as how much data to store. Specifically, this QosPolicy configures the HISTORY

and `RESOURCE_LIMITS` used by the fictitious *DataReader* and *DataWriter* used by *Persistence Service*.

Note however, that by default, *Persistence Service* will ignore the values in the [47.10 DURABILITY SERVICE QosPolicy on the previous page](#) and must be configured to use those values.

For more information, please see:

- [Mechanisms for Achieving Information Durability and Persistence \(Chapter 21 on page 288\)](#)
- [Introduction to RTI Persistence Service \(Chapter 73 on page 1206\)](#)
- [Configuring Persistence Service \(Chapter 74 on page 1207\)](#)

This QosPolicy includes the members in [Table 47.21 DDS\\_DurabilityServiceQosPolicy](#). For default values, please refer to the API Reference HTML documentation.

**Table 47.21 DDS\_DurabilityServiceQosPolicy**

Type	Field Name	Description
DDS_Duration_t	service_cleanup_delay	How long to keep all information regarding an instance. Can be: Zero (default): Purge disposed instances from Persistence Service immediately. However, this will only happen if use_durability_service = 1. INFINITE: Do not purge disposed instances.
DDS_HistoryQosPolicyKind	history_kind	Setting to use for the <a href="#">47.12 HISTORY QosPolicy on page 818</a> <b>kind</b> when recouping durable data.
DDS_Long	history_depth	Setting to use for the <a href="#">47.9 DURABILITY QosPolicy on page 809</a> <b>writer_depth</b> when recouping durable data. If the <a href="#">47.12 HISTORY QosPolicy on page 818</a> <b>depth</b> is set to a value lower than this value, then the HISTORY <b>depth</b> will be set equal to the value of this field.
DDS_Long	max_samples max_instances max_samples_per_instance	Settings to use for the <a href="#">47.22 RESOURCE_LIMITS QosPolicy on page 850</a> when feeding data to a late joiner.

The **service\_cleanup\_delay** in this QosPolicy controls when *Persistence Service* may remove all information regarding a data-instances. Information on a data-instance is maintained until all of the following conditions are met:

1. The instance has been explicitly disposed (**instance\_state** = NOT\_ALIVE\_DISPOSED).

2. All samples for the disposed instance have been acknowledged, including the dispose sample itself.
3. A time interval longer than DurabilityService QosPolicy's **service\_cleanup\_delay** has elapsed since the time that *Connex* detected that the previous two conditions were met. (Note: Only values of zero or INFINITE are currently supported for **service\_cleanup\_delay**.)

The **service\_cleanup\_delay** field is useful in the situation where your application disposes an instance and it crashes before it has a chance to complete additional tasks related to the disposition. Upon restart, your application may ask for initial data to regain its state and the delay introduced by **service\_cleanup\_delay** will allow your restarted application to receive the information about the disposed instance and complete any interrupted tasks.

Although you can set the DURABILITY\_SERVICE QosPolicy on a *Topic*, this is only useful as a means to initialize the DURABILITY\_SERVICE QosPolicy of a *DataWriter*. A *Topic*'s DURABILITY\_SERVICE setting does not directly affect the operation of *Connex*, see [18.1.3 Setting Topic QosPolicies on page 250](#).

## 47.10.1 Properties

This QosPolicy cannot be modified after the Entity has been enabled.

It does not apply to *DataReaders*, so there is no requirement for setting it compatibly on the sending and receiving sides.

## 47.10.2 Related QosPolicies

- [47.9 DURABILITY QosPolicy on page 809](#)
- [47.12 HISTORY QosPolicy on page 818](#)
- [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#)

## 47.10.3 Applicable Entities

- [18.1 Topics on page 246](#)
- [Chapter 31 DataWriters on page 389](#)

## 47.10.4 System Resource Considerations

Since this QosPolicy configures the HISTORY and RESOURCE\_LIMITS used by the fictitious *DataReader* and *DataWriter* used by *Persistence Service*, it does have some impact on resource usage.

## 47.11 ENTITY\_NAME QoS Policy (DDS Extension)

The ENTITY\_NAME QoS Policy assigns a name and role name to a *DomainParticipant*, *Publisher*, *Subscriber*, *DataReader*, or *DataWriter*.

How the **name** is used is strictly application-dependent.

It is useful to attach names that are meaningful to the user. These names (except for *Publishers* and *Subscribers*) are propagated during discovery so that applications can use these names to identify, in a user-context, the entities that it discovers. Also, *RTI Connex* tools will print the names of discovered entities (except for *Publishers* and *Subscribers*).

The **role\_name** identifies the role of the entity. It is used by the Collaborative DataWriter feature (see [47.1.1 Availability QoS Policy and Collaborative DataWriters on page 770](#)). With Durable Subscriptions, **role\_name** is used to specify to which Durable Subscription the *DataReader* belongs. (see [47.1.2 Availability QoS Policy and Required Subscriptions on page 771](#)).

This QoS Policy contains the members listed in [Table 47.22 DDS\\_EntityNameQoS Policy](#).

**Table 47.22 DDS\_EntityNameQoS Policy**

Type	Field Name	Description
char *	name	A null-terminated string up to 255 characters in length. To set this in XML, see <a href="#">50.4.8 Entity Names on page 939</a> .
char *	role_name	A null-terminated string up to 255 characters in length. To set this in XML, see <a href="#">50.4.8 Entity Names on page 939</a> . For Collaborative DataWriters, this name is used to specify to which endpoint group the <i>DataWriter</i> belongs. See <a href="#">47.1.1 Availability QoS Policy and Collaborative DataWriters on page 770</a> . For Required and Durable Subscriptions this name is used to specify to which Subscription the <i>DataReader</i> belongs. See <a href="#">31.13 Required Subscriptions on page 424</a> .

These names will appear in the built-in topic for the entity (see the tables in [28.2 Built-in DataReaders on page 360](#)).

Prior to **get\_qos()**, if the **name** and/or **role\_name** field in this QoS Policy is not null, *Connex* assumes the memory to be valid and big enough and may write to it. If that is not desired, set **name** and/or **role\_name** to NULL before calling **get\_qos()** and *Connex* will allocate adequate memory for name.

When you call the destructor of entity's QoS structure (*DomainParticipantQos*, *DataReaderQos*, or *DataWriterQos*) (in C++) or **<entity>Qos\_finalize()** (in C), *Connex* will attempt to free the memory used for **name** and **role\_name** if it is not NULL. If this behavior is not desired, set **name** and/or **role\_name** to NULL before you call the destructor of entity's QoS structure or **DomainParticipantQos\_finalize()**.

## 47.11.1 Properties

This QosPolicy cannot be modified after the entity is enabled.

## 47.11.2 Related QosPolicies

- None

## 47.11.3 Applicable Entities

- [16.3 DomainParticipants on page 81](#)
- [Chapter 30 Publishers on page 373](#)
- [Chapter 39 Subscribers on page 597](#)
- [Chapter 40 DataReaders on page 615](#)
- [Chapter 31 DataWriters on page 389](#)

## 47.11.4 System Resource Considerations

If the value of **name** in this QosPolicy is not NULL, some memory will be consumed in storing the information in the database, but should not significantly impact the use of resource.

## 47.12 HISTORY QosPolicy

This QosPolicy configures the number of DDS samples that *Connex*t will store locally for *DataWriters* and *DataReaders*. For reliable *DataWriters*, the HISTORY QosPolicy configures the reliability window, or the number of samples that are kept until all matching *DataReaders* have fully-acknowledged the samples. For keyed *Topics*, this QosPolicy applies on a per instance basis, so that *Connex*t will attempt to store the configured value of DDS samples for every instance (see [Chapter 8 DDS Samples, Instances, and Keys on page 17](#) for a discussion of keys and instances).

This QoS policy includes the members seen in [Table 47.23 DDS\\_HistoryQosPolicy](#). For defaults and valid ranges, please refer to the API Reference HTML documentation.

Table 47.23 DDS\_HistoryQosPolicy

Type	Field Name	Description
DDS_HistoryQos-PolicyKind	kind	<p>DDS_KEEP_LAST_HISTORY_QOS: keep the last <i>depth</i> number of DDS samples per instance.</p> <p>DDS_KEEP_ALL_HISTORY_QOS: keep all DDS samples. <i>Connex</i> will store up to the value of the <b>max_samples_per_instance</b> parameter in the <a href="#">47.22 RESOURCE_LIMITS QosPolicy on page 850</a>.</p> <p>For <i>DataWriters</i>, the samples are kept only until either they are fully acknowledged by all matching <i>DataReaders</i> or they are replaced. See <a href="#">31.8.2 write() behavior with KEEP_LAST and KEEP_ALL on page 413</a> for more information about when a sample may be replaced in the <i>DataWriter</i> queue.</p>
DDS_Long	depth	<p>If <i>kind</i> = DDS_KEEP_LAST_HISTORY_QOS, this is how many DDS samples to keep per instance. <b>depth</b> must be <math>\leq</math> <b>max_samples_per_instance</b> in the <a href="#">47.22 RESOURCE_LIMITS QosPolicy on page 850</a>.</p> <p>if <i>kind</i> = DDS_KEEP_ALL_HISTORY_QOS, this value is ignored.</p>

The **kind** determines whether or not to save a configured number of DDS samples or *all* DDS samples. In either case, when using a Reliable [47.21 RELIABILITY QosPolicy on page 845](#), the samples are kept until they are fully acknowledged by all matching *DataReaders*. Once a sample is fully acknowledged, it is removed from the *DataWriter's* queue, unless it needs to be kept for durability purposes. (See [47.9 DURABILITY QosPolicy on page 809](#)). The HISTORY QoS Policy **kind** can be set to either of the following:

- **DDS\_KEEP\_LAST\_HISTORY\_QOS.** *Connex* attempts to keep the latest values of the data-instance and discard the oldest ones when the limit as set by the depth parameter is reached; new data will overwrite the oldest data in the queue. Thus the queue acts like a circular buffer of length **depth**. Invalid samples are samples representing the disposal or unregistration of an instance. There is only ever one invalid sample per-instance and that one sample can be in different states depending on whether the instance has been disposed, unregistered, or both. How invalid samples affect the history depth differs for *DataReaders* and *DataWriters*:
  - For a *DataWriter*: *Connex* attempts to keep the most recent **depth** DDS samples of each instance (identified by a unique key) managed by the *DataWriter*. Invalid samples count towards the depth and may replace other DDS samples currently in the *DataWriter* queue.
  - For a *DataReader*: *Connex* attempts to keep the most recent **depth** DDS samples received for each instance (identified by a unique key) until the application takes them via the *DataReader's* **take()** operation. See [41.3 Accessing DDS Data Samples with Read or Take on page 665](#) for a discussion of the difference between **read()** and **take()**. Invalid samples do not count towards the **depth** and will not replace other DDS samples currently in the *DataReader* queue.
- **DDS\_KEEP\_ALL\_HISTORY\_QOS.** *Connex* attempts to keep all of the DDS samples of a *Topic*.

- For a *DataWriter*: *Connex*t attempts to keep all DDS samples published by the *DataWriter*.
- For a *DataReader*: *Connex*t attempts to keep all DDS samples received by the *DataReader* for a *Topic* (both keyed and non-keyed) until the application takes them via the *DataReader*'s **take()** operation. See [41.3 Accessing DDS Data Samples with Read or Take on page 665](#) for a discussion of the difference between **read()** and **take()**.
- The value of the **depth** parameter is ignored.

The above descriptions say “attempts to keep” because the actual number of DDS samples kept is subject to the limitations imposed by the [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#). All of the DDS samples of all instances of a *Topic* share a single physical queue that is allocated for a *DataWriter* or *DataReader*. The size of this queue is configured by the RESOURCE\_LIMITS QosPolicy. If there are many different instances for a *Topic*, it is possible that the physical queue may run out of space before the number of DDS samples reaches the **depth** for all instances.

In the **KEEP\_ALL** case, *Connex*t can only keep as many DDS samples for a *Topic* (independent of instances) as the size of the allocated queue. *Connex*t may or may not allocate more memory when the queue is filled, depending on the settings in the RESOURCE\_LIMITS QoS Policy of the *DataWriter* or *DataReader*.

This QosPolicy interacts with the [47.21 RELIABILITY QosPolicy on page 845](#) by controlling whether or not *Connex*t guarantees that ALL of the data sent is received or if only the last N data values sent are guaranteed to be received (a reduced level of reliability using the KEEP\_LAST setting). However, the physical sizes of the send and receive queues are *not* controlled by the History QosPolicy. The memory allocation for the queues is controlled by the [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#).

What happens when the physical queue is filled depends both on the setting for the HISTORY QosPolicy as well as the RELIABILITY QosPolicy.

- **DDS\_KEEP\_LAST\_HISTORY\_QOS**

- If RELIABILITY is **BEST\_EFFORT**: When the number of DDS samples for an instance in the queue reaches the value of **depth**, a new DDS sample for the instance will replace the oldest DDS sample for the instance in the queue.
- If RELIABILITY is **RELIABLE**: When the number of DDS samples for an instance in the queue reaches the value of **depth**, a new DDS sample for the instance will replace the oldest DDS sample for the instance in the queue—even if the DDS sample being overwritten has not been fully acknowledged as being received by all reliable *DataReaders*. This implies that the discarded DDS sample may be lost (with the reason LOST\_BY\_WRITER) by some reliable *DataReaders*. Thus, when using the **KEEP\_LAST** setting, strict reliability is not guaranteed. See [Reliability Models for Sending Data \(Chapter 32 on page 446\)](#) for a complete discussion on *Connex*t’s reliable protocol.

- **DDS\_KEEP\_ALL\_HISTORY\_QOS**

- If RELIABILITY is **BEST\_EFFORT**: For a *DataWriter*, if the number of DDS samples for an instance in the queue reaches the value of the [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#)'s **max\_samples\_per\_instance** field, a new DDS sample for the instance will replace the oldest DDS sample for the instance in the queue (regardless of instance). For a *DataReader*, a new DDS sample received by the *DataReader* when this resource limit is exceeded will be lost with the reason **DDS\_LOST\_BY\_SAMPLES\_PER\_INSTANCE\_LIMIT**.
- If RELIABILITY is **RELIABLE**: When the number of DDS samples for an instance in the queue reaches the value of the [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#)'s **max\_samples\_per\_instance** field, then:
  - For a *DataWriter*: A new DDS sample for the instance will replace the oldest DDS sample for the instance in the sending queue—*only* if the DDS sample being overwritten has been fully acknowledged as being received by all reliable *DataReaders*. If the oldest DDS sample for the instance has not been fully acknowledged, the **write ()** operation trying to enter a new DDS sample for the instance into the sending queue will block (for the **max\_blocking\_time** specified in the RELIABLE QosPolicy).
  - For a *DataReader*: **max\_samples\_per\_instance** represents the maximum number of DDS samples of any one instance that are stored in the *DataReader* output queue—that is, the queue from which the application takes/reads samples. Therefore, when **max\_samples\_per\_instance** is hit, the *DataWriter* samples will be rejected. They will not be moved to the *DataReader* output queue. They will stay in the *DataWriter's* remote writer queue until there is space for them in the *DataReader* output queue (until the samples in the *DataReader* output queue are taken). On a reliable *DataReader*, there is one remote writer queue for each *DataWriter* that matches the *DataReader*. The remote writer queue size is configurable with the resource limit **reader\_qos.reader\_resource\_limit.max\_samples\_per\_remote\_writer** (see [48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 876](#)).

Although you can set the HISTORY QosPolicy on *Topics*, its value can only be used to initialize the HISTORY QosPolicies of either a *DataWriter* or *DataReader*. It does not directly affect the operation of *Connex*, see [18.1.3 Setting Topic QosPolicies on page 250](#).

## 47.12.1 Example

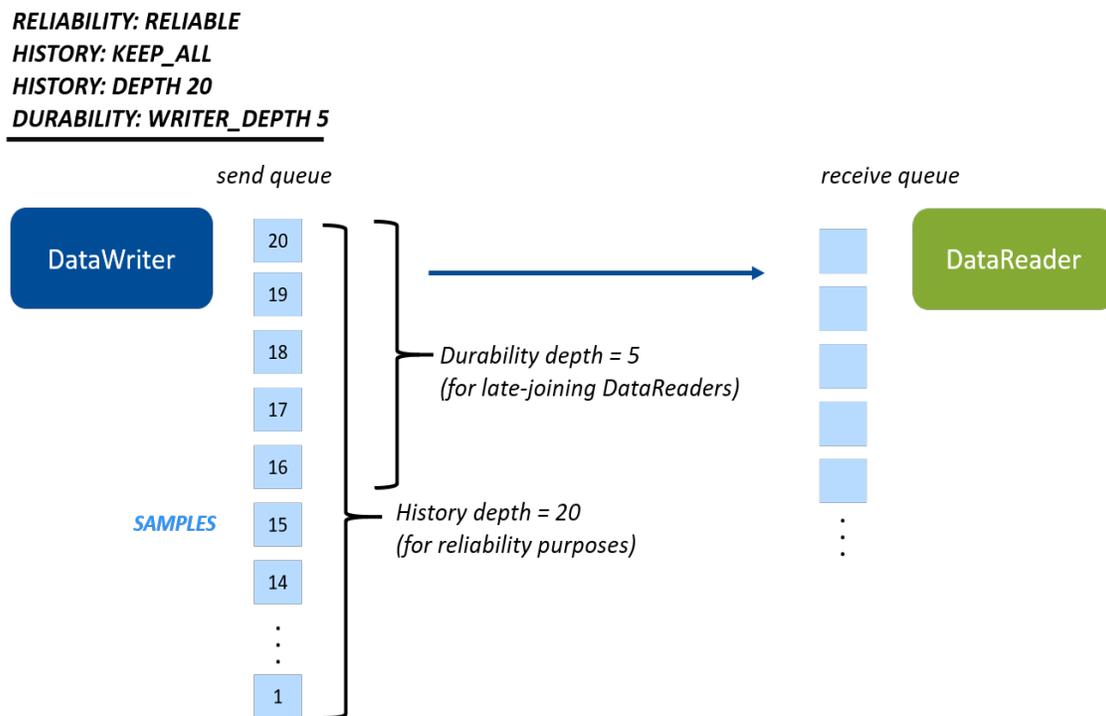

To achieve strict reliability, you must (1) set the *DataWriter's* and *DataReader's* HISTORY QosPolicy to **KEEP\_ALL**, and (2) set the *DataWriter's* and *DataReader's* RELIABILITY QosPolicy to **RELIABLE**.

See [Reliability Models for Sending Data \(Chapter 32 on page 446\)](#) for a complete discussion on *Connext's* reliable protocol.

See [32.4.3 Controlling Queue Depth with the History QosPolicy on page 461](#).

It is possible to configure the reliability window (the number of samples kept in the queue for reliability purposes) separately from the durability window (the number of samples kept in the *DataWriter* queue for late-joining *DataReaders*). This allows an application to achieve the level of reliability that is required and still only deliver a subset of data to late-joining *DataReaders* when using a non-VOLATILE [47.9 DURABILITY QosPolicy on page 809](#). [Figure 47.1: History Depth and Durability Depth below](#) shows the relationship between History **depth** and Durability **writer\_depth**.

**Figure 47.1: History Depth and Durability Depth**

*The History **depth** determines how many samples to keep for reliability purposes (for example, for redelivering to DataReaders that haven't acknowledged them yet). The [47.9 DURABILITY QosPolicy on page 809](#) **writer\_depth** determines what subset of those samples to deliver to late-joining DataReaders.*

## 47.12.2 Properties

This QosPolicy cannot be modified after the *Entity* has been enabled.

There is no requirement that the publishing and subscribing sides use compatible values.

### 47.12.3 Related QosPolicies

- [47.2 BATCH QosPolicy \(DDS Extension\) on page 773](#) Do not configure the *DataReader's* **depth** to be shallower than the *DataWriter's* maximum batch size (**batch\_max\_data\_size**). Because batches are acknowledged as a group, a *DataReader* that cannot process an entire batch will lose the remaining DDS samples in it.
- [47.21 RELIABILITY QosPolicy on page 845](#)
- [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#)

### 47.12.4 Applicable Entities

- [18.1 Topics on page 246](#)
- [Chapter 31 DataWriters on page 389](#)
- [Chapter 40 DataReaders on page 615](#)

### 47.12.5 System Resource Considerations

While this QosPolicy does not directly affect the system resources used by *Connex*, the [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#) that must be used in conjunction with the [47.12 HISTORY QosPolicy on page 818](#) will affect the amount of memory that *Connex* will allocate for a *DataWriter* or *DataReader*.

## 47.13 LATENCYBUDGET QoS Policy

This QosPolicy can be used by a DDS implementation to change how it processes and sends data that has low latency requirements. The DDS specification does not mandate whether or how this parameter is used. *Connex* uses it to prioritize the sending of asynchronously published data; see [46.1 ASYNCHRONOUS\\_PUBLISHER QosPolicy \(DDS Extension\) on page 740](#).

This QosPolicy also applies to *Topics*. The *Topic's* setting for the policy is ignored unless you explicitly make the *DataWriter* use it.

It contains the single member listed in [Table 47.24 DDS\\_LatencyBudgetQosPolicy](#).

**Table 47.24 DDS\_LatencyBudgetQosPolicy**

Type	Field Name	Description
DDS_Duration_t	duration	Provides a hint as to the maximum acceptable delay from the time the data is written to the time it is received by the subscribing applications.

### 47.13.1 Applicable Entities

- [18.1 Topics on page 246](#)
- [Chapter 31 DataWriters on page 389](#)
- [Chapter 40 DataReaders on page 615](#)

## 47.14 LIFESPAN QoS Policy

The purpose of this QoS is to avoid delivering stale data to the application by specifying how long the data written by a *DataWriter* is considered valid.

Each data sample written by a *DataWriter* has an associated expiration time beyond which the data should not be delivered to any application. Once the sample expires, the data will be removed from the *DataWriter* and *DataReader* caches.

The expiration time of each sample from the *DataWriter's* cache is computed by adding the duration specified by this QoS policy to the time when the sample is added to the *DataWriter's* cache. This timestamp is not necessarily equal to the sample's source timestamp that can be provided by the user using the *DataWriter's* `write_w_timestamp()` or `write_w_params()` APIs.

The expiration time of each sample from the *DataReader's* cache is computed by adding the duration to the reception timestamp.

The Lifespan QoSPolicy can be used to control how much data is stored by *Connex*. Even if it is configured to store "all" of the data sent or received for a topic (see the [47.12 HISTORY QoSPolicy on page 818](#)), the total amount of data it stores may be limited by the Lifespan QoSPolicy.

You may also use the Lifespan QoSPolicy to ensure that applications do not receive or act on data, commands or messages that are too old and have "expired."

It includes the single member listed in [Table 47.25 DDS\\_LifespanQoSPolicy](#). For the default and valid range, please refer to the API Reference HTML documentation.

**Table 47.25 DDS\_LifespanQosPolicy**

Type	Field Name	Description
DDS_Duration_t	duration	Maximum duration for the data's validity.

Although you can set the LIFESPAN QosPolicy on *Topics*, its value can only be used to initialize the LIFESPAN QosPolicies of *DataWriters*. The Topic's setting for this QosPolicy does not directly affect the operation of *Connex*, see [18.1.3 Setting Topic QosPolicies on page 250](#).

### 47.14.1 Properties

This QoS policy can be modified after the entity is enabled.

It does not apply to *DataReaders*, so there is no requirement that the publishing and subscribing sides use compatible values.

### 47.14.2 Related QoS Policies

- [47.2 BATCH QosPolicy \(DDS Extension\) on page 773](#) Be careful when configuring a *DataWriter* with a Lifespan **duration** shorter than the batch flush period (**batch\_flush\_delay**). If the batch does not fill up before the flush period elapses, the short **duration** by default will cause the DDS samples to be dropped without being sent. (You can, however, keep track of the number of these dropped samples via **writer\_removed\_batch\_sample\_dropped\_sample\_count** in the [40.7.2 DATA\\_READER\\_CACHE\\_STATUS on page 627](#). You can also choose not to drop these samples at all by setting the property **dds.data\_reader.accept\_writer\_removed\_batch\_samples** to TRUE (by default it is set to FALSE); you can set this property via the [47.19 PROPERTY QosPolicy \(DDS Extension\) on page 837](#).)
- [47.9 DURABILITY QosPolicy on page 809](#)

### 47.14.3 Applicable Entities

- [18.1 Topics on page 246](#)
- [Chapter 31 DataWriters on page 389](#)

### 47.14.4 System Resource Considerations

The use of this policy does not significantly impact the use of resources.

## 47.15 LIVELINESS QosPolicy

The LIVELINESS QosPolicy specifies how *Connex* determines whether a *DataWriter* is “alive.” A *DataWriter*'s liveliness is used in combination with the [47.17 OWNERSHIP QosPolicy on page 833](#) to maintain ownership of an instance (note that the [47.7 DEADLINE QosPolicy on page 804](#) is also used

to change ownership when a *DataWriter* is still alive). That is, for a *DataWriter* to own an instance, the *DataWriter* must still be alive as well as honoring its DEADLINE contract.

It includes the members in [Table 47.26 DDS\\_LivelinessQoSPolicy](#). For defaults and valid ranges, please refer to the API Reference HTML documentation.

**Table 47.26 DDS\_LivelinessQoSPolicy**

Type	Field Name	Description
DDS_LivelinessQoSPolicyKind	kind	<p>DDS_AUTOMATIC_LIVELINESS_QOS:  <i>Connex</i> will automatically assert liveliness for the <i>DataWriter</i> at least as often as the <b>lease_duration</b>.</p> <p>DDS_MANUAL_BY_PARTICIPANT_LIVELINESS_QOS:  The <i>DataWriter</i> is assumed to be alive if any Entity within the same <i>DomainParticipant</i> has asserted its liveliness.</p> <p>DDS_MANUAL_BY_TOPIC_LIVELINESS_QOS:  Your application must explicitly assert the liveliness of the <i>DataWriter</i> within the <b>lease_duration</b>.</p>
DDS_Duration_t	lease_duration	<p>The timeout by which liveliness must be asserted for the <i>DataWriter</i> or the <i>DataWriter</i> will be considered inactive or not alive.</p> <p>Additionally, for <i>DataReaders</i>, the <b>lease_duration</b> also specifies the maximum period at which <i>Connex</i> will check to see if the matching <i>DataWriter</i> is still alive.</p> <p><b>A <i>DataReader</i> will consider a <i>DataWriter</i> not alive if the <i>DataWriter</i> does not assert its liveliness within the <i>DataWriter</i>'s <b>lease_duration</b>, not the <i>DataReader</i>'s <b>lease_duration</b>.</b></p>
DDS_Long	assertions_per_lease_duration	<p>The number of assertions a <i>DataWriter</i> will send during a <b>lease_duration</b> period.</p> <p>This field only applies to <i>DataWriters</i> using DDS_AUTOMATIC_LIVELINESS_QOS kind and it is not considered during QoS compatibility checks.</p> <p>The default value is 3. A higher value will make the liveliness mechanism more robust against packet losses, but it will also increase the network traffic.</p>

Setting a *DataWriter*'s **kind** of LIVELINESS specifies the mechanism that will be used to assert liveliness for the *DataWriter*. The *DataWriter*'s **lease\_duration** then specifies the maximum period at which packets that indicate that the *DataWriter* is still alive are sent to matching *DataReaders*.

The various mechanisms are:

- **DDS\_AUTOMATIC\_LIVELINESS\_QOS:**

The *DomainParticipant* is responsible for automatically sending packets to indicate that the *DataWriter* is alive; this will be done at the rate determined by the **assertions\_per\_lease\_duration** and **lease\_duration** values. This setting is appropriate when the primary failure mode is that the publishing application itself dies. It does not cover the case in which the application is still alive but in an erroneous state—allowing the *DomainParticipant* to continue to assert liveliness for the *DataWriter* but preventing threads from calling **write()** on the *DataWriter*.

As long as the internal threads spawned by *Connex*t for a *DomainParticipant* are running, then the liveliness of the *DataWriter* will be asserted regardless of the state of the rest of the application.

This setting is certainly the most convenient, if the least accurate, method of asserting liveliness for a *DataWriter*.

- **DDS\_MANUAL\_BY\_PARTICIPANT\_LIVELINESS\_QOS:**

*Connex*t will assume that as long as the user application has asserted the liveliness of at least one *DataWriter* belonging to the same *DomainParticipant* or the liveliness of the *DomainParticipant* itself, then this *DataWriter* is also alive.

This setting allows the user code to control the assertion of liveliness for an entire group of *DataWriters* with a single operation on any of the *DataWriters* or their *DomainParticipant*. It's a good balance between control and convenience.

- **DDS\_MANUAL\_BY\_TOPIC\_LIVELINESS\_QOS:**

The *DataWriter* is considered alive only if the user application has explicitly called operations that assert the liveliness for that particular *DataWriter*.

This setting forces the user application to assert the liveliness for a *DataWriter* which gives the user application great control over when other applications can consider the *DataWriter* to be inactive, but at the cost of convenience.

With the *MANUAL\_BY\_[TOPIC,PARTICIPANT]* settings, user application code can assert the liveliness of *DataWriters* either explicitly by calling the **assert\_liveliness()** operation on the *DataWriter* (as well as the *DomainParticipant* for the *MANUAL\_BY\_PARTICIPANT* setting) or implicitly by calling **write()** on the *DataWriter*. If the application does not use either of the methods mentioned at least once every **lease\_duration**, then the subscribing application may assume that the *DataWriter* is no longer alive. Sending data *MANUAL\_BY\_TOPIC* will cause an assert message to be sent between the *DataWriter* and its matched *DataReaders*.

Publishing applications will monitor their *DataWriters* to make sure that they are honoring their LIVELINESS QosPolicy by asserting their liveliness at least at the period set by the **lease\_duration**. If *Connex*t finds that a *DataWriter* has failed to have its liveliness asserted by its **lease\_duration**, an internal thread will modify the *DataWriter*'s *LIVELINESS\_LOST\_STATUS* and trigger its **on\_liveliness\_lost()** *DataWriterListener* callback if a listener exists, see [15.8 Listeners on page 46](#).

Setting the *DataReader*'s **kind** of LIVELINESS requests a specific mechanism for the publishing application to maintain the liveliness of *DataWriters*. The subscribing application may want to know that the publishing application is explicitly asserting the liveliness of the matching *DataWriter* rather than inferring its liveliness through the liveliness of its *DomainParticipant* or its sibling *DataWriters*.

The *DataReader's* **lease\_duration** specifies the maximum period at which matching *DataWriters* must have their liveliness asserted. In addition, in the subscribing application *Connex*t uses an internal thread that wakes up at the period set by the *DataReader's* **lease\_duration** to see if the *DataWriter's* **lease\_duration** has been violated.

When a matching *DataWriter* is determined to be dead (inactive), *Connex*t will modify the **LIVELINESS\_CHANGED\_STATUS** of each matching *DataReader* and trigger that *DataReader's* **on\_liveliness\_changed()** *DataReaderListener* callback (if a listener exists).

Although you can set the LIVELINESS QosPolicy on *Topics*, its value can only be used to initialize the LIVELINESS QosPolicies of either a *DataWriter* or *DataReader*. It does not directly affect the operation of *Connex*t, see [18.1.3 Setting Topic QosPolicies on page 250](#).

For more information on Liveliness, see [25.1.2 Maintaining DataWriter Liveliness for kinds AUTOMATIC and MANUAL\\_BY\\_PARTICIPANT on page 338](#).

## 47.15.1 Timing Considerations for MANUAL\_BY\_PARTICIPANT

As mentioned in [47.15.6 System Resource Considerations on page 830](#), a per-*DomainParticipant* internal *Connex*t thread will wake up periodically to check the liveliness of the *DataWriters*. This same thread also checks if any of the MANUAL\_BY\_PARTICIPANT *DataWriters* within the *DomainParticipant* have asserted liveliness (by calling either the *DomainParticipant's* or the *DataWriter's* **assert\_liveliness()** API): if that is the case, that thread is responsible for sending a liveliness assertion message to any matched remote *DomainParticipants*.

The period of this thread is half of the time given by the minimum **lease\_duration** across all of the MANUAL\_BY\_PARTICIPANT *DataWriters* within the *DomainParticipant*. As a result, an application asserting MANUAL\_BY\_PARTICIPANT *DataWriters'* liveliness at a period equal to or higher than half of the minimum configured **lease\_duration** may run into local and/or remote *DataWriter* lost events.

For example, for a minimum **lease\_duration** across all *DataWriters* of 2 seconds and an application assertion period (the time between calls to **assert\_liveliness()**) of 1 second, the maximum time between two liveliness assertions will be given by:

```
"maximum time between two liveliness assertions" ~= ("minimum lease_duration across manual_by_participant datawriters" / 2) + "application assertion period"
```

which results in:

```
"maximum time between two liveliness assertions" ~= (2 / 2) second + 1 second = 2 seconds
```

This configuration results in potential (local and remote) liveliness losses since the **lease\_duration** is close to the maximum time between two liveliness assertions (in fact, the situation will be a bit worse since this configuration has not accounted for network delay/jittering delivering liveliness assertion messages).

Therefore, to avoid unexpected liveness losses, the user application should make sure that *DataWriters'* liveness is asserted at a period that is shorter than half of the minimum lease duration. For additional information and diagrams, see [25.1.2 Maintaining DataWriter Liveness for kinds AUTOMATIC and MANUAL\\_BY\\_PARTICIPANT](#) on page 338.

## 47.15.2 Example

You can use LIVENESS QosPolicy during system integration to ensure that applications have been coded to meet design specifications. You can also use it during run time to detect when systems are performing outside of design specifications. Receiving applications can take appropriate actions in response to disconnected *DataWriters*.

The LIVENESS QosPolicy can be used to manage fail-over when the [47.17 OWNERSHIP QosPolicy](#) on page 833 is set to **EXCLUSIVE**. This implies that the *DataReader* will only receive data from the highest strength *DataWriter* that is alive (active). When that *DataWriter's* liveness expires, then Connex will start delivering data from the next highest strength *DataWriter* that is still alive.

## 47.15.3 Properties

This QosPolicy cannot be modified after the Entity has been enabled.

The *DataWriter* and *DataReader* must use compatible settings for this QosPolicy. To be compatible, *both* of the following conditions must be true:

The *DataWriter* and *DataReader* must use one of the valid combinations shown in [Table 47.27 Valid Combinations of Liveness 'kind'](#).

*DataWriter's* **lease\_duration** <= *DataReader's* **lease\_duration**.

If this QosPolicy is found to be incompatible, the **ON\_OFFERED\_INCOMPATIBLE\_QOS** and **ON\_REQUESTED\_INCOMPATIBLE\_QOS** statuses will be modified and the corresponding *Listeners* called for the *DataWriter* and *DataReader* respectively.

Table 47.27 Valid Combinations of Liveliness 'kind'

		DataReader requests:		
		MANUAL_BY_TOPIC	MANUAL_BY_PARTICIPANT	AUTOMATIC
DataWriter of-fers:	MANUAL_BY_TOPIC	compatible	compatible	compatible
	MANUAL_BY_PARTICIPANT	incompatible	compatible	compatible
	AUTOMATIC	incompatible	incompatible	compatible

## 47.15.4 Related QosPolicies

- [47.7 DEADLINE QosPolicy on page 804](#)
- [47.17 OWNERSHIP QosPolicy on page 833](#)
- [47.18 OWNERSHIP\\_STRENGTH QosPolicy on page 836](#)

## 47.15.5 Applicable Entities

- [18.1 Topics on page 246](#)
- [Chapter 31 DataWriters on page 389](#)
- [Chapter 40 DataReaders on page 615](#)

## 47.15.6 System Resource Considerations

An internal thread in *Connex* will wake up periodically to check the liveliness of all the *DataWriters*. This happens both in the application that contains the *DataWriters* at the **lease\_duration** set on the *DataWriters* as well as the applications that contain the *DataReaders* at the **lease\_duration** set on the *DataReaders*. Therefore, as **lease\_duration** becomes smaller, more CPU will be used to wake up threads and perform checks. A short **lease\_duration** (or a high **assertions\_per\_lease\_duration**) set on *DataWriters* may also use more network bandwidth because liveliness packets are being sent at a higher rate—this is especially true when LIVELINESS kind is set to AUTOMATIC.

## 47.16 MULTI\_CHANNEL QosPolicy (DDS Extension)

This QosPolicy is used to partition the data published by a *DataWriter* across multiple *channels*. A *channel* is defined by a filter expression and a sequence of multicast locators.

By using this QosPolicy, a *DataWriter* can be configured to send data to different multicast groups based on the content of the data. Using syntax similar to those used in Content-Based Filters, you can associate different multicast addresses with filter expressions that operate on the values of the fields

within the data. When your application's code calls **write()**, data is sent to any multicast address for which the data passes the filter.

See [Multi-Channel DataWriters for High-Performance Filtering \(Chapter 36 on page 576\)](#) for complete documentation on *MultiChannel DataWriters*.

**Note:** Durable writer history is not supported for *MultiChannel DataWriters*; an error is reported if a *MultiChannel DataWriter* tries to configure Durable Writer History.

This QosPolicy includes the members presented in [Table 47.28 DDS\\_MultiChannelQosPolicy](#), [Table 47.29 DDS\\_ChannelSettings\\_t](#), and [Table 47.30 DDS\\_TransportMulticastSettings\\_t](#). For defaults and valid ranges, please refer to the API Reference HTML documentation.

**Table 47.28 DDS\_MultiChannelQosPolicy**

Type	Field Name	Description
DDS_ChannelSettingsSeq	channels	A sequence of channel settings used to configure the channels' properties. If the length of the sequence is zero, the QosPolicy will be ignored. See <a href="#">Table 47.29 DDS_ChannelSettings_t</a> .
char *	filter_name	Name of the filter class used to describe the filter expressions <sup>1</sup> . The following values are supported: DDS_SQLFILTER_NAME (see <a href="#">35.5 SQL Filter Expression Notation on page 555</a> ) DDS_STRINGMATCHFILTER_NAME (see <a href="#">35.6 STRINGMATCH Filter Expression Notation on page 564</a> ) More details are described in the API Reference HTML documentation.

**Table 47.29 DDS\_ChannelSettings\_t**

Type	Field Name	Description
DDS_TransportMulticastSettingsSeq	multicast_settings	A sequence of multicast settings used to configure the multicast addresses associated with a channel. <b>The sequence cannot be empty.</b> The maximum number of multicast locators in a channel is limited by default to 16. This is a hard limit that cannot be increased. However, this limit can be <i>decreased</i> by configuring the <i>DomainParticipant</i> property <code>dds.domain_participant.max_announced_locator_list_size</code> . See <a href="#">Table 47.30 DDS_TransportMulticastSettings_t</a> .
char *	filter_expression	A logical expression used to determine the data that will be published in the channel. <b>This string cannot be NULL.</b> An empty string always evaluates to TRUE. See <a href="#">35.5 SQL Filter Expression Notation on page 555</a> and <a href="#">35.6 STRINGMATCH Filter Expression Notation on page 564</a> for expression syntax.

<sup>1</sup> In Java and C#, you can access the names of the built-in filters by using `DomainParticipant.SQLFILTER_NAME` and `DomainParticipant.STRINGMATCHFILTER_NAME`.

Table 47.29 DDS\_ChannelSettings\_t

Type	Field Name	Description
DDS_Long	priority	A positive integer designating the relative priority of the channel, used to determine the transmission order of pending transmissions. Larger numbers have higher priority.  To use publication priorities, the <i>DataWriter's</i> <a href="#">47.20 PUBLISH_MODE QosPolicy (DDS Extension)</a> on <a href="#">page 843</a> must be set for asynchronous publishing and the <i>DataWriter</i> must use a FlowController that is configured for highest-priority-first (HPF) scheduling.  See <a href="#">34.4.4 Prioritized DDS Samples</a> on <a href="#">page 538</a> .

Table 47.30 DDS\_TransportMulticastSettings\_t

Type	Field Name	Description
DDS_StringSeq	transports	A sequence of transport aliases that specifies which transport should be used to publish multicast messages for this channel.
char *	receive_address	A multicast group address on which <i>DataReaders</i> subscribing to this channel will receive data.
DDS_Long	receive_port	The multicast port on which <i>DataReaders</i> subscribing to this channel will receive data.

The format of the **filter\_expression** should correspond to one of the following filter classes:

- DDS\_SQLFILTER\_NAME (see [35.5 SQL Filter Expression Notation](#) on [page 555](#))
- DDS\_STRINGMATCHFILTER\_NAME (see [35.6 STRINGMATCH Filter Expression Notation](#) on [page 564](#))

A *DataReader* can use the ContentFilteredTopic API (see [35.4 Using a ContentFilteredTopic](#) on [page 552](#)) to subscribe to a subset of the channels used by a *DataWriter*.

### 47.16.1 Example

See [Multi-Channel DataWriters for High-Performance Filtering](#) (Chapter 36 on [page 576](#)).

### 47.16.2 Properties

This QosPolicy cannot be modified after the *DataWriter* is created.

It does not apply to *DataReaders*, so there is no requirement that the publishing and subscribing sides use compatible values.

## 47.16.3 Related Qos Policies

- [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 714](#)

## 47.16.4 Applicable Entities

- [Chapter 31 DataWriters on page 389](#)

## 47.16.5 System Resource Considerations

The following fields in the [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 714](#) configure the resources associated with the channels stored in the MULTI\_CHANNEL QosPolicy:

- **channel\_seq\_max\_length**
- **channel\_filter\_expression\_max\_length**

For information about partitioning topic data across multiple channels, please refer to [Multi-Channel DataWriters for High-Performance Filtering \(Chapter 36 on page 576\)](#).

## 47.17 OWNERSHIP QosPolicy

The OWNERSHIP QosPolicy specifies whether a *DataReader* receives data for an instance of a *Topic* sent by multiple *DataWriters*.

For non-keyed *Topics*, there is only one instance of the *Topic*.

This policy includes the single member shown in [Table 47.31 DDS\\_OwnershipQosPolicy](#).

**Table 47.31 DDS\_OwnershipQosPolicy**

Type	Field Name	Description
DDS_OwnershipQosPolicyKind	kind	(default) DDS_SHARED_OWNERSHIP_QOS or DDS_EXCLUSIVE_OWNERSHIP_QOS

The **kind** of OWNERSHIP can be set to one of two values:

- **SHARED Ownership**

When OWNERSHIP is **SHARED**, and multiple *DataWriters* for the *Topic* publishes the value of the same instance, all the updates are delivered to subscribing *DataReaders*. So in effect, there is no “owner;” no single *DataWriter* is responsible for updating the value of an instance. The

subscribing application will receive modifications from all *DataWriters*.

- **EXCLUSIVE Ownership**

When OWNERSHIP is **EXCLUSIVE**, each instance can only be owned by one *DataWriter* at a time. This means that a single *DataWriter* is identified as the exclusive owner whose updates are allowed to modify the value of the instance for matching *DataReaders*. Other *DataWriters* may submit modifications for the instance, but only those made by the current owner are passed on to the *DataReaders*. If a non-owner *DataWriter* modifies an instance, no error or notification is made; the modification is simply ignored. The owner of the instance can change dynamically.

Note for non-keyed *Topics*, **EXCLUSIVE** ownership implies that *DataReaders* will pay attention to only one *DataWriter* at a time because there is only a single instance. For keyed *Topics*, *DataReaders* may actually receive data from multiple *DataWriters* when different *DataWriters* own different instances of the *Topic*.

This QosPolicy is often used to help users build systems that have redundant elements to safeguard against component or application failures. When systems have active and hot standby components, the Ownership QosPolicy can be used to ensure that data from standby applications are only delivered in the case of the failure of the primary.

The Ownership QosPolicy can also be used to create data channels or topics that are designed to be taken over by external applications for testing or maintenance purposes.

Although you can set the OWNERSHIP QosPolicy on *Topics*, its value can only be used to initialize the OWNERSHIP QosPolicies of either a *DataWriter* or *DataReader*. It does not directly affect the operation of *Connex*, see [18.1.3 Setting Topic QosPolicies on page 250](#).

### 47.17.1 How Connex Selects which DataWriter is the Exclusive Owner

When OWNERSHIP is **EXCLUSIVE**, the owner of an instance at any given time is the *DataWriter* with the highest [47.18 OWNERSHIP\\_STRENGTH QosPolicy on page 836](#) that is “alive” as defined by the [47.15 LIVELINESS QosPolicy on page 825](#)) and has not violated the [47.7 DEADLINE QosPolicy on page 804](#) of the *DataReader*. OWNERSHIP\_STRENGTH is simply an integer set by the *DataWriter*.

If the *Topic*’s data type is keyed (see [Chapter 8 DDS Samples, Instances, and Keys on page 17](#)), **EXCLUSIVE** ownership is determined on a per-instance basis. That is, the *DataWriter* owner of each instance is considered separately. A *DataReader* can receive values written by a lower strength *DataWriter* as long as those values are for instances that are not being written by a higher-strength *DataWriter*.

If there are multiple *DataWriters* with the same OWNERSHIP\_STRENGTH writing to the same instance, *Connex* resolves the tie by choosing the *DataWriter* with the smallest GUID (Globally

Unique Identifier, see [22.1 Simple Participant Discovery on page 310](#)). This means that different *DataReaders* (in different applications) of the same *Topic* will all choose the same *DataWriter* as the owner when there are multiple *DataWriters* with the same strength.

The owner of an instance can change when:

- A *DataWriter* with a higher OWNERSHIP\_STRENGTH publishes a value for the instance.
- The OWNERSHIP\_STRENGTH of the owning *DataWriter* is dynamically changed to be less than the strength of an existing *DataWriter* of the instance.
- The owning *DataWriter* stops asserting its LIVELINESS (the *DataWriter* dies).
- The owning *DataWriter* violates the DEADLINE QoSPolicy by not updating the value of the instance within the period set by the DEADLINE.

Note however, the change of ownership is not synchronous across different *DataReaders* in different participants. That is, *DataReaders* in different applications may not determine that the ownership of an instance has changed at exactly the same time.

## 47.17.2 Example

OWNERSHIP is really a property that is shared between *DataReaders* and *DataWriters* of a *Topic*. However, in a system, some *Topics* will be exclusively owned and others will be shared. System requirements will determine which are which.

An example of a *Topic* that may be shared is one that is used by applications to publish alarm messages. If the application detects an anomalous condition, it will use a *DataWriter* to write a *Topic* “Alarm.” Another application that records alarms into a system log file will have a *DataReader* that subscribes to “Alarm.” In this example, any number of applications can publish the “Alarm” message. There is no concept that only one application at a time is allowed to publish the “Alarm” message, so in this case, the OWNERSHIP of the *DataWriters* and *DataReaders* should be set to **SHARED**.

In a different part of the system, **EXCLUSIVE OWNERSHIP** may be used to implement redundancy in support of fault tolerance. Say, the distributed system controls a traffic system. It monitors traffic and changes the information posted on signs, the operation of metering lights, and the timing of traffic lights. This system must be tolerant to failure of any part of the system including the application that actually issues commands to change the lights at a particular intersection.

One way to implement fault tolerance is to create the system redundantly both in hardware and software. So if a piece of the running system fails, a backup can take over. In systems where failover from the primary to backup system must be seamless and transparent, the actual mechanics of failover must be fast, and the redundant component must immediately pickup where the failed component left off. For the network connections of the component, Connexant can provide redundant *DataWriter* and *DataReaders*.

In this case, you would not want the *DataReaders* to receive redundant messages from the redundant *DataWriters*. Instead you will want the *DataReaders* to only receive messages from the primary application and only from a backup application when a failure occurs. To continue our example, if we have redundant applications that all try to control the lights at an intersection, we would want the *DataReaders* on the light to receive messages only from the primary application. To do so, we should configure the *DataWriters* and *DataReaders* to have **EXCLUSIVE OWNERSHIP** and set the **OWNERSHIP\_STRENGTH** differently on different redundant applications to distinguish between primary and backup systems.

### 47.17.3 Properties

This QoSPolicy cannot be modified after the *Entity* is enabled.

It must be set to the same **kind** on both the publishing and subscribing sides. If a *DataWriter* and *DataReader* of the same topic are found to have different **kinds** set for the **OWNERSHIP** QoS, the **ON\_OFFERED\_INCOMPATIBLE\_QOS** and **ON\_REQUESTED\_INCOMPATIBLE\_QOS** statuses will be modified and the corresponding *Listeners* called for the *DataWriter* and *DataReader* respectively.

### 47.17.4 Related QoS Policies

- [47.7 DEADLINE QoS Policy on page 804](#)
- [47.15 LIVELINESS QoS Policy on page 825](#)
- [47.18 OWNERSHIP\\_STRENGTH QoS Policy below](#)

### 47.17.5 Applicable Entities

- [18.1 Topics on page 246](#)
- [Chapter 31 DataWriters on page 389](#)
- [Chapter 40 DataReaders on page 615](#)

### 47.17.6 System Resource Considerations

This QoSPolicy does not significantly impact the use of system resources.

## 47.18 OWNERSHIP\_STRENGTH QoS Policy

The **OWNERSHIP\_STRENGTH** QoS Policy is used to rank *DataWriters* of the same instance of a *Topic*, so that *Connex* can decide which *DataWriter* will have ownership of the instance when the [47.17 OWNERSHIP QoS Policy on page 833](#) is set to **EXCLUSIVE**.

It includes the member in [Table 47.32 DDS\\_OwnershipStrengthQoS Policy](#). For the default and valid range, please refer to the API Reference HTML documentation.

**Table 47.32 DDS\_OwnershipStrengthQosPolicy**

Type	Field Name	Description
DDS_Long	value	The strength value used to arbitrate among multiple <i>DataWriters</i> .

This QosPolicy only applies to *DataWriters* when **EXCLUSIVE OWNERSHIP** is used. The strength is simply an integer value, and the *DataWriter* with the largest value is the owner. A deterministic method is used to decide which *DataWriter* is the owner when there are multiple *DataWriters* that have equal strengths. See [47.17.1 How Connex Selects which DataWriter is the Exclusive Owner on page 834](#) for more details.

### 47.18.1 Example

Suppose there are two *DataWriters* sending DDS samples of the same *Topic* instance, one as the main *DataWriter*, and the other as a backup. If you want to make sure the *DataReader* always receive from the main one whenever possible, then set the main *DataWriter* to use a higher **ownership\_strength** value than the one used by the backup *DataWriter*.

### 47.18.2 Properties

This QosPolicy can be changed at any time.

It does not apply to *DataReaders*, so there is no requirement that the publishing and subscribing sides use compatible values.

### 47.18.3 Related QosPolicies

- [47.17 OWNERSHIP QosPolicy on page 833](#)

### 47.18.4 Applicable Entities

- [Chapter 31 DataWriters on page 389](#)

### 47.18.5 System Resource Considerations

The use of this policy does not significantly impact the use of resources.

## 47.19 PROPERTY QosPolicy (DDS Extension)

The PROPERTY QosPolicy stores name/value (string) pairs that can be used to configure certain parameters of *Connex* that are not exposed through formal QoS policies.

It can also be used to store and propagate application-specific name/value pairs that can be retrieved by user code during discovery. This is similar to the USER\_DATA QosPolicy, except this policy uses

(name, value) pairs, and you can select whether or not a particular pair should be propagated (included in the built-in topic). By default, properties are not propagated during discovery.

It includes the member in [Table 47.33 DDS\\_PropertyQoSPolicy](#).

**Table 47.33 DDS\_PropertyQoSPolicy**

Type	Field Name	Description
DDS_PropertySeq	value	A sequence of: (name, value) pairs and booleans that indicate whether the pair should be propagated (included in the entity's built-in topic upon discovery).

The Property QoS stores name/value pairs for an Entity. Both the name and value are strings. Certain configurable parameters for Entities that do not have a formal DDS QoS definition may be configured via this QoS by using a predefined name and the desired setting in string form.

You can find a complete list of predefined properties in the [Property Reference Guide](#).

You can manipulate the sequence of properties (name, value pairs) with the standard methods available for sequences. You can also use the helper class, `DDSPropertyQoSPolicyHelper`, which provides another way to work with a `PropertyQoSPolicy` object.

The `PropertyQoSPolicy` may be used to configure:

- Durable writer history (see [21.3.2 How To Configure Durable Writer History on page 297](#))
- Durable reader state (see [21.4.4 How To Configure a DataReader for Durable Reader State on page 303](#))
- Built-in and extension Transport Plugins (see [51.6 Setting Builtin Transport Properties with the PropertyQoSPolicy on page 960](#), [53.2 Configuring the TCP Transport on page 1055](#)).
- Automatic registration of built-in types (see [17.2.1 Registering Built-in Types on page 122](#))
- [16.3.15 Configuring the Clock per DomainParticipant on page 105](#)
- [31.18 Turbo Mode and Automatic Throttling for DataWriter Performance—Experimental Features on page 444](#)
- Location or content of your license from RTI (see *License Management*, in the [RTI Connex Installation Guide](#))

In addition, you can add your own name/value pairs to the Property QoS of an Entity. Start them with a prefix other than `dds.`, `com.rti.`, or `rti.`, so that they do not fail validation. (See [47.19.1 Property Validation on page 840](#).) You may also use this QoSPolicy to direct *Connex* to propagate these name/value pairs with the discovery information for the Entity. Applications that discover the Entity can then access the user-specific name/value pairs in the discovery information of the remote Entity. This allows

you to add meta-information about an Entity for application-specific use, for example, authentication/authorization certificates (which can also be done using the User or Group Data QoS).

Reasons for using the PropertyQoS Policy include:

- Some features can only be configured through the PropertyQoS Policy, not through other QoS or APIs (for example, Durable Reader State, Durable Writer History, Built-in Types, Monotonic Clock).
- Alternative way to configure built-in transports settings. For example, to use non-default values for the built-in transports without using the PropertyQoS Policy, you would have to create a *DomainParticipant* disabled, change the built-in transport property settings, then enable the *DomainParticipant*. Using the PropertyQoS Policy to configure built-in transport settings will save you the work of enabling and disabling the *DomainParticipant*.

**Note:** Starting with *Connex* 6.0.0, you can also configure the built-in transport settings using the following XML tags under `<transport_builtin>`: `<udp4>`, `<udp6>`, `<shmem>`, `<udp4_wan>`. This is recommended over using the PropertyQoS Policy. See [50.4.6 Transport Properties on page 936](#).

When using non-C/C++ and Java APIs, the transport configuration must take place through the PropertyQoS Policy (not through the transport property structures) or the `<transport_builtin>` XML tags (for *Connex* 6.0.0 and higher).

- Alternative way to support multiple instances of built-in transports (without using Transport API).
- Alternative way to dynamically load and configure extension transports (such as *RTI TCP Transport*<sup>1</sup>) in C/C++ language bindings. If the extension plugin is installed using the **register\_transport()** API instead, the library of the extension transport will need to be linked into your application and may require recompilation.
- Alternative way to provide a license for platforms that do not support a file system, or if a default license location is not feasible and environment variables are not supported.

The PropertyQoS PolicyHelper operations are described in [Table 47.34 PropertyQoS PolicyHelper Operations](#). For more information, see the API Reference HTML documentation.

<sup>1</sup>*RTI TCP Transport* is included with your *Connex* distribution but is not a built-in transport and therefore not enabled by default.

**Table 47.34 PropertyQoSPolicyHelper Operations**

Operation	Description
get_number_of_properties	Gets the number of properties in the input policy.
assert_property	Asserts the property identified by name in the input policy. (Either adds it, or replaces an existing one.)
add_property	Adds a new property to the input policy.
assert_pointer_property	Asserts the property identified by name in the input policy. Used when the property to store is a pointer.
add_pointer_property	Adds a new property to the input policy. Used when the property to store is a pointer.
lookup_property	Searches for a property in the input policy given its name.
remove_property	Removes a property from the input policy.
get_properties	Retrieves a list of properties whose names match the input prefix.

## 47.19.1 Property Validation

All the properties that *Connex*t provides (which begin with **dds.**, **com.rti.**, or **rti.**) are validated when the entity or the plugin is created. This validation is done to avoid using an unknown or incorrect property name (for example, due to a typo). Without this validation, *Connex*t ignores the unknown property name, and you might not know why the property's configuration isn't being applied.

By default, at the creation of an entity or a plugin, if you specify an incorrect property name, *Connex*t logs an exception similar to the following:

- Entity:

```
DDS_PropertyQoSPolicy_validatePropertyNames:Unexpected property: dds.type_
consistnecy.ignore_sequence_bounds. Closest valid property: dds.type_
consistency.ignore_sequence_bounds
DDS_DataReaderQoS_is_consistentI:inconsistent QoS property
DDS_Subscriber_create_datareader_disabledI:ERROR: Inconsistent QoS
```

- Plugin, such as TCPv4:

```
DDS_PropertyQoSPolicy_validate_plugin_property_suffixes:Unexpected property:
dds.transport.TCPv4.tcpl.invalidPropertyTest. Closest valid property:
dds.transport.TCPv4.tcpl.aliases
NDDS_Transport_TCPv4_Property_parseDDSProperties:Inconsistent QoS property:
dds.transport.TCPv4.
NDDS_Transport_TCPv4_create:!get transport TCPv4 plugin property from DDS Property
```

You can configure the behavior of this validation by setting a property at the *DomainParticipant* level. The *DomainParticipant's DataWriters* and *DataReaders* use the participant's setting. Or you can set the property at the plugin level.

- At the entity-level setting, you can set the property **dds.participant.property\_validation\_action** to any of the following options:
  - (default) `VALIDATION_ACTION_EXCEPTION`: validate properties. Upon failure, log errors and fail.
  - `VALIDATION_ACTION_SKIP`: skip validation.
  - `VALIDATION_ACTION_WARNING`: validate properties. Upon failure, log warnings and do not fail.
- At the plugin level setting, you can set the property `<plugin_name>.property_validation_action`:
  - Options:
    - `VALIDATION_ACTION_EXCEPTION`: validate properties. Upon failure, log errors and fail.
    - `VALIDATION_ACTION_SKIP`: skip validation.
    - `VALIDATION_ACTION_WARNING`: validate properties. Upon failure, log warnings and do not fail.
  - If the property is not set, the plugin property validation behavior will be the same as that of the *DomainParticipant*, which by default is `VALIDATION_ACTION_EXCEPTION`.
  - For example, to set the **property\_validation\_action** for the **dds.transport.TCPv4.tcp1** transport plugin via XML:

```

<domain_participant_qos>
  <property>
    <value>
      <element>
        <name>dds.transport.load_plugins</name>
        <value>dds.transport.TCPv4.tcp1</value>
      </element>
      <element>
        <name>dds.transport.TCPv4.tcp1.property_validation_action</name>
        <value>VALIDATION_ACTION_WARNING</value>
      </element>
    </value>
  </property>
</domain_participant_qos>

```

In general, it is recommended that you use **dds.participant.property\_validation\_action** to control the validation of the properties for both the *Connex* core libraries and any plugins you might use. However, there are cases where you might want to configure different behaviors for the core libraries and the plugins. For example, if you are running a customized version of the plugins that supports a new, experimental property, you will need to disable the *DomainParticipant* validation via **dds.-participant.property\_validation\_action**, but still keep the plugin validation (for example,

**dds.transport.TCPv4.tcp1.property\_validation\_action**). Here's an example of disabling the *DomainParticipant* level validation and enabling a plugin level validation:

```
<domain_participant_qos>
  <property>
    <value>
      <element>
        <name>dds.participant.property_validation_action</name>
        <value>VALIDATION_ACTION_SKIP</value>
      </element>
      <element>
        <name>dds.transport.TCPv4.tcp1.property_validation_action</name>
        <value>VALIDATION_ACTION_EXCEPTION</value>
      </element>
    </value>
  </property>
</domain_participant_qos>
```

Note that the validation is sequential: first the property is validated when the *DomainParticipant* is created, then it is validated when the plugin is created. For example, consider that the *DomainParticipant* sets the property **dds.participant.property\_validation\_action** to `VALIDATION_ACTION_EXCEPTION`, but the plugin is configured to skip the unknown property. In this case, *DomainParticipant* creation will fail, and the plugin will never get created. As described above, if you are customizing the plugin, set the validation to `VALIDATION_ACTION_SKIP` at the *DomainParticipant* level, then set the plugin property validation to `VALIDATION_ACTION_EXCEPTION`. By doing that, the properties will be validated just at the plugin level.

You can find a complete list of the *Connex* predefined properties in the [Property Reference Guide](#).

## 47.19.2 Properties

This QosPolicy can be changed at any time.

There is no requirement that the publishing and subscribing sides use compatible values.

### 47.19.3 Related QosPolicies

- [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 714](#)

### 47.19.4 Applicable Entities

- [Chapter 31 DataWriters on page 389](#)
- [Chapter 40 DataReaders on page 615](#)
- [16.3 DomainParticipants on page 81](#)

## 47.19.5 System Resource Considerations

The [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\)](#) on page 714 contains several fields for configuring the resources associated with the properties stored in this QosPolicy.

## 47.20 PUBLISH\_MODE QosPolicy (DDS Extension)

This QosPolicy determines the *DataWriter's* publishing mode, either asynchronous or synchronous.

The publishing mode controls whether data is written synchronously—in the context of the user thread when calling `write()`, or asynchronously—in the context of a separate thread internal to *Connex*.

**Note:** For information on asynchronous *DataWriters* and sender-side filtering, see [35.1 Where Filtering is Applied—Publishing vs. Subscribing Side](#) on page 547.

Each *Publisher* spawns a single asynchronous publishing thread (set in its [46.1 ASYNCHRONOUS\\_PUBLISHER QosPolicy \(DDS Extension\)](#) on page 740) to serve all its asynchronous *DataWriters*.

When data is written asynchronously, a FlowController ([34.4 FlowControllers \(DDS Extension\)](#) on page 532), identified by `flow_controller_name`, can be used to shape the network traffic. The FlowController's properties determine when the asynchronous publishing thread is allowed to send data and how much.

The fastest way for *Connex* to send data is for the user thread to execute the middleware code that actually sends the data itself. However, there are times when user applications may need or want an internal middleware thread to send the data instead. For instance, for sending large data reliably, an asynchronous thread must be used (see [46.1 ASYNCHRONOUS\\_PUBLISHER QosPolicy \(DDS Extension\)](#) on page 740). See also [34.3 Large Data Fragmentation](#) on page 524.

This QosPolicy can select a FlowController to prioritize or shape the data flow sent by a *DataWriter* to *DataReaders*. Shaping a data flow usually means limiting the maximum data rates with which the middleware will send data for a *DataWriter*. The FlowController will buffer data sent faster than the maximum rate by the *DataWriter*, and then only send the excess data when the user send rate drops below the maximum rate.

If `kind` is set to `DDS_ASYNCHRONOUS_PUBLISH_MODE_QOS`, the flow controller referred to by `flow_controller_name` must exist. Otherwise, the setting will be considered inconsistent.

This QosPolicy includes the members in [Table 47.35 DDS\\_PublishModeQosPolicy](#). For the defaults, please refer to the API Reference HTML documentation.

Table 47.35 DDS\_PublishModeQosPolicy

Type	Field Name	Description
DDS_PublishModeQosPolicyKind	kind	Either: <ul style="list-style-type: none"> <li>• DDS_ASYNCHRONOUS_PUBLISH_MODE_QOS</li> <li>• DDS_SYNCHRONOUS_PUBLISH_MODE_QOS</li> </ul>
char*	flow_controller_name	Name of the associated flow controller. There are three built-in FlowControllers: <ul style="list-style-type: none"> <li>• DDS_DEFAULT_FLOW_CONTROLLER_NAME</li> <li>• DDS_FIXED_RATE_FLOW_CONTROLLER_NAME</li> <li>• DDS_ON_DEMAND_FLOW_CONTROLLER_NAME</li> </ul> You may also create your own FlowControllers. See <a href="#">34.4 FlowControllers (DDS Extension) on page 532</a> .
DDS_Long	priority	A positive integer designating the relative priority of the <i>DataWriter</i> , used to determine the transmission order of pending writes. To use publication priorities, this QosPolicy's <b>kind</b> must be DDS_ASYNCHRONOUS_PUBLISH_MODE_QOS and the <i>DataWriter</i> must use a FlowController with a highest-priority first (HPF) <b>scheduling_policy</b> . See <a href="#">34.4.4 Prioritized DDS Samples on page 538</a> .

The maximum number of DDS samples that will be coalesced depends on **NDDS\_Transport\_Property\_t::gather\_send\_buffer\_count\_max** (each DDS sample requires at least 2-4 gather-send buffers). Performance can be improved by increasing **NDDS\_Transport\_Property\_t::gather\_send\_buffer\_count\_max**. Note that the maximum value is operating system dependent.

*Connex* queues DDS samples until they can be sent by the asynchronous publishing thread (as determined by the corresponding FlowController).

The number of DDS samples that will be queued is determined by the [47.12 HISTORY QosPolicy on page 818](#): when using **KEEP\_LAST**, the most recent **depth** DDS samples are kept in the queue.

Once unsent DDS samples are removed from the queue, they are no longer available to the asynchronous publishing thread and will therefore never be sent.

Unless **flow\_controller\_name** points to one of the built-in FlowControllers, finalizing the *DataWriter*-Qos will also free the string pointed to by **flow\_controller\_name**. Therefore, you should use **DDS\_String\_dup()** before passing the string to **flow\_controller\_name**, or reset **flow\_controller\_name** to NULL before the destructing /finalizing the QoS.

#### Advantages of Asynchronous Publishing:

Asynchronous publishing may increase latency, but offers the following advantages:

- The **write()** call does not make any network calls and is therefore faster and more deterministic. This becomes important when the user thread is executing time-critical code.
- When data is written in bursts or when sending large data types as multiple fragments, a flow controller can throttle the send rate of the asynchronous publishing thread to avoid flooding the network.
- Asynchronously written DDS samples for the same destination will be coalesced into a single network packet which reduces bandwidth consumption.

## 47.20.1 Properties

This QosPolicy cannot be modified after the *DataWriter* is created.

Since it is only for *DataWriters*, there are no compatibility restrictions for how it is set on the publishing and subscribing sides.

## 47.20.2 Related QosPolicies

- [46.1 ASYNCHRONOUS\\_PUBLISHER QosPolicy \(DDS Extension\) on page 740](#)
- [47.12 HISTORY QosPolicy on page 818](#)

## 47.20.3 Applicable Entities

- [Chapter 31 DataWriters on page 389](#)

## 47.20.4 System Resource Considerations

See [47.22.1 Configuring Resource Limits for Asynchronous DataWriters on page 852](#).

System resource usage depends on the settings in the corresponding FlowController (see [34.4 FlowControllers \(DDS Extension\) on page 532](#)).

## 47.21 RELIABILITY QosPolicy

This RELIABILITY QosPolicy determines whether or not data published by a *DataWriter* will be reliably delivered by *Connex*t to matching *DataReaders*. The reliability protocol used by *Connex*t is discussed in [Reliability Models for Sending Data \(Chapter 32 on page 446\)](#).

The reliability of a connection between a *DataWriter* and *DataReader* is entirely user configurable. It can be done on a per *DataWriter/DataReader* connection. A connection may be configured to be "best effort" which means that *Connex*t will not use any resources to monitor or guarantee that the data sent by a *DataWriter* is received by a *DataReader*.

For some use cases, such as the periodic update of sensor values to a GUI displaying the value to a person, "best effort" delivery is often good enough. It is certainly the fastest, most efficient, and least

resource-intensive (CPU and network bandwidth) method of getting the newest/latest value for a topic from *DataWriters* to *DataReaders*. But there is no guarantee that the data sent will be received. It may be lost due to a variety of factors, including data loss by the physical transport such as wireless RF or even Ethernet. Packets received out of order are dropped and reported as lost with the reason LOST\_BY\_WRITER (see [40.7.7 SAMPLE\\_LOST Status on page 636](#)).

However, there are data streams (topics) in which you want an absolute guarantee that all data sent by a *DataWriter* is received reliably by *DataReaders*. This means that *Connex*t must check whether or not data was received, and repair any data that was lost by resending a copy of the data as many times as it takes for the *DataReader* to receive the data.

*Connex*t uses a reliability protocol configured and tuned by these QoS policies:

- [47.12 HISTORY QoSPolicy on page 818](#)
- [47.5 DATA\\_WRITER\\_PROTOCOL QoSPolicy \(DDS Extension\) on page 788](#)
- [48.1 DATA\\_READER\\_PROTOCOL QoSPolicy \(DDS Extension\) on page 871](#)
- [47.22 RESOURCE\\_LIMITS QoSPolicy on page 850](#)

The Reliability QoS policy is simply a switch to turn on the reliability protocol for a *DataWriter/DataReader* connection. The level of reliability provided by *Connex*t is determined by the configuration of the aforementioned QoS policies.

You can configure *Connex*t to deliver ALL data in the order they were sent (also known as absolute or strict reliability). Or, as a trade-off for less memory, CPU, and network usage, you can choose a reduced level of reliability where only the last N values are guaranteed to be delivered reliably to *DataReaders* (where N is user-configurable). With the reduced level of reliability, there are no guarantees that the data sent before the last N are received. Only the last N data packets are monitored and repaired if necessary.

It includes the members in [Table 47.36 DDS\\_ReliabilityQoSPolicy](#). For defaults and valid ranges, please refer to the API Reference HTML documentation.

**Table 47.36 DDS\_ReliabilityQoSPolicy**

Type	Field Name	Description
DDS_ReliabilityQoSPolicyKind	kind	Can be either: <ul style="list-style-type: none"> <li>• DDS_BEST_EFFORT_RELIABILITY_QOS: DDS data samples are sent once and missed samples are acceptable.</li> <li>• DDS_RELIABLE_RELIABILITY_QOS: <i>Connex</i>t will make sure that data sent is received and missed DDS samples are resent.</li> </ul>
DDS_Duration_t	max_blocking_time	How long a <i>DataWriter</i> can block on a write() when the send queue is full due to unacknowledged messages. (Has no meaning for <i>DataReaders</i> .)

Table 47.36 DDS\_ReliabilityQosPolicy

Type	Field Name	Description
DDS_ReliabilityQosPolicy-AcknowledgmentModeKind	acknowledgment_kind	<p>Kind of reliable acknowledgment.</p> <p>Only applies when <b>kind</b> is RELIABLE.</p> <p>Sets the kind of acknowledgments supported by a <i>DataWriter</i> and sent by <i>DataReader</i>.</p> <p>Possible values:</p> <ul style="list-style-type: none"> <li>• DDS_PROTOCOL_ACKNOWLEDGMENT_MODE</li> <li>• DDS_APPLICATION_AUTO_ACKNOWLEDGMENT_MODE</li> <li>• DDS_APPLICATION_EXPLICIT_ACKNOWLEDGMENT_MODE</li> </ul> <p>See <a href="#">31.12.1 Application Acknowledgment Kinds on page 418</a></p>

The **kind** of RELIABILITY can be either:

- **BEST\_EFFORT**

*Connex* will send DDS data samples only once to *DataReaders*. No effort or resources are spent to track whether or not sent DDS samples are received. Minimal resources are used. This is the most deterministic method of sending data since there is no indeterministic delay that can be introduced by buffering or resending data. DDS data samples may be lost. This setting is good for periodic data.

- **RELIABLE**

*Connex* will send DDS samples reliably to *DataReaders*—buffering sent data until they have been acknowledged as being received by *DataReaders* and resending any DDS samples that may have been lost during transport. Additional resources configured by the HISTORY and RESOURCE\_LIMITS QosPolicies may be used. Extra packets will be sent on the network to query (heartbeat) and acknowledge the receipt of DDS samples by the *DataReader*. This setting is a good choice when guaranteed data delivery is required; for example, sending events or commands.

To send *large* data reliably, you will also need to set the [47.20 PUBLISH\\_MODE QosPolicy \(DDS Extension\) on page 843](#) **kind** to DDS\_ASYNCHRONOUS\_PUBLISH\_MODE\_QOS. *Large* in this context means that the data size is larger than the transport **message\_size\_max** property value. See [34.3 Large Data Fragmentation on page 524](#).

While a *DataWriter* sends data reliably, the [47.12 HISTORY QosPolicy on page 818](#) and [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#) determine how many DDS samples can be stored while waiting for acknowledgements from *DataReaders*. A DDS sample that is sent reliably is entered in the *DataWriter*'s send queue awaiting acknowledgement from *DataReaders*. How many DDS samples that the *DataWriter* is allowed to store in the send queue for a data-instance depends on the **kind** of the

HISTORY QoS as well as the **max\_samples\_per\_instance** and **max\_samples** parameter of the RESOURCE\_LIMITS QoS.

If the HISTORY **kind** is **KEEP\_LAST**, then the *DataWriter* is allowed to have the HISTORY **depth** number of DDS samples per instance of the *Topic* in the send queue. Should the number of unacknowledged DDS samples in the send queue for a data-instance reach the HISTORY **depth**, then the next DDS sample written by the *DataWriter* for the instance will overwrite the oldest DDS sample for the instance in the queue. This implies that an unacknowledged DDS sample may be overwritten and thus lost. So even if the RELIABILITY **kind** is **RELIABLE**, if the HISTORY **kind** is **KEEP\_LAST**, it is possible that some data sent by the *DataWriter* will not be delivered to the *DataReader*. What is guaranteed is that if the *DataWriter* stops writing, the last *N* DDS samples that the *DataWriter* wrote will be delivered reliably; where *n* is the value of the HISTORY **depth**.

However, if the HISTORY **kind** is **KEEP\_ALL**, then when the send queue is filled with unacknowledged DDS samples (either due to the number of unacknowledged DDS samples for an instance reaching the RESOURCE\_LIMITS **max\_samples\_per\_instance** value or the total number of unacknowledged DDS samples have reached the size of the send queue as specified by RESOURCE\_LIMITS **max\_samples**), the next **write()** operation on the *DataWriter* will block until either a DDS sample in the queue has been fully acknowledged by *DataReaders* and thus can be overwritten or a timeout of RELIABILITY **max\_blocking\_period** has been reached.

If there is still no space in the queue when **max\_blocking\_time** is reached, the **write()** call will return a failure with the error code **DDS\_RETCODE\_TIMEOUT**.

Thus for strict reliability—a guarantee that all DDS data samples sent by a *DataWriter* are received by *DataReaders*—you must use a RELIABILITY **kind** of **RELIABLE** and a HISTORY **kind** of **KEEP\_ALL** for both the *DataWriter* and the *DataReader*.

Although you can set the RELIABILITY QoSPolicy on *Topics*, its value can only be used to initialize the RELIABILITY QoS Policies of either a *DataWriter* or *DataReader*. It does not directly affect the operation of *Connex*, see [18.1.3 Setting Topic QoS Policies on page 250](#).

## 47.21.1 Example

This QoSPolicy is used to achieve reliable communications, which is discussed in [Reliability Models for Sending Data \(Chapter 32 on page 446\)](#) and [32.4.1 Enabling Reliability on page 453](#).

## 47.21.2 Properties

This QoSPolicy *cannot* be modified after the Entity has been enabled.

The *DataWriter* and *DataReader* must use compatible settings for this QoSPolicy. To be compatible, the *DataWriter* and *DataReader* must use one of the valid combinations for the Reliability **kind** (see [Table 47.37 Valid Combinations of Reliability ‘kind’](#)), and one of the valid combinations for the **acknowledgment\_kind** (see [Table 47.38 Valid Combinations of Reliability ‘acknowledgment\\_kind’](#)):

Table 47.37 Valid Combinations of Reliability 'kind'

		DataReader requests:	
		BEST_EFFORT	RELIABLE
DataWriter offers:	BEST_EFFORT	compatible	incompatible
	RELIABLE	compatible	compatible

Table 47.38 Valid Combinations of Reliability 'acknowledgment\_kind'

		DataReader requests:		
		PROTOCOL	APPLICATION_AUTO	APPLICATION_EXPLICIT
DataWriter offers:	PROTOCOL	compatible	incompatible	incompatible
	APPLICATION_AUTO	compatible	compatible	compatible
	APPLICATION_EXPLICIT	compatible	compatible	compatible

If this QosPolicy is found to be incompatible, statuses **ON\_OFFERED\_INCOMPATIBLE\_QOS** and **ON\_REQUESTED\_INCOMPATIBLE\_QOS** will be modified and the corresponding *Listeners* called for the *DataWriter* and *DataReader*, respectively.

There are no compatibility issues regarding the value of **max\_blocking\_wait**, since it does not apply to *DataReaders*.

### 47.21.3 Related QosPolicies

- [47.12 HISTORY QosPolicy on page 818](#)
- [47.20 PUBLISH\\_MODE QosPolicy \(DDS Extension\) on page 843](#)
- [47.22 RESOURCE\\_LIMITS QosPolicy on the next page](#)

### 47.21.4 Applicable Entities

- [18.1 Topics on page 246](#)
- [Chapter 31 DataWriters on page 389](#)
- [Chapter 40 DataReaders on page 615](#)

## 47.21.5 System Resource Considerations

Setting the **kind** to **RELIABLE** will cause *Connex*t to use up more resources to monitor and maintain a reliable connection between a *DataWriter* and all of its reliable *DataReaders*. This includes the use of extra CPU and network bandwidth to send and process heartbeat, ACK/NACK, and repair packets (see [Reliability Models for Sending Data \(Chapter 32 on page 446\)](#)).

Setting **max\_blocking\_time** to a non-zero number may block the sending thread when the RELIABILITY kind is **RELIABLE**.

## 47.22 RESOURCE\_LIMITS QoSPolicy

For the reliability protocol (and the [47.9 DURABILITY QoSPolicy on page 809](#)), this QoSPolicy determines the actual maximum queue size when the [47.12 HISTORY QoSPolicy on page 818](#) is set to **KEEP\_ALL**.

In general, this QoSPolicy is used to limit the amount of system memory that *Connex*t can allocate. For embedded real-time systems and safety-critical systems, pre-determination of maximum memory usage is often required. In addition, dynamic memory allocation could introduce non-deterministic latencies in time-critical paths.

It includes the members in [Table 47.39 DDS\\_ResourceLimitsQoSPolicy](#). For defaults and valid ranges, please refer to the API Reference HTML documentation.

**Table 47.39 DDS\_ResourceLimitsQoSPolicy**

Type	Field Name	Description
DDS_Long	max_samples	Maximum number of live DDS samples that <i>Connex</i> t can store for a <i>DataWriter/DataReader</i> . This is a physical limit.
DDS_Long	max_instances	Maximum number of active instances that can be managed by a <i>DataWriter/DataReader</i> . (See <a href="#">40.8.7 Active State and Minimum State on page 649</a> .) For <i>DataReaders</i> , <b>max_instances</b> must be $\leq$ <b>max_total_instances</b> in the <a href="#">48.2 DATA_READER_RESOURCE_LIMITS QoSPolicy (DDS Extension) on page 876</a> . See also: <a href="#">47.22.2 Example on page 852</a> .
DDS_Long	max_samples_per_instance	On a <i>DataWriter</i> , this resource limit represents the maximum number of DDS samples of any one instance that <i>Connex</i> t will store for a <i>DataWriter</i> . On a <i>DataReader</i> , this resource limit represents the maximum number of DDS samples of any one instance that are stored in the <i>DataReader</i> output queue—that is, the queue from which the application takes/reads samples. For keyed types and <i>DataReaders</i> , this value only applies to DDS samples with an instance state of <b>DDS_ALIVE_INSTANCE_STATE</b> . If a keyed <i>Topic</i> is not used, then <b>max_samples_per_instance</b> must equal <b>max_samples</b> . How this property behaves depends on your HISTORY and RELIABILITY QoS configurations. See <a href="#">47.12 HISTORY QoSPolicy on page 818</a> .

Table 47.39 DDS\_ResourceLimitsQosPolicy

Type	Field Name	Description
DDS_Long	initial_samples	Initial number of DDS samples that <i>Connex</i> t will store for a <i>DataWriter/DataReader</i> . (DDS extension)
DDS_Long	initial_instances	Initial number of instances that can be managed by a <i>DataWriter/DataReader</i> . (DDS extension)
DDS_Long	instance_hash_buckets	Number of hash buckets, which are used by <i>Connex</i> t to facilitate instance lookup. (DDS extension).

One of the most important fields is **max\_samples**, which sets the size and causes memory to be allocated for the send or receive queues. For information on how this policy affects reliability, see [32.4.2 Tuning Queue Sizes and Other Resource Limits on page 454](#).

When a *DataWriter* or *DataReader* is created, the **initial\_instances** and **initial\_samples** parameters determine the amount of memory first allocated for those Entities. As the application executes, if more space is needed in the send/receive queues to store DDS samples or as more instances are created, then *Connex*t will automatically allocate memory until the limits of **max\_instances** and **max\_samples** are reached.

You may set **initial\_instances = max\_instances** and **initial\_samples = max\_samples** if you do not want *Connex*t to dynamically allocate memory after initialization.

For keyed *Topics*, the **max\_samples\_per\_instance** field in this policy represents the maximum number of DDS samples with the same key that are allowed to be stored by a *DataWriter* (in the *DataWriter's* queue) or by the *DataReader* (in the *DataReader's* output queue—that is, the queue from which the application takes/reads samples). The **max\_samples\_per\_instance** field is a logical limit. The hard physical limit is determined by **max\_samples**. However, because the theoretical number of instances may be quite large (as set by **max\_instances**), you may not want *Connex*t to allocate the total memory needed to hold the maximum number of DDS samples per instance for all possible instances (**max\_samples\_per\_instance \* max\_instances**) because during normal operations, the application will never have to hold that much data for the Entity.

So it is possible that an Entity will hit the physical limit **max\_samples** before it hits the **max\_samples\_per\_instance** limit for a particular instance. However, *Connex*t must be able to store **max\_samples\_per\_instance** for at least one instance. Therefore, **max\_samples\_per\_instance must be <= max\_samples**.

If a keyed data type is not used, there is only a single instance of the *Topic*, so **max\_samples\_per\_instance must equal max\_samples**.

Once a physical or logical limit is hit, then how *Connex*t deals with new DDS data samples being sent or received for a *DataWriter* or *DataReader* is described in the [47.12 HISTORY QosPolicy on](#)

[page 818](#) setting of `DDS_KEEP_ALL_HISTORY_QOS`. It is closely tied to whether or not a reliable connection is being maintained.

Although you can set the `RESOURCE_LIMITS` QoSPolicy on *Topics*, its value can only be used to initialize the `RESOURCE_LIMITS` QoSPolicies of either a *DataWriter* or *DataReader*. It does not directly affect the operation of *Connex*, see [18.1.3 Setting Topic QoS Policies on page 250](#).

## 47.22.1 Configuring Resource Limits for Asynchronous DataWriters

When using an asynchronous *Publisher*, if a call to `write()` is blocked due to a resource limit, the block will last until the timeout period expires, which will prevent others from freeing the resource. To avoid this situation, make sure that the *DomainParticipant*'s **outstanding\_asynchronous\_sample\_allocation** in the [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QoSPolicy \(DDS Extension\) on page 714](#) is always greater than the sum of all asynchronous *DataWriters*' `max_samples`.

### 47.22.2 Example

If you want to be able to store `max_samples_per_instance` for every instance, then you should set

```
max_samples >= max_instances * max_samples_per_instance
```

But if you want to save memory and you do not expect that the running application will ever reach the case where it will see `max_instances` of instances, then you may use a smaller value for `max_samples` to save memory.

In any case, there is a lower limit for `max_samples`:

```
max_samples >= max_samples_per_instance
```

If the [47.12 HISTORY QoSPolicy on page 818](#)'s `kind` is set to `KEEP_LAST`, then you should set:

```
max_samples_per_instance = HISTORY.depth
```

### 47.22.3 Properties

This QoSPolicy cannot be modified after the Entity is enabled.

There are no requirements that the publishing and subscribing sides use compatible values.

### 47.22.4 Related QoS Policies

- [47.12 HISTORY QoSPolicy on page 818](#)
- [47.21 RELIABILITY QoSPolicy on page 845](#)
- For *DataReaders*, `max_instances` must be  $\leq$  `max_total_instances` in the [48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QoSPolicy \(DDS Extension\) on page 876](#)

## 47.22.5 Applicable Entities

- [18.1 Topics on page 246](#)
- [Chapter 31 DataWriters on page 389](#)
- [Chapter 40 DataReaders on page 615](#)

## 47.22.6 System Resource Considerations

Larger **initial\_\*** numbers will increase the initial system memory usage. Larger **max\_\*** numbers will increase the worst-case system memory usage.

Increasing **instance\_hash\_buckets** speeds up instance-lookup time but also increases memory usage.

## 47.23 SERVICE QosPolicy (DDS Extension)

The SERVICE QosPolicy is intended for use by RTI infrastructure services. User applications should not modify its value. It includes the member in [Table 47.40 DDS\\_ServiceQosPolicy](#).

**Table 47.40 DDS\_ServiceQosPolicy**

Type	Field Name	Description
DDS_ServiceQosPolicyKind	kind	Kind of service associated with the entity. Possible values: <ul style="list-style-type: none"> <li>• DDS_NO_SERVICE_QOS,</li> <li>• DDS_PERSISTENCE_SERVICE_QOS,</li> <li>• DDS_QUEUEING_SERVICE_QOS,</li> <li>• DDS_ROUTING_SERVICE_QOS,</li> <li>• DDS_RECORDING_SERVICE_QOS,</li> <li>• DDS_REPLAY_SERVICE_QOS,</li> <li>• DDS_DATABASE_INTEGRATION_SERVICE_QOS</li> <li>• DDS_WEB_INTEGRATION_SERVICE_QOS</li> </ul>

An application can determine the kind of service associated with a discovered *DataWriter* and *DataReader* by looking at the **service** field in the *PublicationBuiltinTopicData* and *SubscriptionBuiltinTopicData* structures (see [Chapter 28 Accessing Discovery Information through Built-In Topics on page 359](#)).

### 47.23.1 Properties

This QosPolicy cannot be modified after the Entity is enabled.

There are no requirements that the publishing and subscribing sides use compatible values.

## 47.23.2 Related QosPolicies

None

## 47.23.3 Applicable Entities

- [Chapter 31 DataWriters on page 389](#)
- [Chapter 40 DataReaders on page 615](#)
- [16.3 DomainParticipants on page 81](#)

## 47.23.4 System Resource Considerations

None.

## 47.24 TOPIC\_QUERY\_DISPATCH\_QosPolicy (DDS Extension)

The TOPIC\_QUERY\_DISPATCH QosPolicy configures the ability of a *DataWriter* to publish historical samples in response to a TopicQuery (see [Topic Queries \(Chapter 60 on page 1142\)](#)).

It contains the members listed in [Table 47.41 DDS\\_TopicQueryDispatchQosPolicy](#).

**Table 47.41 DDS\_TopicQueryDispatchQosPolicy**

Type	Field Name	Description
DDS_Boolean	enable	Allows this writer to dispatch TopicQueries. <b>Note:</b> If enable is TRUE, but you have disabled the ServiceRequest channel in the <code>enabled_builtin_channels</code> field in the <a href="#">44.3 DISCOVERY_CONFIG QosPolicy (DDS Extension) on page 703</a> , you'll get an inconsistent QoS error when creating the <i>DataWriter</i> .
struct DDS_Duration_t	publication_period	Sets the periodic interval at which samples are published.
DDS_Long	samples_per_period	Sets the maximum number of samples to publish in each <code>publication_period</code> .

This QoS policy configures the ability of a *DataWriter* to publish samples in response to a TopicQuery.

It enables the ability of a *DataWriter* to publish historical samples upon reception of a TopicQuery and how often they are published.

Since a TopicQuery selects previously written samples, the *DataWriter* must have a DurabilityQosPolicy **kind** different from DDS\_VOLATILE\_DURABILITY\_QOS. Also, the ReliabilityQosPolicy **kind** must be set to DDS\_RELIABLE\_RELIABILITY\_QOS.

A TopicQuery may select multiple samples at once. The writer will publish them periodically, independently from newly written samples. TopicQueryDispatchQosPolicy's **publication\_period**

configures the frequency of that period and its **samples\_per\_period** configures the maximum number of samples to publish each period.

If the *DataWriter* blocks during the publication of one of these samples, it will stop and try again the next period. (See [31.8 Writing Data on page 410 \(FooDataWriter::write\(\)\)](#) for the conditions that may cause the write operation to block.)

All the *DataWriters* that belong to a single *Publisher* and enable *TopicQueries* share the same event thread, but each *DataWriter* schedules separate events. To configure that thread, see the *AsynchronousPublisherQosPolicy*'s **topic\_query\_publication\_thread**.

If the *DataWriter* is dispatching more than one *TopicQuery* at the same time, the configuration of this periodic event applies to all of them. For example, if a *DataWriter* receives two *TopicQueries* around the same time, the period is 1 second, the number of samples per period is 10, the first *TopicQuery* selects five samples, and the second one selects 8, the *DataWriter* will immediately attempt to publish all five for the first *TopicQuery* and five for the second one. After one second, it will publish the remaining three samples.

## 47.24.1 Properties

This *QosPolicy* cannot be modified after the *Entity* is enabled.

There are no requirements that the publishing and subscribing sides use compatible values.

## 47.24.2 Related QosPolicies

[46.1 ASYNCHRONOUS\\_PUBLISHER QosPolicy \(DDS Extension\) on page 740](#)

## 47.24.3 Applicable Entities

- [Chapter 31 DataWriters on page 389](#)

## 47.24.4 System Resource Considerations

None.

## 47.25 TRANSFER\_MODE QosPolicy

The *TRANSFER\_MODE QosPolicy* configures the properties of a *Zero Copy DataWriter*. It contains the member listed in the following table.

Table 47.42 DDS\_TransferModeQosPolicy

Type	Field Name	Description
DDS_Boolean	enable_data_consistency_check	Enables a Zero Copy <i>DataWriter</i> to send a special sequence number as a part of its inline Qos. This sequence number is used by a Zero Copy <i>DataReader</i> to check for sample consistency in the <code>is_data_consistent()</code> operation. For more details, see <a href="#">34.1.5.1.3 Checking data consistency with Zero Copy transfer over shared memory on page 521</a> . Default: true

## 47.25.1 Properties

This QosPolicy cannot be modified after the *DataWriter* is created.

Since it is only for *DataWriters*, there are no compatibility restrictions for how it is set on the publishing and subscribing sides.

## 47.25.2 Related QosPolicies

None.

## 47.25.3 Applicable Entities

[Chapter 31 DataWriters on page 389](#)

## 47.25.4 System Resource Considerations

With `enable_data_consistency_check` set to true, a Zero Copy *DataWriter* sends an additional sequence number as part of its inline Qos with every write operation. The use of this inline QoS creates a small additional wire-payload, consuming extra bandwidth and serialization/deserialization time.

## 47.26 TRANSPORT\_PRIORITY QosPolicy

The TRANSPORT\_PRIORITY QosPolicy is optional and only partially supported on certain OSs and transports by RTI. However, its intention is to allow you to specify on a per-*DataWriter* or per-*DataReader* basis that the data sent by a *DataWriter* or *DataReader* is of a different priority.

DDS does not specify how a DDS implementation shall treat data of different priorities. It is often difficult or impossible for DDS implementations to treat data of higher priority differently than data of lower priority, especially when data is being sent (delivered to a physical transport) directly by the thread that called *DataWriter's* `write()` operation. Also, many physical network transports themselves do not have an end-user controllable level of data packet priority.

In *Connex*, for the IP-based transports (UDPv4, UDPv6, Real-Time WAN Transport, and TCP), the `value` set in the TRANSPORT\_PRIORITY QosPolicy is used in a `setsockopt` call to set the differentiated services field (DS field) bits of the IPv4 and IPv6 headers for datagrams sent by a

*DataWriter* or *DataReader*. It is platform-dependent on how and whether the **setsockopt** has an effect. On some platforms, such as Windows and Linux, external permissions must be given to the user application in order to set the TOS bits.

Note that for the IP-based transports, the transport priority **value** is not provided as is to the **setsockopt** call, but transformed according to the **transport\_priority\_mask**, **transport\_priority\_mapping\_low**, and **transport\_priority\_mapping\_high** properties (see [51.6 Setting Builtin Transport Properties with the PropertyQosPolicy on page 960](#)). In most cases, if you want the priority **value** to be exactly equal to the DS value set with the **setsockopt** call, then the only change you need to make is to set **transport\_priority\_mask** to 0xff (and keep the **transport\_priority\_mapping\_low** and **transport\_priority\_mapping\_high** defaults).

It is incorrect to assume that using the TRANSPORT\_PRIORITY QosPolicy will have any effect at all on the end-to-end delivery of data between a *DataWriter* and *DataReader*. All network elements such as switches and routers must have the capability and be enabled to actually use the TOS bits to treat higher-priority packets differently. Thus the ability to use the TRANSPORT\_PRIORITY QosPolicy must be designed and configured at a system level; just turning it on in an application may have no effect at all.

It includes the member in [Table 47.43 DDS\\_TransportPriorityQosPolicy](#). For the default and valid range, please refer to the API Reference HTML documentation.

**Table 47.43 DDS\_TransportPriorityQosPolicy**

Type	Field Name	Description
DDS_Long	value	Hint as to how to set the priority.

*Connex* will propagate the **value** set on a per-*DataWriter* or per-*DataReader* basis to the transport when the *DataWriter* publishes data. It is up to the implementation of the transport to do something with the **value**, if anything.

You can set the TRANSPORT\_PRIORITY QosPolicy on a *Topic* and use its **value** to initialize the TRANSPORT\_PRIORITY QosPolicies of *DataWriters* and *DataReaders*. The TRANSPORT\_PRIORITY QosPolicy of a *Topic* does not directly affect the operation of *Connex*, see [18.1.3 Setting Topic QosPolicies on page 250](#).

## 47.26.1 Example

Should *Connex* be configured with a transport that can use and will honor the concept of a prioritized message, then you would be able to create a *DataWriter* of a *Topic* whose DDS data samples, when published, will be sent at a higher priority than other *DataWriters* that use the same transport.

## 47.26.2 Properties

This QosPolicy cannot be modified after the entity is created.

## 47.26.3 Related QosPolicies

This QosPolicy does not interact with any other policies.

## 47.26.4 Applicable Entities

- [18.1 Topics on page 246](#)
- [Chapter 31 DataWriters on page 389](#)
- [Chapter 40 DataReaders on page 615](#)

## 47.26.5 System Resource Considerations

The use of this policy does not significantly impact the use of resources. However, if a transport is implemented to use the value set by this policy, then there may be transport-specific issues regarding the resources that the transport implementation itself uses.

## 47.27 TRANSPORT\_SELECTION QosPolicy (DDS Extension)

The TRANSPORT\_SELECTION QosPolicy allows you to select the transports that have been installed with the *DomainParticipant* to be used by the *DataWriter* or *DataReader*.

An application may be simultaneously connected to many different physical transports, e.g., Ethernet, Infiniband, shared memory, VME backplane, and wireless. By default, the middleware will use up to 16 transports to deliver data from a *DataWriter* to a *DataReader*.

This QosPolicy can be used to both limit and control which of the application's available transports may be used by a *DataWriter* to send data or by a *DataReader* to receive data.

It includes the member in [Table 47.44 DDS\\_TransportSelectionQosPolicy](#). For more information, please refer to the API Reference HTML documentation.

**Table 47.44 DDS\_TransportSelectionQosPolicy**

Type	Field Name	Description
DDS_StringSeq	enabled_transports	A sequence of aliases for the transports that may be used by the <i>DataWriter</i> or <i>DataReader</i> .

*Connex*t allows you to configure the transports that it uses to send and receive messages. A number of built-in transports, such as UDPv4 and shared memory, are available as well as custom ones that you may implement and install. Each transport will be installed in the *DomainParticipant* with one or more *aliases*.

To enable a *DataWriter* or *DataReader* to use a particular transport, add the *alias* to the **enabled\_transports** sequence of this QosPolicy. An empty sequence is a special case, and indicates that all transports installed in the *DomainParticipant* can be used by the *DataWriter* or *DataReader*.

For more information on configuring and installing transports, please see the API Reference HTML documentation (from the **Modules** page, select **RTI DDS API Reference, Pluggable Transports**).

## 47.27.1 Example

Suppose a *DomainParticipant* has both UDPv4 and shared memory transports installed. If you want a particular *DataWriter* to publish its data only over shared memory, then you should use this QosPolicy to specify that restriction.

## 47.27.2 Properties

This QosPolicy cannot be modified after the *Entity* is created.

It can be set differently for the *DataWriter* and the *DataReader*.

## 47.27.3 Related QosPolicies

- [47.28 TRANSPORT\\_UNICAST QosPolicy \(DDS Extension\)](#) below
- [48.5 TRANSPORT\\_MULTICAST QosPolicy \(DDS Extension\)](#) on page 891
- [44.7 TRANSPORT\\_BUILTIN QosPolicy \(DDS Extension\)](#) on page 725

## 47.27.4 Applicable Entities

- [Chapter 31 DataWriters](#) on page 389
- [Chapter 40 DataReaders](#) on page 615

## 47.27.5 System Resource Considerations

By restricting *DataWriters* from sending or *DataReaders* from receiving over certain transports, you may decrease the load on those transports.

## 47.28 TRANSPORT\_UNICAST QosPolicy (DDS Extension)

The TRANSPORT\_UNICAST QosPolicy allows you to specify unicast network addresses to be used by *DomainParticipant*, *DataWriters* and *DataReaders* for receiving messages.

*Connex* may send data to a variety of *Entities*, not just *DataReaders*. *DomainParticipants* receive messages to support the discovery process discussed in [Discovery Overview \(Chapter 22 on page 309\)](#). *DataWriters* may receive ACK/NACK messages to support the reliable protocol discussed in [Reliability Models for Sending Data \(Chapter 32 on page 446\)](#).

During discovery, each Entity announces to remote applications a list of (up to 16) unicast addresses to which the remote application should send data (either user-data packets or reliable protocol meta-data such as ACK/NACK and Heartbeats).

By default, the list of addresses is populated automatically with values obtained from the enabled transport plugins allowed to be used by the Entity (see the [44.7 TRANSPORT\\_BUILTIN QosPolicy \(DDS Extension\) on page 725](#) and [47.27 TRANSPORT\\_SELECTION QosPolicy \(DDS Extension\) on page 858](#)). Also, the associated ports are automatically determined (see [23.2 Inbound Ports for User Traffic on page 321](#)).

Use TRANSPORT\_UNICAST QosPolicy to manually set the receive address list for an Entity. You may optionally set a port to use a non-default receive port as well. Only the first 16 addresses will be used. *Connex*t will create a receive thread for every unique port number that it encounters (on a per transport basis).

The QosPolicy structure includes the members in [Table 47.45 DDS\\_TransportUnicastQosPolicy](#). For more information and default values, please refer to the API Reference HTML documentation.

**Table 47.45 DDS\_TransportUnicastQosPolicy**

Type	Field Name	Description
DDS_TransportUnicastSettingsSeq (see <a href="#">Table 47.46 DDS_TransportUnicastSettings_t</a> )	value	A sequence of up to 16 unicast settings that should be used by remote entities to address messages to be sent to this Entity. This is a hard limit that cannot be increased. However, this limit can be <i>decreased</i> by configuring the <i>DomainParticipant</i> property <code>dds.domain_participant.max_announced_locator_list_size</code> (whose default size is 8).

**Table 47.46 DDS\_TransportUnicastSettings\_t**

Type	Field Name	Description
DDS_StringSeq	transports	A sequence of transport aliases that specifies which transports should be used to receive unicast messages for this <i>Entity</i> .
DDS_Long	receive_port	The port that should be used in the addressing of unicast messages destined for this <i>Entity</i> . A value of 0 will cause <i>Connex</i> t to use a default port number based on <i>domain</i> and participant ids. See <a href="#">Chapter 23 Ports Used for Discovery on page 319</a> .

A message sent to a unicast address will be received by a single node on the network (as opposed to a multicast address where a single message may be received by multiple nodes). This policy sets the unicast addresses and ports that remote entities should use when sending messages to the Entity on which the TRANSPORT\_UNICAST QosPolicy is set.

Up to 16 “return” unicast addresses may be configured for an *Entity*. This is a hard limit that cannot be increased. However, this limit can be *decreased* by configuring the *DomainParticipant* **property**

**dds.domain\_participant.max\_announced\_locator\_list\_size.** Instead of specifying addresses directly, you use the **transports** field of the `DDS_TransportUnicastSetting_t` to select the transports (using their aliases) on which remote entities should send messages destined for this Entity. The addresses of the selected transports will be the “return” addresses. See the API Reference HTML documentation about configuring transports and aliases (from the **Modules** page, select **RTI Connex API Reference, Plugable Transports**).

Note, a single transport may have more than one unicast address. For example, if a node has multiple network interface cards (NICs), then the UDPv4 transport will have an address for each NIC. When using the `TRANSPORT_UNICAST` QoSPolicy to set the return addresses, a single **value** for the `DDS_TransportUnicastSettingsSeq` may provide more than the maximum number of return addresses that *Connex* accepts (8 by default, changeable to 16).

Whether or not you are able to configure the network interfaces that are allowed to be used by a transport is up to the implementation of the transport. For the built-in UDPv4 transport, you may restrict an instance of the transport to use a subset of the available network interfaces. See the API Reference HTML documentation for the built-in UDPv4 transport for more information.

For a *DomainParticipant*, this QoS policy sets the default list of addresses used by other applications to send user data for local *DataReaders*.

For a reliable *DataWriter*, if set, the other applications will use the specified list of addresses to send reliable protocol packets (ACKS/NACKS) on the behalf of reliable *DataReaders*. Otherwise, if not set, the other applications will use the addresses set by the *DomainParticipant*.

For a *DataReader*, if set, then other applications will use the specified list of addresses to send user data (and reliable protocol packets for reliable *DataReaders*). Otherwise, if not set, the other applications will use the addresses set by the *DomainParticipant*.

For a *DataReader*, if the port number specified by this QoS is the same as a port number specified by a `TRANSPORT_MULTICAST` QoS, then the transport may choose to process data received both via multicast and unicast with a single thread. Whether or not a transport must use different threads to process data received via multicast or unicast for the same port number depends on the implementation of the transport.

To use this QoSPolicy, you also need to specify a port number. A port number of 0 will cause *Connex* to automatically use a default value. As explained in [Chapter 23 Ports Used for Discovery on page 319](#), the default port number for unicast addresses is based on the domain and participant IDs. Should you choose to use a different port number, then for every unique port number used by Entities in your application, depending on the transport, *Connex* may create a thread to process messages received for that port on that transport. See [Part 11: Connex Threading Model \(on page 1180\)](#) for more about threads.

Threads are created on a per-transport basis, so if this QoSPolicy specifies multiple **transports** for a **receive\_port**, then a thread may be created for each transport for that unique port. Some transports may be able to share a single thread for different ports, others can not. Different *Entities* can share the same

port number, and thus, the same thread will process all of the data for all of the *Entities* sharing the same port number for a transport.

**Note:** If a *DataWriter* is using the [47.16 MULTI\\_CHANNEL QosPolicy \(DDS Extension\) on page 830](#), the unicast addresses specified in the TRANSPORT\_UNICAST QosPolicy are ignored by that *DataWriter*. The *DataWriter* will not publish DDS samples on those locators.

## 47.28.1 Example

You may use this QosPolicy to restrict an *Entity* from receiving data through a particular transport. For example, on a multi-NIC (network interface card) system, you may install different transports for different NICs. Then you can balance the network load between network cards by using different values for the TRANSPORT\_UNICAST QosPolicy for different *DataReaders*. Thus some *DataReaders* will receive their data from one NIC and other *DataReaders* will receive their data from another.

## 47.28.2 Properties

This QosPolicy cannot be modified after the Entity is created.

It can be set differently for the *DomainParticipant*, the *DataWriter* and the *DataReader*.

## 47.28.3 Related QosPolicies

- [47.16 MULTI\\_CHANNEL QosPolicy \(DDS Extension\) on page 830](#)
- [47.27 TRANSPORT\\_SELECTION QosPolicy \(DDS Extension\) on page 858](#)
- [48.5 TRANSPORT\\_MULTICAST QosPolicy \(DDS Extension\) on page 891](#)
- [44.7 TRANSPORT\\_BUILTIN QosPolicy \(DDS Extension\) on page 725](#)

## 47.28.4 Applicable Entities

- [16.3 DomainParticipants on page 81](#)
- [Chapter 31 DataWriters on page 389](#)
- [Chapter 40 DataReaders on page 615](#)

## 47.28.5 System Resource Considerations

Because this QosPolicy changes the transports on which messages are received for different Entities, the bandwidth used on the different transports may be affected.

Depending on the implementation of a transport, *Connex* may need to create threads to receive and process data on a unique-port-number basis. Some transports can share the same thread to process data received for different ports; others like UDPv4 must have different threads for different ports. In addition, if the same port is used for both unicast and multicast, the transport implementation will determine

whether or not the same thread can be used to process both unicast and multicast data. For UDPv4, only one thread is needed per port— independent of whether the data was received via unicast or multicast data. See [Chapter 66 Receive Threads on page 1187](#) for more information.

## 47.29 TYPESUPPORT QoSPolicy (DDS Extension)

This policy can be used to modify the code generated by *RTI Code Generator* so that the [de]serialization routines act differently depending on the information passed in via the object pointer. This policy also determines if padding bytes are set to zero during serialization.

It includes the members in [Table 47.47 DDS\\_TypeSupportQoSPolicy](#).

**Table 47.47 DDS\_TypeSupportQoSPolicy**

Type	Field Name	Description
void *	plugin_data	Value to pass into the type plug-in's serialization/deserialization function. See Note below.
DDS_CdrPaddingKind	cdr_padding_kind	<p>Determines whether or not the padding bytes will be set to zero during CDR serialization.</p> <p>For a <i>DomainParticipant</i>: Configures how padding bytes are set when serializing data for the builtin topic <i>DataWriters</i> and <i>DataReaders</i>.</p> <p>For <i>DataWriters</i> and <i>DataReaders</i>: Configures how padding bytes are set when serializing data for that entity.</p> <p>May be:</p> <ul style="list-style-type: none"> <li>• ZERO_CDR_PADDING (Padding bytes will be set to zero during CDR serialization)</li> <li>• NOT_SET_CDR_PADDING (Padding bytes will not be set to any value during CDR serialization)</li> <li>• AUTO_CDR_PADDING (For a <i>DomainParticipant</i>, the default behavior is NOT_SET_CDR_PADDING. For a <i>DataWriter</i> or <i>DataReader</i>, the behavior is to inherit the value from the <i>DomainParticipant</i>.)</li> </ul>

Note: RTI generally recommends that you treat generated source files as compiler outputs (analogous to object files) and that you do not modify them. RTI cannot support user changes to generated source files. Furthermore, such changes would make upgrading to newer versions of *Connex* more difficult, as this generated code is considered to be a part of the middleware implementation and consequently does change from version to version. *The plugin\_data field in this QoS policy should be considered a back door, only to be used after careful design consideration, testing, and consultation with your RTI representative.*

### 47.29.1 Properties

This QoS policy may be modified after the *DataWriter* or *DataReader* is enabled.

It can be set differently for the *DataWriter* and *DataReader*.

## 47.29.2 Related QoS Policies

None.

## 47.29.3 Applicable Entities

- [Chapter 31 DataWriters on page 389](#)
- [Chapter 40 DataReaders on page 615](#)
- [16.3 DomainParticipants on page 81](#)

## 47.29.4 System Resource Considerations

None.

## 47.30 USER\_DATA QoSPolicy

This QoSPolicy provides an area where your application can store additional information related to a *DomainParticipant*, *DataWriter*, or *DataReader*. This information is passed between applications during discovery (see [Discovery Overview \(Chapter 22 on page 309\)](#)) using built-in-topics (see [Accessing Discovery Information through Built-In Topics \(Chapter 28 on page 359\)](#)). How this information is used will be up to user code. *Connex*t does not do anything with the information stored as USER\_DATA except to pass it to other applications.

Use cases are usually for application-to-application identification, authentication, authorization, and encryption purposes. For example, applications can use Group or User Data to send security certificates to each other for RSA-type security.

The value of the USER\_DATA QoSPolicy is sent to remote applications when they are first discovered, as well as when the *DomainParticipant*, *DataWriter* or *DataReader*'s **set\_qos()** methods are called after changing the value of the USER\_DATA. User code can set listeners on the built-in *DataReaders* of the built-in *Topics* used by *Connex*t to propagate discovery information. Methods in the built-in topic listeners will be called whenever new *DomainParticipants*, *DataReaders*, and *DataWriters* are found. Within the user callback, you will have access to the USER\_DATA that was set for the associated *Entity*.

Currently, USER\_DATA of the associated *Entity* is only propagated with the information that declares a *DomainParticipant*, *DataWriter* or *DataReader*. Thus, you will need to access the value of USER\_DATA through **DDS\_ParticipantBuiltinTopicData**, **DDS\_PublicationBuiltinTopicData** or **DDS\_SubscriptionBuiltinTopicData** (see [Accessing Discovery Information through Built-In Topics \(Chapter 28 on page 359\)](#)).

The structure for the USER\_DATA QoSPolicy includes just one field, as seen in [Table 47.48 DDS\\_UserDataQoSPolicy](#). The field is a sequence of octets that translates to a contiguous buffer of bytes whose contents and length is set by the user. The maximum size for the data are set in the [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QoSPolicy \(DDS Extension\) on page 714](#).

**Table 47.48 DDS\_UserDataQosPolicy**

Type	Field Name	Description
DDS_OctetSeq	value	Default: empty

This policy is similar to the [46.4 GROUP\\_DATA QosPolicy on page 748](#) and [45.1 TOPIC\\_DATA QosPolicy on page 737](#) that apply to other types of Entities.

### 47.30.1 Example

One possible use of USER\_DATA is to pass some credential or certificate that your subscriber application can use to accept or reject communication with the *DataWriters* (or vice versa, where the publisher application can validate the permission of *DataReaders* to receive its data). Using the same method, an application (*DomainParticipant*) can accept or reject all connections from another application. The value of the USER\_DATA of the *DomainParticipant* is propagated in the ‘user\_data’ field of the **DDS\_ParticipantBuiltinTopicData** that is sent with the declaration of each *DomainParticipant*. Similarly, the value of the USER\_DATA of the *DataWriter* is propagated in the ‘user\_data’ field of the **DDS\_PublicationBuiltinTopicData** that is sent with the declaration of each *DataWriter*, and the value of the USER\_DATA of the *DataReader* is propagated in the ‘user\_data’ field of the **DDS\_SubscriptionBuiltinTopicData** that is sent with the declaration of each *DataReader*.

When *Connex*t discovers a *DomainParticipant/DataWriter/DataReader*, the application can be notified of the discovery of the new entity and retrieve information about the *Entity*’s QoS by reading the **DCPSParticipant**, **DCPSPublication** or **DCPSSubscription** built-in topics (see [Accessing Discovery Information through Built-In Topics \(Chapter 28 on page 359\)](#)). The user application can then examine the USER\_DATA field in the built-in *Topic* and decide whether or not the remote *Entity* should be allowed to communicate with the local *Entity*. If communication is not allowed, the application can use the *DomainParticipant*’s **ignore\_participant()**, **ignore\_publication()** or **ignore\_subscription()** operation to reject the newly discovered remote entity as one with which the application allows *Connex*t to communicate. See [28.2 Built-in DataReaders on page 360](#) for an example of how to do this.

### 47.30.2 Properties

This QosPolicy can be modified at any time. A change in the QosPolicy will cause *Connex*t to send packets containing the new USER\_DATA to all of the other applications in the DDS domain.

It can be set differently on the publishing and subscribing sides.

### 47.30.3 Related QosPolicies

- [45.1 TOPIC\\_DATA QosPolicy on page 737](#)
- [46.4 GROUP\\_DATA QosPolicy on page 748](#)

- [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QoSPolicy \(DDS Extension\) on page 714](#)

## 47.30.4 Applicable Entities

- [Chapter 31 DataWriters on page 389](#)
- [Chapter 40 DataReaders on page 615](#)
- [16.3 DomainParticipants on page 81](#)

## 47.30.5 System Resource Considerations

The maximum size of the USER\_DATA is set in the **participant\_user\_data\_max\_length**, **writer\_user\_data\_max\_length**, and **reader\_user\_data\_max\_length** fields of the [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QoSPolicy \(DDS Extension\) on page 714](#). Because *Connex* will allocated memory based on this value, you should only increase this value if you need to. If your system does not use USER\_DATA, then you can set this value to 0 to save memory. Setting the value of the USER\_DATA QoSPolicy to hold data longer than the value set in the **[participant,writer,reader]\_user\_data\_max\_length** field will result in failure and an **INCONSISTENT\_QOS\_POLICY** return code.

However, should you decide to change the maximum size of USER\_DATA, you *must* make certain that all applications in the DDS domain have changed the value of **[participant,writer,reader]\_user\_data\_max\_length** to be the same. If two applications have different limits on the size of USER\_DATA, and one application sets the USER\_DATA QoSPolicy to hold data that is greater than the maximum size set by another application, then the *DataWriters* and *DataReaders* between the two applications will *not* connect. The *DomainParticipants* may also reject connections from each other entirely. This is also true for the GROUP\_DATA ([46.4 GROUP\\_DATA QoSPolicy on page 748](#)) and TOPIC\_DATA ([45.1 TOPIC\\_DATA QoSPolicy on page 737](#)) QoS Policies.

## 47.31 WRITER\_DATA\_LIFECYCLE QoS Policy

This QoS policy controls how a *DataWriter* handles the lifecycle of the instances (keys) that the *DataWriter* is registered to manage. This QoS policy includes the members in [Table 47.49 DDS\\_Writer-DataLifecycleQoSPolicy](#).

Table 47.49 DDS\_WriterDataLifecycleQoSPolicy

Type	Field Name	Description
DDS_Boolean	autodispose_unregistered_instances	<p>Controls what happens when the <i>DataWriter</i> unregisters an instance by means of the unregister operations. This setting has no impact on the <i>DataWriter</i> deletion operation. When a <i>DataWriter</i> is deleted, and it was the last known <i>DataWriter</i> for any of the instances that it was writing, the instance will automatically be transitioned to NOT_ALIVE_NO_WRITERS by all matching <i>DataReaders</i>. No unregister messages are sent in this scenario, and therefore no dispose messages are sent, either, regardless of the value of this setting.</p> <p>RTI_TRUE: The <i>DataWriter</i> first disposes of the instance each time it unregisters from the instance. This behavior is identical to explicitly calling one of the dispose operations on the instance prior to calling the unregister operation.</p> <p><b>Note:</b> It is recommended that you keep this QoS setting at FALSE. See <a href="#">47.31.2 Autodisposing Unregistered Instances on the next page</a>.</p> <p>RTI_FALSE (default): The <i>DataWriter</i> does not dispose of the instance each time it is unregistered. The application can still call one of the dispose operations prior to unregistering the instance and dispose of the instance that way. When a <i>DataWriter</i> is deleted, no extra messages are sent. <i>DataReaders</i> will automatically unregister this <i>DataWriter</i> from all instances when they recognize that the <i>DataWriter</i> has been deleted.</p>
struct DDS_Duration_t	autopurge_unregistered_instances_delay	<p>Determines how long the <i>DataWriter</i> will maintain information regarding an instance that has been unregistered.</p> <p>By default, the <i>DataWriter</i> resources associated with an instance (e.g., the space needed to remember the Instance Key or KeyHash) are released lazily. This means the resources are only reclaimed when the space is needed for another instance because <a href="#">max_instances (47.22 RESOURCE_LIMITS QoSPolicy on page 850)</a> is exceeded. This behavior can be changed by setting <b>autopurge_unregistered_instances_delay</b> to a value other than INFINITE.</p> <p>After this time elapses, the <i>DataWriter</i> will purge all internal information regarding the instance, including historical DDS samples even if <a href="#">max_instances</a> has not been reached.</p> <p>The purging of unregistered instances can be done based on the source timestamp of the unregister sample or the time when the unregister sample was added to the <i>DataWriter</i> queue, by setting the following property to 1 or 0 respectively (default: 0): <b>dds.data_writer.history.source_timestamp_based_autopurge_instances_delay</b>. The source timestamp can differ from the time that the sample was added to the queue if a timestamp was provided along with the sample when it was written (using the <b>write_with_timestamp()</b> or <b>write_with_params()</b> operations). This is the case, for example, in <i>RTI Routing Service</i> when samples are routed with the original publisher information.</p> <p>For durable writer history, <b>autopurge_unregistered_instances_delay</b> supports only the INFINITE value.</p> <p>Default: INFINITE (except for builtin <i>DataWriters</i>, in which case 0)</p>
struct DDS_Duration_t	autopurge_disposed_instances_delay	<p>Determines the maximum duration for which the <i>DataWriter</i> will maintain information regarding an instance once it has disposed of the instance.</p> <p>By default, disposing of an instance does not make it eligible to be purged. By setting <b>autopurge_disposed_instances_delay</b> to a value other than DDS_DURATION_INFINITE, the <i>DataWriter</i> will reclaim the resources associated with an instance (including historical samples) once the time has elapsed and all matching <i>DataReaders</i> have acknowledged all the samples for this instance, including the dispose sample.</p> <p>The purging of the disposed instances can be done based on the dispose sample source timestamp or the time when the dispose sample was added to the <i>DataWriter</i> queue, by setting the following property to 1 or 0 respectively (default: 0): <b>dds.data_writer.history.source_timestamp_based_autopurge_instances_delay</b>. The source timestamp can differ from the time that the sample was added to the queue if a timestamp was provided along with the sample when it was written (using the <b>write_with_timestamp()</b> or <b>write_with_params()</b> operations). This is the case, for example, in <i>Routing Service</i> when samples are routed with the original publisher information.</p> <p><b>autopurge_disposed_instances_delay</b> is supported with durable <i>DataWriter</i> queues only for 0 and INFINITE values (finite values are not supported).</p> <p>Default: INFINITE</p>

## 47.31.1 Unregistering vs. Disposing

- Disposing an instance conveys an explicit state about an instance: for example, disposing a flight because it has landed. You can decide what dispose means for your system. See [31.14.3](#)

[Disposing Instances on page 428](#).

- Unregistering an instance can be thought of as a *DataWriter* unregistering itself from the instance, indicating that the *DataWriter* has no more information/data on the instance. An example is when radar is no longer tracking a flight. In this example, the flight is still a valid, alive instance in the system, with the same location and trajectory, but this specific radar is simply no longer tracking it. Unregistering tells *Connex* that the *DataWriter* does not intend to modify that instance anymore, allowing *Connex* to recover any resources it allocated for the instance. See [31.14.4 Unregistering Instances on page 429](#).

## 47.31.2 Autodisposing Unregistered Instances

The `autodispose_unregistered_instances` QoS setting determines whether explicit calls to an unregister operation also automatically first dispose the instance that it is being unregistered from.

It is recommended to keep the default setting of FALSE for `autodispose_unregistered_instances` and manage all instance state transitions through explicit calls to `dispose()` and `unregister_instance()` in your application. The reasons for this recommendation are as follows:

- In many cases where the ownership of a Topic is EXCLUSIVE (see the [47.17 OWNERSHIP QoS Policy on page 833](#)), *DataWriters* may want to relinquish ownership of a particular instance of the Topic to allow other *DataWriters* to send updates for the value of that instance. In this case, you may want a *DataWriter* to just unregister an instance—without disposing it (since there are other writers). Unregistering an instance implies that the *DataWriter* no longer owns that instance, but it is a stronger statement to say that instance no longer exists.
- User applications may be coded to trigger on the disposal of instances, thus the ability to unregister without disposing may be useful to properly maintain the semantic of disposal.

### 47.31.3 Properties

The `WRITER_DATA_LIFECYCLE` QoS Policy does not apply to *DataReaders*, so there is no requirement that the publishing and subscribing sides use compatible values.

This QoS policy may be modified after the *DataWriter* is enabled.

### 47.31.4 Related QoS Policies

- None.

## 48.1 DATA\_READER\_PROTOCOL QosPolicy (DDS Extension)

The `DATA_READER_PROTOCOL` QosPolicy applies only to *DataReaders* that are set up for reliable operation (see [47.21 RELIABILITY QosPolicy on page 845](#)). This policy allows the application to fine-tune the reliability protocol separately for each *DataReader*. For details of the reliable protocol used by *Connex*, see [Reliability Models for Sending Data \(Chapter 32 on page 446\)](#).

*Connex* uses a standard protocol for packet (user and meta data) exchange between applications. The `DataReaderProtocol` QosPolicy gives you control over configurable portions of the protocol, including the configuration of the reliable data delivery mechanism of the protocol on a per *DataReader* basis.

These configuration parameters control timing and timeouts, and give you the ability to trade off between speed of data loss detection and repair, versus network and CPU bandwidth used to maintain reliability.

It is important to tune the reliability protocol on a per *DataReader* basis to meet the requirements of the end-user application so that data can be sent between *DataWriters* and *DataReaders* in an efficient and optimal manner in the presence of data loss.

You can also use this QosPolicy to control how DDS responds to "slow" reliable *DataReaders* or ones that disconnect or are otherwise lost.

See the [47.21 RELIABILITY QosPolicy on page 845](#) for more information on the per-*DataReader/DataWriter* reliability configuration. The [47.12 HISTORY QosPolicy on page 818](#) and [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#) also play an important role in the DDS reliability protocol.

This policy includes the members presented in [Table 48.1 DDS\\_DataReaderProtocolQosPolicy](#) and [Table 48.2 DDS\\_RtpsReliableReaderProtocol\\_t](#). For defaults and valid ranges, please refer to the API Reference HTML documentation.

When setting the fields in this policy, the following rule applies. If this is false, *Connex* returns `DDS_RETCODE_INCONSISTENT_POLICY` when setting the QoS:

**`max_heartbeat_response_delay >= min_heartbeat_response_delay`**

Table 48.1 DDS\_DataReaderProtocolQoSPolicy

Type	Field Name	Description
DDS_GUID_t	virtual_guid	<p>The virtual GUID (Global Unique Identifier) is used to uniquely identify the same <i>DataReader</i> across multiple incarnations. In other words, this value allows <i>Connex</i>t to remember information about a <i>DataReader</i> that may be deleted and then re-created.</p> <p>This value is used to provide durable reader state.</p> <p>For more information, see <a href="#">21.2 Durability and Persistence Based on Virtual GUIDs on page 293</a>.</p> <p>By default, <i>Connex</i>t will assign a virtual GUID automatically. If you want to restore the <i>DataReader</i>'s state after a restart, you can get the <i>DataReader</i>'s virtual GUID using its <code>get_qos()</code> operation, then set the virtual GUID of the restarted <i>DataReader</i> to the same value.</p>
DDS_UnsignedLong	rtps_object_id	<p>Determines the <i>DataReader</i>'s RTPS object ID, according to the DDS-RTPS Interoperability Wire Protocol.</p> <p>Only the last 3 bytes are used; the most significant byte is ignored.</p> <p>The <code>rtps_host_id</code>, <code>rtps_app_id</code>, <code>rtps_instance_id</code> in the <a href="#">44.9 WIRE_PROTOCOL QoSPolicy (DDS Extension) on page 730</a>, together with the 3 least significant bytes in <code>rtps_object_id</code>, and another byte assigned by <i>Connex</i>t to identify the entity type, forms the BuiltinTopicKey in SubscriptionBuiltinTopicData.</p>
DDS_Boolean	expects_inline_qos	<p>Specifies whether this <i>DataReader</i> expects inline QoS with every sample.</p> <p><i>Connex</i>t <i>DataWriters</i> do not match with <i>DataReaders</i> that set this field to TRUE (because <i>Connex</i>t <i>DataWriters</i> do not support sending inline QoS), but here is how this field is meant to be used:</p> <p><i>DataReaders</i> usually rely on the discovery process to propagate QoS changes for matched <i>DataWriters</i>. Another way to get QoS information is to have it sent inline with a DDS sample.</p> <p>With <i>Connex</i>t, <i>DataWriters</i> and <i>DataReaders</i> cache discovery information, so sending inline QoS is typically unnecessary. The use of inline QoS is only needed for stateless implementations of DDS in which <i>DataReaders</i> do not cache Discovery information.</p> <p>The complete set of QoS that a <i>DataWriter</i> may send inline is specified by the Real-Time Publish-Subscribe (RTPS) Wire Interoperability Protocol.</p> <p>Note: The use of inline QoS creates an additional wire-payload, consuming extra bandwidth and serialization/deserialization time.</p>
DDS_Boolean	disable_positive_acks	<p>Determines whether the <i>DataReader</i> sends positive acknowledgements (ACKs) to matching <i>DataWriters</i>.</p> <p>When TRUE, the matching <i>DataWriter</i> will keep DDS samples in its queue for this <i>DataReader</i> for a minimum keep duration (see <a href="#">47.5.3 Disabling Positive Acknowledgements on page 795</a>).</p> <p>When strict-reliability is not required and NACK-based reliability is sufficient, setting this field reduces overhead network traffic.</p>

Table 48.1 DDS\_DataReaderProtocolQosPolicy

Type	Field Name	Description
DDS_Boolean	propagate_dispose_of_unregistered_instances	<p>Indicates whether or not an instance can move to the DDS_NOT_ALIVE_DISPOSED_INSTANCE_STATE state without being in the DDS_ALIVE_INSTANCE_STATE state. See <a href="#">19.1 Instance States on page 258</a> for more information about this transition.</p> <p>When set to TRUE, the <i>DataReader</i> will receive dispose notifications even if the instance is not alive.</p> <p>This field only applies to keyed <i>DataReaders</i>.</p> <p>To make sure the key is available to the <i>FooDataReader</i>'s <code>get_key_value()</code> operation, use this option in combination with setting the <i>DataWriter</i>'s <code>serialize_key_with_dispose</code> field (in the <a href="#">47.5 DATA_WRITER_PROTOCOL QosPolicy (DDS Extension) on page 788</a>) to TRUE.</p> <p>See <a href="#">47.5.5 Propagating Serialized Keys with Disposed-Instance Notifications on page 796</a>.</p>
DDS_Boolean	propagate_unregister_of_disposed_instances	<p>Indicates whether or not an instance can move to the DDS_NOT_ALIVE_NO_WRITERS_INSTANCE_STATE state directly from the DDS_NOT_ALIVE_DISPOSED_INSTANCE_STATE. See <a href="#">19.1 Instance States on page 258</a> for more information about this transition.</p> <p>When set to TRUE, the <i>DataReader</i> will receive unregister notifications even if the instance is already disposed.</p> <p>This field only applies to keyed <i>DataReaders</i>.</p>
DDS_RtpsReliableReaderProtocol_t	rtps_reliable_reader	See <a href="#">Table 48.2 DDS_RtpsReliableReaderProtocol_t</a>

Table 48.2 DDS\_RtpsReliableReaderProtocol\_t

Type	Field Name	Description
DDS_Duration_t	min_heartbeat_response_delay	Minimum delay between when the <i>DataReader</i> receives a heartbeat and when it sends an ACK/NACK.
DDS_Duration_t	max_heartbeat_response_delay	Maximum delay between when the <i>DataReader</i> receives a heartbeat and when it sends an ACK/NACK. Increasing this value helps prevent NACK storms, but increases latency.
DDS_Duration_t	heartbeat_suppression_duration	<p>How long additionally received heartbeats are suppressed.</p> <p>When a reliable <i>DataReader</i> receives consecutive heartbeats within a short duration, this may trigger redundant NACKs. To prevent the <i>DataReader</i> from sending redundant NACKs, the <i>DataReader</i> may ignore the latter heartbeat(s) for this amount of time.</p> <p>See <a href="#">32.4.4.1 How Often Heartbeats are Resent (heartbeat_period) on page 462</a>.</p>
DDS_Duration_t	nack_period	Rate at which to send negative acknowledgements to new <i>DataWriters</i> . See <a href="#">48.1.3 Example on page 875</a> .
DDS_Long	receive_window_size	The number of received out-of-order DDS samples a reader can keep at a time. See <a href="#">48.1.1 Receive Window Size on the next page</a>

Table 48.2 DDS\_RtpsReliableReaderProtocol\_t

Type	Field Name	Description
DDS_Duration_t	round_trip_time	The duration from sending a NACK to receiving a repair of a DDS sample. See <a href="#">48.1.2 Round-Trip Time For Filtering Redundant NACKs on the next page</a>
DDS_Duration_t	app_ack_period	The period at which application-level acknowledgment messages are sent. A <i>DataReader</i> sends application-level acknowledgment messages to a <i>DataWriter</i> at this periodic rate, and will continue sending until it receives a message from the <i>DataWriter</i> that it has received and processed the acknowledgment.
DDS_Duration_t	min_app_ack_response_keep_duration	Minimum duration for which application-level acknowledgment response data is kept. The user-specified response data of an explicit application-level acknowledgment (called by <i>DataReader</i> 's <b>acknowledge_sample()</b> or <b>acknowledge_all()</b> operations) is cached by the <i>DataReader</i> for the purpose of reliably resending the data with the acknowledgment message. After this duration has passed from the time of the first acknowledgment, the response data is dropped from the cache and will not be resent with future acknowledgments for the corresponding DDS sample(s).
DDS_Long	samples_per_app_ack	The minimum number of DDS samples acknowledged by one application-level acknowledgment message. This setting applies only when the <a href="#">47.21 RELIABILITY QosPolicy on page 845 acknowledge_kind</a> is set to APPLICATION_EXPLICIT or APPLICATION_AUTO. A <i>DataReader</i> will immediately send an application-level acknowledgment message when it has at least this many DDS samples that have been acknowledged. It will not send an acknowledgment message until it has at least this many DDS samples pending acknowledgment. For example, calling the <i>DataReader</i> 's <b>acknowledge_sample()</b> this many times consecutively will trigger the sending of an acknowledgment message. Calling the <i>DataReader</i> 's <b>acknowledge_all()</b> may trigger the sending of an acknowledgment message, if at least this many DDS samples are being acknowledged at once. See <a href="#">41.4 Acknowledging DDS Samples on page 674</a> . This is independent of the DDS_RtpsReliableReaderProtocol_t's <b>app_ack_period</b> , where a <i>DataReader</i> will send acknowledgment messages at the periodic rate regardless. When this is set to DDS_LENGTH_UNLIMITED, acknowledgment messages are sent only periodically, at the rate set by DDS_RtpsReliableReaderProtocol_t's <b>app_ack_period</b> .

## 48.1.1 Receive Window Size

A reliable *DataReader* presents DDS samples it receives to the user in-order. If it receives DDS samples out-of-order, it stores them internally until the other missing DDS samples are received. For example, if the *DataWriter* sends DDS samples 1 and 2, if the *DataReader* receives 2 first, it will wait until it receives 1 before passing the DDS samples to the user.

The number of out-of-order DDS samples that a *DataReader* can keep is set by the **receive\_window\_size**. A larger window allows more out-of-order DDS samples to be kept. When the window is full, any subsequent out-of-order DDS samples received will be rejected, and such rejections would necessitate NACK repairs that would degrade throughput. So, in network environments where out-of-order samples are more probable or where NACK repairs are costly, this window likely should be increased.

By default, the window is set to 256, which is the maximum number of DDS samples a single NACK submessage can request.

Samples rejected for exceeding the `receive_window_size` are counted in `out_of_range_rejected_sample_count` in the [40.7.3 DATA\\_READER\\_PROTOCOL\\_STATUS on page 630](#), but not included in the [40.7.8 SAMPLE\\_REJECTED Status on page 640](#).

## 48.1.2 Round-Trip Time For Filtering Redundant NACKs

When a *DataReader* requests for a DDS sample to be resent, there is a delay from when the NACK is sent, to when it receives the resent DDS sample. During that delay, the *DataReader* may receive HEARTBEATs that normally would trigger another NACK for the same DDS sample. Such redundant repairs waste bandwidth and degrade throughput.

The `round_trip_time` is a user-configured estimate of the delay between sending a NACK to receiving a repair. A *DataReader* keeps track of when a DDS sample has been NACK'd, and will prevent subsequent NACKs from redundantly requesting for the same DDS sample, until the round trip time has passed.

Note that the default value of 0 seconds means that the *DataReader* does not filter for redundant NACKs.

### 48.1.3 Example

For many applications, changing these values will not be necessary. However, the more nodes that your distributed application uses, and the greater the amount of network traffic it generates, the more likely it is that you will want to consider experimenting with these values.

When a reliable *DataReader* receives a heartbeat from a *DataWriter*, it will send an ACK/NACK packet back to the *DataWriter*. Instead of sending the packet out immediately, the *DataReader* can choose to send it after a delay. This policy sets the minimum and maximum time to delay; the actual delay will be a random value in between. (For more on heartbeats and ACK/NACK messages, see [Discovery Overview \(Chapter 22 on page 309\)](#).)

Why is a delay useful? For *DataWriters* that have multiple reliable *DataReaders*, an efficient way of heartbeating all of the *DataReaders* is to send a single heartbeat via multicast. In that case, all of the *DataReaders* will receive the heartbeat (approximately) simultaneously. If all *DataReaders* immediately respond with a ACK/NACK packet, the network may be flooded. While the size of a ACK/NACK packet is relatively small, as the number of *DataReaders* increases, the chance of packet collision also increases. All of these conditions may lead to dropped packets which forces the *DataWriter* to send out additional heartbeats that cause more simultaneous heartbeats to be sent, ultimately resulting a network packet storm.

By forcing each *DataReader* to wait for a random amount of time, bounded by the minimum and maximum values in this policy, before sending an ACK/NACK response to a heartbeat, the use of the network is spread out over a period of time, decreasing the peak bandwidth required as well as the likelihood of dropped packets due to collisions. This can increase the overall performance of the reliable connection while avoiding a network storm.

When a reliable *DataReader* first matches a reliable *DataWriter*, the *DataReader* sends periodic NACK messages at the specified period to pull historical data from the *DataWriter*. The *DataReader* will stop sending periodic NACKs when it has received all historical data available at the time that it matched the *DataWriter*. The *DataReader* ensures that at least one NACK is sent per period; for example, if, within a NACK period, the *DataReader* responds to a HEARTBEAT message with a NACK, then the *DataReader* will not send another periodic NACK.

#### 48.1.4 Properties

This QosPolicy cannot be modified after the *DataReader* is created.

It only applies to *DataReaders*, so there are no restrictions for setting it compatibly with respect to *DataWriters*.

#### 48.1.5 Related QosPolicies

- [47.5 DATA\\_WRITER\\_PROTOCOL QosPolicy \(DDS Extension\) on page 788](#)
- [47.21 RELIABILITY QosPolicy on page 845](#)

#### 48.1.6 Applicable DDS Entities

- [Chapter 40 DataReaders on page 615](#)

#### 48.1.7 System Resource Considerations

Changing the values in this policy requires making tradeoffs between minimizing latency (decreasing **min\_heartbeat\_response\_delay**), maximizing determinism (decreasing the difference between **min\_heartbeat\_response\_delay** and **max\_heartbeat\_response\_delay**), and minimizing network collisions/spreading out the ACK/NACK packets across a time interval (increasing the difference between **min\_heartbeat\_response\_delay** and **max\_heartbeat\_response\_delay** and/or shifting their values between different *DataReaders*).

If the values are poorly chosen with respect to the characteristics and requirements of a given application, the latency and/or throughput of the application may suffer.

### 48.2 DATA\_READER\_RESOURCE\_LIMITS QosPolicy (DDS Extension)

The DATA\_READER\_RESOURCE\_LIMITS QosPolicy extends your control over the memory allocated by *Connex* for *DataReaders* beyond what is offered by the [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#). RESOURCE\_LIMITS controls memory allocation with respect to the *DataReader* itself: the number of DDS samples that it can store in the receive queue and the number of instances that it can manage simultaneously. DATA\_READER\_RESOURCE\_LIMITS controls memory allocation on a per matched-*DataWriter* basis. The two are orthogonal.

This policy includes the members in [Table 48.3 DDS\\_DataReaderResourceLimitsQosPolicy](#). For defaults and valid ranges, please refer to the API Reference HTML documentation.

**Table 48.3 DDS\_DataReaderResourceLimitsQosPolicy**

Type	Field Name	Description
DDS_ Long	max_remote_writers	Maximum number of <i>DataWriters</i> from which a <i>DataReader</i> may receive DDS data samples, among all instances. For unkeyed <i>Topics</i> : <b>max_remote_writers</b> must = <b>max_remote_writers_per_instance</b>
	max_remote_writers_per_instance	Maximum number of <i>DataWriters</i> from which a <i>DataReader</i> may receive DDS data samples for a single instance. For unkeyed <i>Topics</i> : <b>max_remote_writers</b> must = <b>max_remote_writers_per_instance</b>
	max_samples_per_remote_writer	Maximum number of DDS samples received out-of-order that a <i>DataReader</i> can store from a single reliable <i>DataWriter</i> . <b>max_samples_per_remote_writer</b> must be <= <b>RESOURCE_LIMITS::max_samples</b>
	max_infos	Maximum number of DDS_SampleInfo structures that a <i>DataReader</i> can allocate. <b>max_infos</b> must be >= <b>RESOURCE_LIMITS::max_samples</b>
	initial_remote_writers	Initial number of <i>DataWriters</i> from which a <i>DataReader</i> may receive DDS data samples, including all instances. For unkeyed <i>Topics</i> : <b>initial_remote_writers</b> must = <b>initial_remote_writers_per_instance</b>
	initial_remote_writers_per_instance	Initial number of <i>DataWriters</i> from which a <i>DataReader</i> may receive DDS data samples for a single instance. For unkeyed <i>Topics</i> : <b>initial_remote_writers</b> must = <b>initial_remote_writers_per_instance</b>
	initial_infos	Initial number of DDS_SampleInfo structures that a <i>DataReader</i> will allocate.
	initial_outstanding_reads	Initial number of times in which memory can be concurrently loaned via read/take calls without being returned with <b>return_loan()</b> .
	max_outstanding_reads	Maximum number of times in which memory can be concurrently loaned via read/take calls without being returned with <b>return_loan()</b> .
	max_samples_per_read	Maximum number of DDS samples that can be read/taken on a <i>DataReader</i> .
DDS_ Boolean	disable_fragmentation_support	Determines whether the <i>DataReader</i> can receive fragmented DDS samples. When fragmentation support is not needed, disabling fragmentation support will save some memory resources.

Table 48.3 DDS\_DataReaderResourceLimitsQoSPolicy

Type	Field Name	Description
DDS_ Long	max_frag- mented_ samples	<p>The maximum number of DDS samples for which the <i>DataReader</i> may store fragments at a given point in time.</p> <p>At any given time, a <i>DataReader</i> may store fragments for up to <b>max_fragmented_samples</b> DDS samples while waiting for the remaining fragments. These DDS samples need not have consecutive sequence numbers and may have been sent by different <i>DataWriters</i>. Once all fragments of a DDS sample have been received, the DDS sample is treated as a regular DDS sample and becomes subject to standard QoS settings, such as max_ samples. <i>Connex</i> will drop fragments if the max_fragmented_samples limit has been reached.</p> <p>For best-effort communication, <i>Connex</i> will accept a fragment for a new DDS sample, but drop the oldest fragmented DDS sample from the same remote writer.</p> <p>For reliable communication, <i>Connex</i> will drop fragments for any new DDS samples until all fragments for at least one older DDS sample from that writer have been received.</p> <p>Only applies if <b>disable_fragmentation_support</b> is FALSE.</p>
	initial_frag- mented_ samples	<p>The initial number of DDS samples for which a <i>DataReader</i> may store fragments.</p> <p>Only applies if <b>disable_fragmentation_support</b> is FALSE.</p>
	max_frag- mented_ samples_per_re- mote_ writer	<p>The maximum number of DDS samples per remote writer for which a <i>DataReader</i> may store fragments. This is a logical limit, so a single remote writer cannot consume all available resources.</p> <p>Only applies if <b>disable_fragmentation_support</b> is FALSE.</p>
	max_fragments_ per_ sample	<p>Maximum number of fragments for a single DDS sample.</p> <p>Only applies if <b>disable_fragmentation_support</b> is FALSE.</p>
DDS_ Boolean	dynamically_al- locate_ fragmented_ samples	<p>By default, the middleware does not allocate memory upfront, but instead allocates memory from the heap upon receiving the first fragment of a new sample. The amount of memory allocated equals the amount of memory needed to store all fragments in the sample. Once all fragments of a sample have been received, the sample is deserialized and stored in the regular receive queue. At that time, the dynamically allocated memory is freed again.</p> <p>This QoS setting is useful for large, but variable-sized data types where upfront memory allocation for multiple samples based on the maximum possible sample size may be expensive. The main disadvantage of not pre-allocating memory is that one can no longer guarantee the middleware will have sufficient resources at run-time.</p> <p>If dynamically_allocate_fragmented_samples is FALSE, the middleware will allocate memory up-front for storing fragments for up to initial_fragmented_samples samples. This memory may grow up to max_fragmented_samples if needed.</p> <p>Only applies if disable_fragmentation_support is FALSE.</p>
DDS_ Long	max_total_in- stances	<p>Maximum number of instances (attached + detached instances) for which a <i>DataReader</i> will keep state. Only applicable if <b>keep_minimum_state_for_instances</b> is TRUE.</p> <p>See <a href="#">48.2.1 max_total_instances and max_instances on page 881</a></p>

Table 48.3 DDS\_DataReaderResourceLimitsQosPolicy

Type	Field Name	Description
DDS_DataReaderResourceLimitsInstanceReplacementSettings	instance_replacement	Sets the kinds of instances allowed to be replaced for each instance state when a <i>DataReader</i> reaches <b>max_instances</b> in the <a href="#">47.22 RESOURCE_LIMITS QosPolicy</a> on page 850. See <a href="#">48.2.3 Configuring DataReader Instance Replacement</a> on page 882.
DDS_Long	max_remote_virtual_writers	The maximum number of virtual writers (identified by a virtual GUID) from which a <i>DataReader</i> may read, including all instances. When the <i>Subscriber's</i> <b>access_scope</b> is GROUP, this value determines the maximum number of <i>DataWriter</i> groups supported by the <i>Subscriber</i> . Since the <i>Subscriber</i> may contain more than one <i>DataReader</i> , only the setting of the first applies.
DDS_Long	initial_remote_virtual_writers	The initial number of virtual writers from which a <i>DataReader</i> may read, including all instances.
DDS_Long	max_remote_virtual_writers_per_instance	Maximum number of virtual remote writers that can be associated with an instance. For unkeyed types, this value is ignored. The features of Durable Reader State and MultiChannel <i>DataWriters</i> , as well as <i>Persistence Service</i> , require <i>Connex</i> to keep some internal state per virtual writer and instance that is used to filter duplicate DDS samples. These duplicate DDS samples could be coming from different <i>DataWriter</i> channels or from multiple executions of <i>Persistence Service</i> . Once an association between a remote virtual writer and an instance is established, it is permanent—it will not disappear even if the physical writer incarnating the virtual writer is destroyed. If <b>max_remote_virtual_writers_per_instance</b> is exceeded for an instance, <i>Connex</i> will not associate this instance with new virtual writers. Duplicate DDS samples coming from these virtual writers will not be filtered on the reader. If you are not using Durable Reader State, MultiChannel <i>DataWriters</i> or <i>Persistence Service</i> , you can set this property to 1 to optimize resources. For additional information about the virtual writers see <a href="#">Mechanisms for Achieving Information Durability and Persistence (Chapter 21 on page 288)</a> .
DDS_Long	initial_remote_virtual_writers_per_instance	Initial number of virtual remote writers per instance. For unkeyed types, this value is ignored.
DDS_Long	max_remote_writers_per_sample	Maximum number of remote writers that are allowed to write the same DDS sample. One scenario in which two <i>DataWriters</i> may write the same DDS sample is when using <i>Persistence Service</i> . The <i>DataReader</i> may receive the same DDS sample from the original <i>DataWriter</i> and from an <i>Persistence Service</i> <i>DataWriter</i> .
DDS_Long	max_query_condition_filters	This value determines the maximum number of unique query condition content filters that a reader may create. Each query condition content filter is comprised of both its <b>query_expression</b> and <b>query_parameters</b> . Two query conditions that have the same <b>query_expression</b> will require unique query condition filters if their <b>query_parameters</b> differ. Query conditions that differ only in their state masks will share the same query condition filter.

Table 48.3 DDS\_DataReaderResourceLimitsQosPolicy

Type	Field Name	Description
DDS_Long	max_app_ack_response_length	The maximum length of response data in an application-level acknowledgment. When set to zero, no response data is sent with application-level acknowledgments.
DDS_Boolean	keep_minimum_state_for_instances	Determines whether the <i>DataReader</i> keeps a minimum instance state for up to <b>max_total_instances</b> . The minimum state is useful for filtering samples in certain scenarios. See <a href="#">48.2.1 max_total_instances and max_instances on the next page</a>
DDS_Long	initial_topic_queries	The initial number of TopicQueries allocated by a <i>DataReader</i> .
DDS_Long	max_topic_queries	The maximum number of active TopicQueries that a <i>DataReader</i> can create. Once this limit is reached, a <i>DataReader</i> can create more TopicQueries only if it deletes some of the previously created ones.
DDS_AllocationSettings_t	shmem_ref_transfer_mode_attached_segment_allocation	Configures the allocation resource used to attach to different shared memory segments if you are using Zero Copy transfer over shared memory. See <a href="#">34.1.5 Zero Copy Transfer Over Shared Memory on page 516</a> .

*DataReaders* must allocate internal structures to handle: the maximum number of *DataWriters* that may connect to it; whether or not a *DataReader* handles data fragmentation and how many data fragments that it may handle (for *DDS* data samples larger than the MTU of the underlying network transport); how many simultaneous outstanding loans of internal memory holding *DDS* data samples can be provided to user code; as well as others.

Most of these internal structures start at an initial size and, by default, will grow as needed by dynamically allocating additional memory. You may set fixed, maximum sizes for these internal structures if you want to bound the amount of memory that can be used by a *DataReader*. Setting the initial size to the maximum size will prevent *Connex*t from dynamically allocating any memory after the *DataReader* is created.

This policy also controls how the allocated internal data structure may be used. For example, *DataReaders* need data structures to keep track of all of the *DataWriters* that may be sending it *DDS* data samples. The total number of *DataWriters* that it can keep track of is set by the **initial\_remote\_writers** and **max\_remote\_writers** values. For keyed Topics, **initial\_remote\_writers\_per\_instance** and **max\_remote\_writers\_per\_instance** control the number of *DataWriters* allowed by the *DataReader* to modify the value of a single instance.

By setting the max value to be less than **max\_remote\_writers**, you can prevent instances with many *DataWriters* from using up the resources and starving other instances. Once the resources for keeping track of *DataWriters* are used up, the *DataReader* will not be able to accept “connections” from new *DataWriters*. The *DataReader* will not be able to receive data from new matching *DataWriters* which would be ignored.

In the reliable protocol used by *Connex* to support a RELIABLE setting for the [47.21 RELIABILITY QoSPolicy on page 845](#), the *DataReader* must temporarily store DDS data samples that have been received out-of-order from a reliable *DataWriter*. The storage of out-of-order DDS samples is allocated from the *DataReader*'s receive queue and shared among all reliable *DataWriters*. The parameter **max\_samples\_per\_remote\_writer** controls the maximum number of out-of-order data DDS samples that the *DataReader* is allowed to store for a single *DataWriter*. This value must be less than the **max\_samples** value set in the [47.22 RESOURCE\\_LIMITS QoSPolicy on page 850](#).

**max\_samples\_per\_remote\_writer** allows *Connex* to share the limited resources of the *DataReader* equitably so that a single *DataWriter* is unable to use up all of the storage of the *DataReader* while missing DDS data samples are being resent.

When setting the values of the members, the following rules apply:

- **max\_remote\_writers** >= **initial\_remote\_writers**
- **max\_remote\_writers\_per\_instance** >= **initial\_remote\_writers\_per\_instance**  
**max\_remote\_writers\_per\_instance** <= **max\_remote\_writers**
- **max\_infos** >= **initial\_infos**  
**max\_infos** >= RESOURCE\_LIMITS::max\_samples
- **max\_outstanding\_reads** >= **initial\_outstanding\_reads**
- **max\_remote\_writers** >= **max\_remote\_writers\_per\_instance**
- **max\_samples\_per\_remote\_writer** <= RESOURCE\_LIMITS::max\_samples

If any of the above are false, *Connex* returns the error code **DDS\_RETCODE\_INCONSISTENT\_POLICY** when setting the *DataReader*'s QoS.

## 48.2.1 max\_total\_instances and max\_instances

The features [21.4 Durable Reader State on page 299](#), [Multi-Channel DataWriters for High-Performance Filtering \(Chapter 36 on page 576\)](#), and [Persistence Service \( Part 12: RTI Persistence Service on page 1205\)](#) require *Connex* to keep some minimum internal state even for instances without *DataWriters* or DDS samples in the *DataReader*'s queue or that have been purged due to a dispose. Instances for which only this minimum state is kept are called *detached* instances. The additional state is used to filter duplicate DDS samples that could be coming from different *DataWriter* channels or from multiple executions of *Persistence Service*. The total maximum number of instances that will be managed by the middleware, attached plus detached instances, is determined by **max\_total\_instances**. This additional state will only be kept for up to **max\_total\_instances** if **keep\_minimum\_state\_for\_instances** is TRUE, otherwise the additional state will not be kept for any instances. The minimum state includes information such as the source timestamp of the last sample received by the instance and the last sequence number received from a virtual GUID. See also [40.8.7 Active State and Minimum State on page 649](#).

## 48.2.2 keep\_minimum\_state\_for\_instances

There are important implications of the minimum state setting.

When a *DataReader* is exposed to an unbounded number of instances over its lifetime (for example, if the key for an instance is a UUID and the application cycles through unlimited numbers of such UUIDs over time) and the *DataReader* does keep its minimum state, the set of minimum state data will grow with the total number of instances (unique keys) the *DataReader* has been exposed to until **max\_total\_instances** is reached.

**max\_total\_instances** by default gets its value from **max\_instances**. If **max\_instances** is set to its default value, which is unbounded, the *DataReader*'s memory will grow slowly but without bound until the *DataReader* itself is deleted. As a rule of thumb, when instances are used only once in a system and are never used again after being disposed or unregistered, set **max\_instances** and **max\_total\_instances** to finite values or bound the lifetime of the *DataReader* (see [15.1 Creating and Deleting DDS Entities on page 33](#)). If neither of these options is practical, it may help to set **keep\_minimum\_state\_for\_instances** to FALSE.

If a *DataReader* does not retain this minimum state, there may be correctness implications if the *DataReader* is exposed to an instance again after it has been removed from the *DataReader* cache. For example, because the last source timestamp is not preserved, eventual consistency cannot be assured (even if destination order is by source timestamp). Samples that had already been received by the *DataReader* may be re-delivered and provided to the application again as if for the first time (especially when using redundant *Routing Service* routes, *Persistence Service*, or *Collaborative DataWriters*). As a rule of thumb, when instances have complex lifecycles (especially involving multiple *DataWriters* modifying the instance), in which an instance can become not alive and later come alive again, set **keep\_minimum\_state\_for\_instances** to TRUE.

## 48.2.3 Configuring DataReader Instance Replacement

When the **max\_instances** limit in the [47.22 RESOURCE\\_LIMITS QoS Policy on page 850](#) is reached, a *DataReader* will try to make space for a new instance by replacing an existing instance according to the instance replacement kind set in **instance\_replacement** in the [48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QoS Policy \(DDS Extension\) on page 876](#). If it cannot make space for the new instance, the sample for the new instance will be lost with the reason **LOST\_BY\_INSTANCES\_LIMIT** (see [40.7.7 SAMPLE\\_LOST Status on page 636](#)).

The **instance\_replacement** field is useful for managing large volumes of instances that come and go. It is important to be able to set an upper limit on the resources that will be used by an application to avoid running into decreased performance and potentially running out of system resources. The **instance\_replacement** QoS setting allows you to set an upper bound on the resources that will be used for instances. It allows *DataReaders* to make room for new instances by replacing older ones. For example, a hospital may have 100 beds. Many patients (instances) come and go, so at any given time you only need resources for 100 instances, but over time you will see an unbounded number of instances. An instance replacement policy can help manage this flow.

For each instance state (see [40.8.1 Instance States on page 644](#)), you can set the following removal kinds:

- The `alive_instance_removal` kind sets a removal policy for ALIVE instances (default: `DDS_NO_INSTANCE_REMOVAL`).
- The `disposed_instance_removal` kind sets a removal policy for NOT\_ALIVE\_DISPOSED instances (default: `DDS_EMPTY_INSTANCE_REMOVAL`).
- The `no_writers_instance_removal` kind sets a removal policy for NOT\_ALIVE\_NO\_WRITERS instances (default: `DDS_EMPTY_INSTANCE_REMOVAL`).

For each instance state, you can choose among the following replacement kinds:

- `DDS_NO_INSTANCE_REMOVAL`: Instances in the associated state cannot be replaced.
- `DDS_EMPTY_INSTANCE_REMOVAL`: Instances in the associated state can be replaced only if they are empty (all samples have been taken or removed from the *DataReader* queue due to QoS settings such as, but not limited to, the [47.14 LIFESPAN QoS Policy on page 824](#) or sample purging due to the [48.3 READER\\_DATA\\_LIFECYCLE QoS Policy on page 885](#)), and there are no outstanding loans on any of the instance's samples.
- `DDS_FULLY_PROCESSED_INSTANCE_REMOVAL`: Instances in the associated state can be replaced only if every sample has been processed by the application. A sample is considered processed by the application based on the Reliability kind:
  - If the Reliability kind is RELIABLE, a sample is considered processed by the application based on the `ApplicationAcknowledgementKind` (see [31.12.1 Application Acknowledgment Kinds on page 418](#)):
    - `PROTOCOL_ACKNOWLEDGMENT_MODE` or `APPLICATION_AUTO_ACKNOWLEDGEMENT_MODE`: The sample is considered processed when it has been read or taken by the application and `return_loan` has been called.
    - `APPLICATION_EXPLICIT_ACKNOWLEDGMENT_MODE`: The sample is considered processed when the subscribing application has explicitly acknowledged the sample by calling either the *DataReader's* `acknowledge_sample()` or `acknowledge_all()` operations, the `AppAckConf` message has been received, and the application has called `return_loan`.
  - If the Reliability kind is BEST\_EFFORT, a sample is considered processed by the application when all samples have been read or taken by the application and `return_loan` has been called.

- **DDS\_ANY\_INSTANCE\_REMOVAL**: Instances in the associated state can be replaced regardless of whether the subscribing application has processed all of the samples. Samples that have not been processed will be dropped and accounted for by the **total\_samples\_dropped\_by\_instance\_replacement** statistic in the [40.7.2 DATA\\_READER\\_CACHE\\_STATUS on page 627](#).

For all kinds, instance replacement starts with the *least-recently-updated* (LRU) instance that matches the allowed criteria. For example, if **alive\_instance\_removal** is set to **DDS\_EMPTY\_INSTANCE\_REMOVAL**: when the **max\_instances** limit is reached, the least-recently-updated, empty, **ALIVE** instance will be replaced to make room for the new instance. An instance is considered updated when a valid sample or dispose sample for the instance is received and accepted by the *DataReader*. An instance is not considered updated in the following cases:

- When using **EXCLUSIVE\_OWNERSHIP**, when samples that are received from *DataWriters* that do not own the instance. Only the owner of an instance can update the instance.
- A sample that is filtered out due to content filtering does not count as updating the instance.
- Unregister messages do not count as an update to the instance because the unregister message conveys information about the *DataWriter* (that it is finished updating the instance), as opposed to any change to the instance itself.

There is no preference among the instance states as far as which instance is replaced first; instance replacement relies only on the LRU. For example, imagine if *Connex* were to prefer disposed\_instance\_removal over alive\_instance\_removal. It doesn't, but if it did, the application might never see disposed instances, yet have very old alive instances in its queue. The same is true for the replacement criteria options. If you choose **DDS\_FULLY\_PROCESSED\_INSTANCE\_REMOVAL** (for example), *Connex* will not look for empty instances first and then fully processed instances; the LRU instance that is considered fully-processed will be replaced.

If no replaceable instance exists after the instance replacement kinds above have been applied, the sample for the new instance will be considered lost with the reason **LOST\_BY\_INSTANCES\_LIMIT** in the [40.7.7 SAMPLE\\_LOST Status on page 636](#); the instance will not be inserted into the *DataReader* queue.

## 48.2.4 Example

The **max\_samples\_per\_remote\_writer** value affects sharing and starvation. **max\_samples\_per\_remote\_writer** can be set to less than the **RESOURCE\_LIMITS** QosPolicy's **max\_samples** to prevent a single *DataWriter* from starving others. This control is especially important for *Topics* that have their [47.17 OWNERSHIP QosPolicy on page 833](#) set to **SHARED**.

In the case of **EXCLUSIVE** ownership, a lower-strength remote *DataWriter* can "starve" a higher-strength remote *DataWriter* by making use of more of the *DataReader*'s resources, an undesirable condition. In the case of **SHARED** ownership, a remote *DataWriter* may starve another remote *DataWriter*, making the sharing not really equal.

## 48.2.5 Properties

This QoS Policy cannot be modified after the *DataReader* is created.

It only applies to *DataReaders*, so there are no restrictions for setting it compatibly on the *DataWriter*.

## 48.2.6 Related QoS Policies

- [47.22 RESOURCE\\_LIMITS QoS Policy on page 850](#)
- [47.17 OWNERSHIP QoS Policy on page 833](#)

## 48.2.7 Applicable DDS Entities

- [Chapter 40 DataReaders on page 615](#)

## 48.2.8 System Resource Considerations

Increasing any of the “initial” values in this policy will increase the amount of memory allocated by *Connex* when a new *DataReader* is created. Increasing any of the “max” values will not affect the initial memory allocated for a new *DataReader*, but will affect how much additional memory may be allocated as needed over the *DataReader*'s lifetime.

Setting a max value greater than an initial value thus allows your application to use memory more dynamically and efficiently in the event that the size of the application is not well-known ahead of time. However, *Connex* may dynamically allocate memory in response to network communications.

## 48.3 READER\_DATA\_LIFECYCLE QoS Policy

This policy controls the behavior of the *DataReader* with regards to the lifecycle of the data instances it manages, that is, the data instances that have been received and for which the *DataReader* maintains some internal resources.

When a *DataReader* receives data, it is stored in a receive queue for the *DataReader*. The user application may either take the data from the queue or leave it there. This QoS controls whether or not *Connex* will automatically remove data from the receive queue (so that user applications cannot access it afterward) when *Connex* detects that there are no more *DataWriters* alive for that data.

*DataWriters* may also call **dispose()** on its data, informing *DataReaders* that the data no longer exists. This QoS Policy also controls whether or not *Connex* automatically removes disposed data from the receive queue.

For keyed Topics, the consideration of removing DDS data samples from the receive queue is done on a per instance (key) basis. Thus when *Connex* detects that there are no longer *DataWriters* alive for a certain key value for a *Topic* (an instance of the *Topic*), it can be configured to remove all DDS data samples for a certain instance (key). *DataWriters* also can dispose its data on a per instance basis. Only the DDS data samples of disposed instances would be removed by *Connex* if so configured.

This policy helps purge untaken DDS samples from not-alive-instances and thus may prevent a *DataReader* from reclaiming resources. With this policy, the untaken DDS samples from not-alive-instances are purged and treated as if the DDS samples were taken after the specified amount of time.

The *DataReader* internally maintains the DDS samples that have not been taken by the application, subject to the constraints imposed by other QoS policies such as [47.12 HISTORY QoS Policy on page 818](#) and [47.22 RESOURCE\\_LIMITS QoS Policy on page 850](#).

The *DataReader* also maintains information regarding the identity, view-state, and instance-state of data instances, even after all DDS samples have been ‘taken’ (see [41.3 Accessing DDS Data Samples with Read or Take on page 665](#)). This is needed to properly compute the states when future DDS samples arrive.

Under normal circumstances, a *DataReader* can only reclaim all resources for instances for which there are no *DataWriters* and for which all DDS samples have been ‘taken.’ The last DDS sample taken by the *DataReader* for that instance will have an instance state of `NOT_ALIVE_NO_WRITERS` or `NOT_ALIVE_DISPOSED_INSTANCE` (depending on whether or not the instance was disposed by the last *DataWriter* that owned it.) If you are using the default (infinite) values for this QoS Policy, this behavior can cause problems if the application does not ‘take’ those DDS samples for some reason. The ‘untaken’ DDS samples will prevent the *DataReader* from reclaiming the resources and they would remain in the *DataReader* indefinitely.

A *DataReader* can also reclaim all resources for instances that have an instance state of `NOT_ALIVE_DISPOSED` and for which all DDS samples have been ‘taken’. *DataReaders* will only reclaim resources in this situation when `autopurge_disposed_instances_delay` has been set to zero.

It includes the members in [Table 48.4 DDS\\_ReaderDataLifecycleQoS Policy](#).

**Table 48.4 DDS\_ReaderDataLifecycleQoS Policy**

Type	Field Name	Description
DDS_Duration_t	autopurge_nowriter_samples_delay	<p>Minimum duration for which the <i>DataReader</i> will maintain samples regarding an instance once its <b>instance_state</b> becomes <b>NOT_ALIVE_NO_WRITERS</b>. An instance will transition to <b>NOT_ALIVE_NO_WRITERS</b> when all known writers for the instance have lost liveliness, been deleted, or unregistered from the instance.</p> <p>After this time elapses, the <i>DataReader</i> will purge all samples for the instance even if they have not been read by the application. These samples will be dropped. (See <a href="#">expired_dropped_sample_count</a> in <a href="#">40.7.2 DATA_READER_CACHE_STATUS on page 627</a>.) This purge is done lazily when space is needed for other samples or instances (for example, when a resource limit such as <a href="#">max_samples on page 850</a> is hit).</p> <p>Default: INFINITE</p>
DDS_Duration_t	autopurge_disposed_samples_delay	<p>Minimum duration for which the <i>DataReader</i> will maintain samples for an instance once its <b>instance_state</b> becomes <b>NOT_ALIVE_DISPOSED</b>.</p> <p>After this time elapses, the <i>DataReader</i> will purge all samples for the instance even if they have not been read by the application. These samples will be dropped. (See <a href="#">expired_dropped_sample_count</a> in <a href="#">40.7.2 DATA_READER_CACHE_STATUS on page 627</a>.) This purge is done lazily when space is needed for other samples or instances (for example, when a resource limit such as <a href="#">max_samples on page 850</a> is hit).</p> <p>Default: INFINITE</p>

Table 48.4 DDS\_ReaderDataLifecycleQoSPolicy

Type	Field Name	Description
DDS_Duration_t	autopurge_disposed_instances_delay	<p>Minimum duration for which the <i>DataReader</i> will maintain "active state" information about a received instance once its <b>instance_state</b> becomes <b>NOT_ALIVE_DISPOSED</b>, and there are no samples for the instance in the <i>DataReader</i> queue. (See <a href="#">40.8.7 Active State and Minimum State on page 649</a>.) Note: only values of 0 or INFINITE are currently supported. A value of 0 will purge an instance's state immediately after the instance state transitions to <b>NOT_ALIVE_DISPOSED</b>, as long as all samples, including the dispose sample, associated with that instance have been 'taken.'</p> <p>After this time elapses, when the last sample for the disposed instance is taken, the <i>DataReader</i> will keep only a minimum amount of state about the instance. To disable retention of even this minimum state after the delay period, also set <b>keep_minimum_state_for_instances</b> to FALSE in the <a href="#">48.2 DATA_READER_RESOURCE_LIMITS QoSPolicy (DDS Extension) on page 876</a>. See <a href="#">48.2.2 keep_minimum_state_for_instances on page 882</a>.</p> <p>Default: INFINITE</p>
DDS_Duration_t	autopurge_nowriter_instances_delay	<p>Minimum duration for which the <i>DataReader</i> will maintain "active state" information about a received instance once its <b>instance_state</b> becomes <b>NOT_ALIVE_NO_WRITERS</b> and there are no samples for the instance in the <i>DataReader</i> queue. (See <a href="#">40.8.7 Active State and Minimum State on page 649</a>.)</p> <p>An instance will transition to <b>NOT_ALIVE_NO_WRITERS</b> when all known writers for the instance have lost liveliness, been deleted, or unregistered from the instance. After this time elapses, when the last sample for the instance without writers is taken, the <i>DataReader</i> will keep only the minimum state about the instance.</p> <p>To disable retention of even this minimum state after the delay period, also set <b>keep_minimum_state_for_instances</b> to FALSE in the <a href="#">48.2 DATA_READER_RESOURCE_LIMITS QoSPolicy (DDS Extension) on page 876</a>. See <a href="#">48.2.2 keep_minimum_state_for_instances on page 882</a>.</p> <p>(Note: only values of 0 or INFINITE are currently supported. A value of 0 will purge an instance's state immediately after the instance state transitions to <b>NOT_ALIVE_NO_WRITERS</b>, as long as all samples, including the no_writers sample, associated with that instance have been 'taken.')</p> <p>Default: 0</p>

### 48.3.1 Properties

This QoS policy *can* be modified after the *DataReader* is enabled.

It only applies to *DataReaders*, so there are no RxO restrictions for setting it compatibly on the *DataWriter*.

### 48.3.3 Applicable DDS Entities

- [Chapter 40 DataReaders on page 615](#)

## 48.3.4 System Resource Considerations

None.

### 48.4 TIME\_BASED\_FILTER QoSPolicy

The `TIME_BASED_FILTER` QoSPolicy allows you to specify that data should not be delivered more than once per specified period for data-instances of a *DataReader*—regardless of how fast *DataWriters* are publishing new DDS samples of the data-instance.

This QoS policy allows you to optimize resource usage (CPU and possibly network bandwidth) by only delivering the required amount of data to different *DataReaders*.

*DataWriters* may send data faster than needed by a *DataReader*. For example, a *DataReader* of sensor data that is displayed to a human operator in a GUI application does not need to receive data updates faster than a user can reasonably perceive changes in data values. This is often measure in tenths (0.1) of a second up to several seconds. However, a *DataWriter* of sensor information may have *DataReaders* that are processing the sensor information to control parts of the system and thus need new data updates in measures of hundredths (0.01) or thousandths (0.001) of a second.

With this QoS policy, different *DataReaders* can set their own time-based filters, so that data published faster than the period set by a *DataReader* will be dropped by the middleware and not delivered to the *DataReader*. Note that all filtering takes place on the reader side.

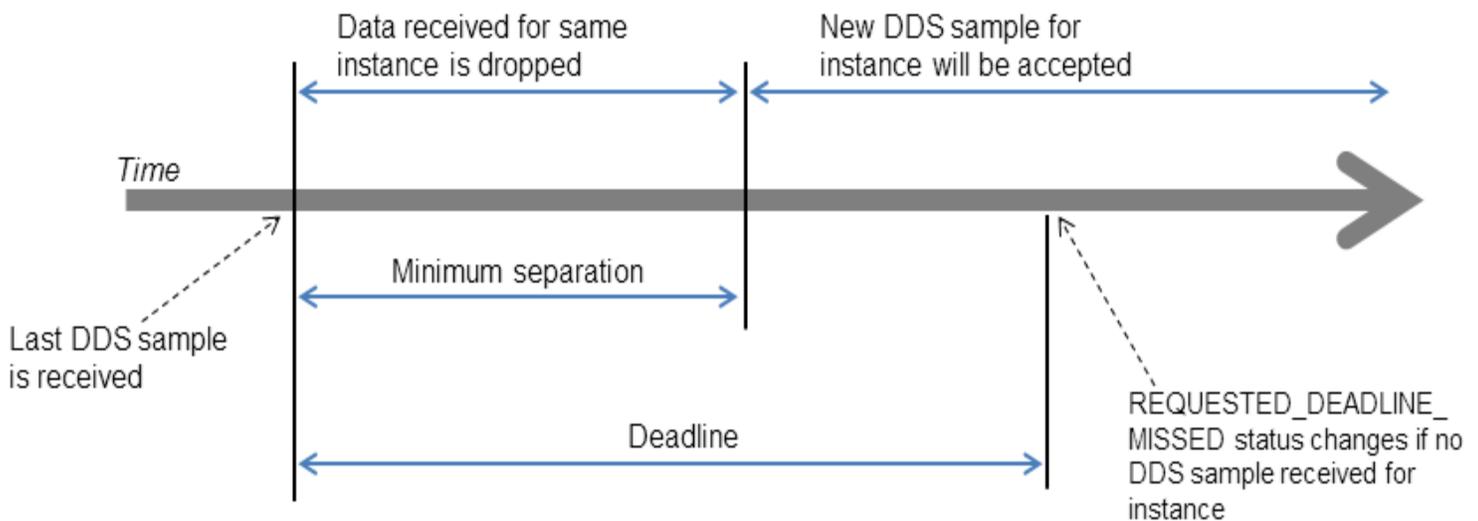

It includes the member in [Table 48.5 DDS\\_TimeBasedFilterQoSPolicy](#). For the default and valid range, please refer to the API Reference HTML documentation.

**Table 48.5 DDS\_TimeBasedFilterQoSPolicy**

Type	Field Name	Description
DDS_Duration_t	minimum_separation	Minimum separation time between DDS samples of the same instance. Must be <= <b>DEADLINE::period</b>

As seen in [Figure 48.1: Accepting Data for DataReaders on the next page](#), it is inconsistent to set a *DataReader*'s **minimum\_separation** longer than its [47.7 DEADLINE QoSPolicy on page 804 period](#).

Figure 48.1: Accepting Data for DataReaders

DDS data samples for a *DataReader* can be filtered out using the `TIME_BASED_FILTER` QoS (`minimum_separation`). Once a DDS sample for an instance has been received, *Connex* will accept but drop any new data samples for the same instance that arrives within the time specified by `minimum_separation`. After the `minimum_separation`, a new DDS sample that arrives is accepted and stored in the receive queue, and the timer starts again. If no DDS samples arrive by the `DEADLINE`, the `REQUESTED_DEADLINE_MISSED` status will be changed and Listeners called back if installed.

This QoS Policy allows a *DataReader* to subsample the data being published for a data instance by *DataWriters*. If a user application only needs new DDS samples for a data instance to be received at a specified period, then there is no need for *Connex* to deliver data faster than that period. However, whether or not data being published by a *DataWriter* at a faster rate than set by the `TIME_BASED_FILTER` QoS is sent on the wire depends on several factors, including whether the *DataReader* is receiving the data reliably and if the data is being sent via multicast for multiple *DataReaders*.

For best effort data delivery, if the data type is unkeyed and the *DataWriter* has an infinite liveliness `lease_duration` (47.15 `LIVELINESS` QoS Policy on page 825), *Connex* will only send as many packets to a *DataReader* as required by the `TIME_BASED_FILTER`, no matter how fast the *DataWriter*'s `write()` function is called.

For multicast data delivery to multiple *DataReaders*, the *DataReader* with the lowest `TIME_BASED_FILTER` `minimum_separation` determines the *DataWriter*'s send rate. For example, if a *DataWriter* sends multicast to two *DataReaders*, one with `minimum_separation` of 2 seconds and one with `minimum_separation` of 1 second, the *DataWriter* will send every 1 second.

Other configurations (for example, when the *DataWriter* is reliable, or the data type is keyed, or the *DataWriter* has a finite liveliness `lease_duration`) must send all data published by the *DataWriter*. On reception, only the data that passes the `TIME_BASED_FILTER` will be stored in the *DataReader*'s

receive queue. Extra data will be accepted but dropped. Note that filtering is only applied on ‘alive’ DDS samples (that is, DDS samples that have *not* been disposed/unregistered).

## 48.4.1 Example

The purpose of this QosPolicy is to prevent fast *DataWriters* from overwhelming a *DataReader* that cannot process the data at the rate the data is being published. In certain configurations, the number of packets sent by *Connex*t can also be reduced thus minimizing the consumption of network bandwidth.

You may want to change the **minimum\_separation** between DDS data samples for one or more of the following reasons:

- The *DataReader* is connected to the network via a low-bandwidth connection that is unable to sustain the amount of traffic generated by the matched *DataWriter(s)*.
- The rate at which the matched *DataWriter(s)* can generate DDS samples is faster than the rate at which the *DataReader* can process them. Or faster than needed by the *DataReader*. For example, a graphical user interface seldom needs to be updated faster than 30 times a second, even if new data values are available much faster.
- The resource limits of the *DataReader* are constrained relative to the number of DDS samples that could be generated by the matched *DataWriter(s)*. Too many packets coming at once will cause them to be exhausted before the *DataReader* has time to process them.

## 48.4.2 Properties

This QosPolicy can be modified at any time.

It only applies to *DataReaders*, so there are no restrictions for setting it compatibly on the *DataWriter*.

## 48.4.3 Related QosPolicies

- [47.21 RELIABILITY QosPolicy on page 845](#)
- [47.7 DEADLINE QosPolicy on page 804](#)
- [48.5 TRANSPORT\\_MULTICAST QosPolicy \(DDS Extension\) on the next page](#)

## 48.4.4 Applicable DDS Entities

- [Chapter 40 DataReaders on page 615](#)

## 48.4.5 System Resource Considerations

Depending on the values of other QosPolicies such as RELIABILITY and TRANSPORT\_MULTICAST, this policy may be able to decrease the usage of network bandwidth and CPU by preventing unneeded packets from being sent and processed.

## 48.5 TRANSPORT\_MULTICAST QosPolicy (DDS Extension)

This QosPolicy specifies the multicast address on which a *DataReader* wants to receive its data. It can also specify a port number as well as a subset of the available transports with which to receive the multicast data.

By default, *DataWriters* will send individually addressed packets for each *DataReader* that subscribes to the topic of the *DataWriter*—this is known as unicast delivery. Thus, as many copies of the data will be sent over the network as there are *DataReaders* for the data. The network bandwidth used by a *DataWriter* will thus increase linearly with the number of *DataReaders*.

Multicast is a concept supported by some transports, most notably UDP/IP, so that a *single* packet on the network can be addressed such that it is received by multiple nodes. This is more efficient when the same data needs to be sent to multiple nodes. By using multicast, the network bandwidth usage will be constant, independent of the number of *DataReaders*.

Coordinating the multicast address specified by *DataReaders* can help optimize network bandwidth usage in systems where there are multiple *DataReaders* for the same *Topic*.

The QosPolicy structure includes the members in [Table 48.6 DDS\\_TransportMulticastQosPolicy](#).

**Table 48.6 DDS\_TransportMulticastQosPolicy**

Type	Field Name	Description
DDS_TransportMulticastSettingSeq (A sequence of the type shown in <a href="#">Table 48.7 DDS_TransportMulticastSetting_t</a> )	value	A sequence of up to 16 multicast locators. This is a hard limit that cannot be increased. However, this limit can be <i>decreased</i> by configuring the <i>DomainParticipant</i> property <code>dds.domain_participant.max_announced_locator_list_size</code> . For more information on the locator format, see <a href="#">24.1.1 Locator Format on page 327</a> .
DDS_TransportMulticastKind	kind	<p>This field can be set to one of the following two values: DDS_AUTOMATIC_TRANSPORT_MULTICAST_QOS or DDS_UNICAST_ONLY_TRANSPORT_MULTICAST_QOS.</p> <p>If it is set to DDS_AUTOMATIC_TRANSPORT_MULTICAST_QOS, the behavior depends on the content of DDS_TransportMulticastQosPolicy::value:</p> <p>If DDS_TransportMulticastQosPolicy::value does not have any elements, multicast will not be used.</p> <p>If DDS_TransportMulticastQosPolicy::value first element has an empty address, the address will be obtained from DDS_TransportMulticastMappingQosPolicy.</p> <p>If none of the elements in DDS_TransportMulticastQosPolicy::value are empty, and at least one element has a valid address, then that address will be used.</p> <p>If it is set to DDS_UNICAST_ONLY_TRANSPORT_MULTICAST_QOS, then multicast will not be used.</p>

Table 48.7 DDS\_TransportMulticastSetting\_t

Type	Field Name	Description
DDS_StringSeq	transports	A sequence of transport aliases that specifies which transports should be used to receive multicast messages for this <i>DataReader</i> .
char *	receive_address	A multicast group address to which the <i>DataWriter</i> should send data for this <i>DataReader</i> .
DDS_Long	receive_port	The port that should be used in the addressing of multicast messages destined for this <i>DataReader</i> . A value of 0 will cause <i>Connex</i> t to use a default port number based on domain ID. See <a href="#">Chapter 23 Ports Used for Discovery on page 319</a> .

To take advantage of multicast, the value of this QoSPolicy must be coordinated among all of the applications on a network for *DataReaders* of the same *Topic*. For a *DataWriter* to send a single packet that will be received by all *DataReaders* simultaneously, the same multicast address must be used.

To use this QoSPolicy, you will also need to specify a port number. A port number of 0 will cause *Connex*t to automatically use a default value. As explained in [Chapter 23 Ports Used for Discovery on page 319](#), the default port number for multicast addresses is based on the domain ID. Should you choose to use a different port number, then for every unique port number used by Entities in your application, depending on the transport, *Connex*t may create a thread to process messages received for that port on that transport. See [Part 11: Connex](#)t Threading Model (on page 1180) for more about threads.

Threads are created on a per-transport basis, so if this QoSPolicy specifies multiple **transports** for a **receive\_port**, then a thread may be created for each transport for that unique port. Some transports may be able to share a single thread for different ports, others can not. Note that different Entities can share the same port number, and thus, the same thread will process all of the data for all of the Entities sharing the same port number for a transport.

Also note that if the port number specified by this QoS is the same as a port number specified by a TRANSPORT\_UNICAST QoS, then the transport may choose to process data received both via multicast and unicast with a single thread. Whether or not a transport must use different threads to process data received via multicast or unicast for the same port number depends on the implementation of the transport.

#### Notes:

- The same multicast address can be used by *DataReaders* of different *Topics*.
- Even though the TRANSPORT\_MULTICAST QoS allows you to specify multiple multicast addresses for a *DataReader*, *Connex*t currently only uses one multicast address (the first in the sequence) per *DataReader*.

- If a *DataWriter* is using the [47.16 MULTI\\_CHANNEL QoS Policy \(DDS Extension\)](#) on [page 830](#), the multicast addresses specified in the `TRANSPORT_MULTICAST` QoS Policy are ignored by that *DataWriter*. The *DataWriter* will not publish DDS samples on those locators.

## 48.5.1 Example

In an airport, there may be many different monitors that display current flight information. Assuming each monitor is controlled by a networked application, network bandwidth would be greatly reduced if flight information was published using multicast.

[Figure 48.2: Setting Up a Multicast DataReader below](#) shows an example of how to set this QoS Policy.

### Figure 48.2: Setting Up a Multicast DataReader

```
...
DDS_DataReaderQos  reader_qos;
reader_listener = new HelloWorldListener();
if (reader_listener == NULL) {
    // handle error
}
// Get default data reader QoS to customize
retcode = subscriber->get_default_datareader_qos(reader_qos);
if (retcode != DDS_RETCODE_OK) {
    // handle error
}
// Set up multicast reader
reader_qos.multicast.value.ensure_length(1,1);
reader_qos.multicast.value[0].receive_address =
    DDS_String_dup("239.192.0.1");
reader = subscriber->create_datareader(
    topic, reader_qos,
    reader_listener, DDS_STATUS_MASK_ALL);
```

## 48.5.2 Properties

This QoS Policy cannot be modified after the *Entity* is created.

For compatibility between *DataWriters* and *DataReaders*, the *DataWriter* must be able to send to the multicast address that the *DataReader* has specified.

## 48.5.3 Related QoS Policies

## 48.5.4 Applicable DDS Entities

- [16.3 DomainParticipants on page 81](#)
- [Chapter 40 DataReaders on page 615](#)

## 48.5.5 System Resource Considerations

On Ethernet-based systems, the number of multicast addresses that can be “listened” to by the network interface card is usually limited. The exact number of multicast addresses that can be monitored simultaneously by a NIC depends on its manufacturer. Setting a multicast address for a *DataReader* will use up one of the multicast-address slots of the NIC.

What happens if the number of different multicast addresses used by different *DataReaders* across different applications on the same node exceeds the total number supported by a NIC depends on the specific operating system. Some will prevent you from configuring too many multicast addresses to be monitored.

Many operating systems will accommodate the extra multicast addresses by putting the NIC in promiscuous mode. This means that the NIC will pass every Ethernet packet to the operating system, and the operating system will pass the packets with the specified multicast addresses to the application(s). This results in extra CPU usage. We recommend that your applications do not use more multicast addresses on a single node than the NICs on that node can listen to simultaneously in hardware.

Depending on the implementation of a transport, *Connex*t may need to create threads to receive and process data on a unique-port-number basis. Some transports can share the same thread to process data received for different ports; others like UDPv4 must have different threads for different ports. In addition, if the same port is used for both unicast and multicast, the transport implementation will determine whether or not the same thread can be used to process both unicast and multicast data. For UDPv4, only one thread is needed per port— independent of whether the data was received via unicast or multicast data. See [Chapter 66 Receive Threads on page 1187](#) for more information.

## 48.6 TYPE\_CONSISTENCY\_ENFORCEMENT QoSPolicy

The `TypeConsistencyEnforcementQoSPolicy` defines the rules that determine whether the type used to publish a given topic is consistent with the type used to subscribe to it.

**Note:** If the type information is not available for a topic (and `force_type_validation` is false), these rules do not apply.

The `QoSPolicy` structure includes the members in the following table.

Table 48.8 DDS\_TypeConsistencyEnforcementQosPolicy

Type	Field Name	Description
DDS_TypeConsistencyKind	kind	<p>Can be any of the following values:</p> <ul style="list-style-type: none"> <li>AUTO_TYPE_COERCION (default)</li> <li>ALLOW_TYPE_COERCION</li> <li>DISALLOW_TYPE_COERCION</li> </ul> <p>See below for details.</p>
DDS_Boolean	ignore_sequence_bounds	<p>Controls whether sequence bounds are taken into consideration for type assignability.</p> <p>If false, a <i>DataWriter</i>'s type containing a sequence with a larger maximum length will not be assigned to a <i>DataReader</i>'s type containing a sequence with a smaller maximum length. Since the types are not assignable, the <i>DataReader</i> will not match when type information is available.</p> <p>If true, a sequence in a <i>DataReader</i>'s type can have a maximum length smaller than that of a sequence in a <i>DataWriter</i>'s type. The types will be assignable, and the <i>DataReader</i> will match; however, when the length of the sequence in a particular <i>DataWriter</i>'s sample is larger than the <i>DataReader</i>'s maximum length, that sample is discarded. See "Verifying Sample Consistency: Sample Assignability" in the <i>Core Libraries Extensible Types Guide</i>.</p> <p>Default: true</p>
DDS_Boolean	ignore_string_bounds	<p>Controls whether string bounds are taken into consideration for type assignability.</p> <p>If false, then a <i>DataWriter</i>'s type containing a string with a larger maximum length will not be assigned to a <i>DataReader</i>'s type containing a string with a smaller maximum length. Since the types are not assignable, the <i>DataReader</i> will not match when type information is available.</p> <p>If true, then a string in a <i>DataReader</i>'s type can have a maximum length smaller than that of a string in a <i>DataWriter</i>'s type. They are assignable, and the <i>DataReader</i> will match; however, when the length of the string in a particular <i>DataWriter</i>'s sample is larger than the <i>DataReader</i>'s maximum length, that sample is discarded. See "Verifying Sample Consistency: Sample Assignability" in the <i>Core Libraries Extensible Types Guide</i>.</p> <p>Default: true</p>
DDS_Boolean	ignore_member_names	<p>Controls whether member names are taken into consideration for type assignability.</p> <p>If false, types containing members with the same ID and different names are not assignable to each other. Since the types are not assignable, the <i>DataReader</i> will not match when type information is available.</p> <p>If true, members of a type can change their name while keeping their member ID. For example, MyType and MyTypeSpanish are only assignable if <b>ignore_member_names</b> is true:</p> <pre> struct MyType {     @id(10) int32 x;     @id(20) int32 angle; }; struct MyTypeSpanish {     @id(10) int32 x;     @id(20) int32 angulo; };                     </pre> <p>Since the types are assignable, the <i>DataReader</i> will match.</p> <p>Default: false</p>
DDS_Boolean	prevent_type_widening	<p>Controls whether type widening is allowed. A type T2 widens a type T1 when T2 contains required members that are not present in T1.</p> <p>If a <i>DataReader</i> of T2 sets <b>prevent_type_widening</b> to true, then the <i>DataReader</i> will not be matched with a <i>DataWriter</i> of T1 with fewer members because T1 is not assignable to T2.</p> <p>If a <i>DataReader</i> of T2 sets <b>prevent_type_widening</b> to false, then the <i>DataReader</i> will match with the <i>DataWriter</i> of T1. The <i>DataReader</i> will assume a value for members in T2 that are not in T1. See "Prevent Type Widening" below.</p> <p>Default: false</p>

Table 48.8 DDS\_TypeConsistencyEnforcementQosPolicy

Type	Field Name	Description
DDS_Boolean	force_type_validation	Controls whether type information must be available in order to complete matching between a <i>DataWriter</i> and this <i>DataReader</i> . If false, matching may occur as long as the type names match. Note that if the types have the same name, but the types are not assignable, <i>DataReaders</i> may fail to deserialize incoming data samples. If <b>force_type_validation</b> is true and no type information is available, then the <i>DataReader</i> will not match. Default: false
DDS_Boolean	ignore_enum_literal_names	Controls whether enumeration constant names are taken into consideration for type assignability. If the option is set to true, then enumeration constants may change their names, but not their values, and still maintain type assignability. If the option is set to false, then in order for enumerations to be assignable, any constant that has the same value in both enumerations must also have the same name. For example, enum Color {RED = 0} and enum Color {ROJO = 0} are assignable if and only if ignore_enum_literal_names is true. Default: false

The type-consistency enforcement rules consist of two steps:

1. If both the *DataWriter* and *DataReader* specify a *TypeObject*, it is considered first. If the *DataReader* allows type coercion, then its type must be assignable from the *DataWriter*'s type, taking into account the values of **prevent\_type\_widening**, **ignore\_sequence\_bounds**, **ignore\_string\_bounds**, **ignore\_member\_names**, and **ignore\_enum\_literal\_names**. If the *DataReader* does not allow type coercion, then its type must be equivalent to the type of the *DataWriter*.
2. If either the *DataWriter* or the *DataReader* does not provide a *TypeObject* definition, then the registered type names are examined. The *DataReader*'s and *DataWriter*'s registered type names must match exactly, as was true in *Connex* releases prior to 5.0. This step will fail if **force\_type\_validation** is true, regardless of the type names.

If either Step 1 or Step 2 fails, the *Topics* associated with the *DataReader* and *DataWriter* are considered to be inconsistent and the [18.2.1 INCONSISTENT\\_TOPIC Status on page 256](#) is updated.

The default enforcement kind is **DDS\_AUTO\_TYPE\_COERCION**. This default kind translates to **DDS\_ALLOW\_TYPE\_COERCION**, except in the following cases:

- When a Zero Copy *DataReader* is used, the kind is translated to **DDS\_DISALLOW\_TYPE\_COERCION**.
- When the middleware is introspecting the built-in topic data declaration of a remote *DataReader* in order to determine whether it can match with a local *DataWriter*, if it observes that no *TypeConsistencyEnforcementQosPolicy* value is provided (as would be the case when communicating with a Service implementation not in conformance with this specification), it assumes a kind of **DDS\_DISALLOW\_TYPE\_COERCION**.

## 48.6.1 Values for TypeConsistencyKind

- AUTO\_TYPE\_COERCION (default)

For a regular *DataReader*, this default value is translated to ALLOW\_TYPE\_COERCION. For a Zero Copy *DataReader*, this default value is translated to DISALLOW\_TYPE\_COERCION. (See [34.1.5 Zero Copy Transfer Over Shared Memory on page 516](#) for information on why a Zero Copy *DataReader* requires the DISALLOW\_TYPE\_COERCION option.)

- DISALLOW\_TYPE\_COERCION

With this setting, the *DataWriter* and *DataReader* must support the same data type in order for them to communicate. (This is the degree of enforcement required by the OMG DDS Specification prior to the [OMG ‘Extensible and Dynamic Topic Types for DDS’ specification](#).)

When *Connex* is introspecting the built-in topic data declaration of a remote *DataWriter* or *DataReader*, if no TypeConsistencyEnforcementQosPolicy value is provided (as would be the case when communicating with an implementation not in conformance with the Extensible and Dynamic Topic Types for DDS" (DDS-XTypes) specification), *Connex* shall assume a **kind** of DISALLOW\_TYPE\_COERCION.

- ALLOW\_TYPE\_COERCION

With this setting, the *DataWriter* and the *DataReader* need not support the same data type in order for them to communicate, as long as the *DataReader*'s type is assignable from the *DataWriter*'s type.

For example, the following two extensible types will be assignable to each other since *MyDerivedType* contains all the members of *MyBaseType* (**member\_1**) plus an additional element (**member\_2**).

```
struct MyBaseType {
    int32 member_1;
};
struct MyDerivedType: MyBaseType {
    int32 member_2;
};
```

Even if *MyDerivedType* was not explicitly inherited from *MyBaseType*, the types would still be assignable. For example:

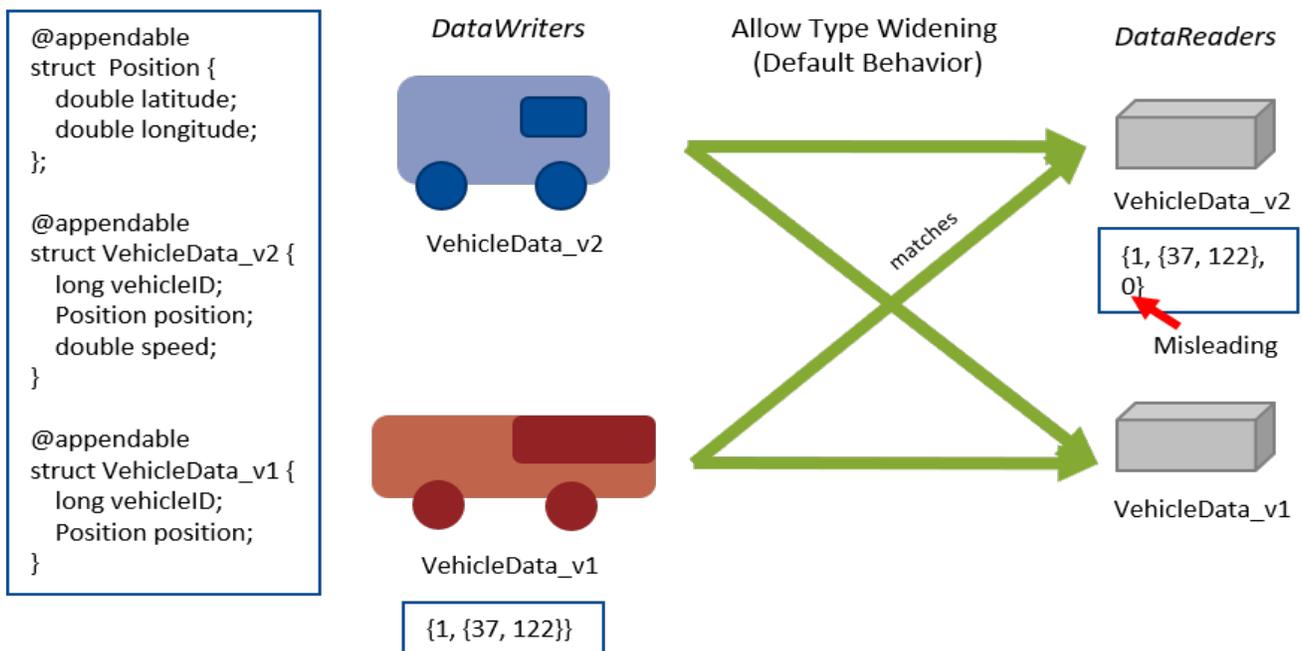

```
struct MyBaseType {
    int32 member_1;
};
struct MyDerivedType {
    int32 member_1;
    int32 member_2;
};
```

For more information, see the [RTI Connex Core Libraries Extensible Types Guide](#) and the [OMG 'Extensible and Dynamic Topic Types for DDS' Specification](#).

## 48.6.2 Prevent Type Widening

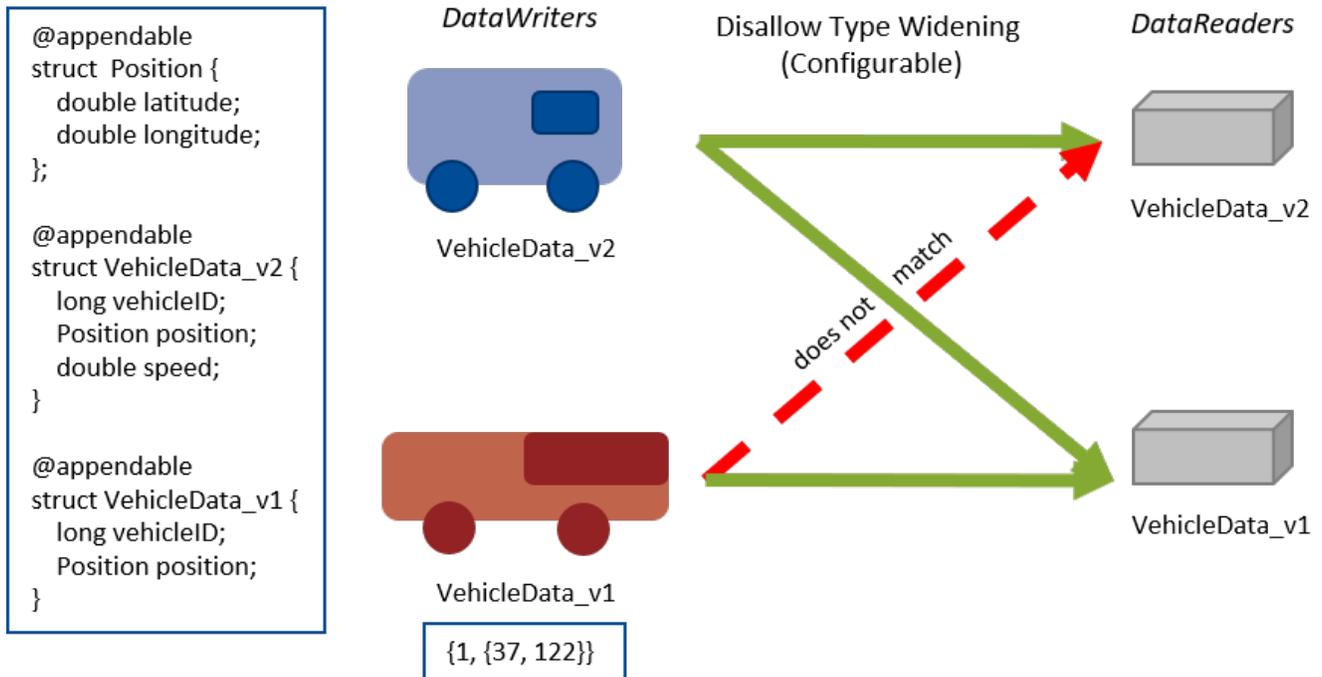

The `prevent_type_widening` field determines whether type widening is allowed. In [Figure 48.3: prevent\\_type\\_widening = false below](#), `VehicleData_v2` has three members and `VehicleData_v1` two members. With type widening allowed, the narrower car (`VehicleData_v1`, with two members) can write to the wider car (`VehicleData_v2`), but notice that the `DataReader` assumes a value that might be misleading (in this case, a default speed of zero).

Figure 48.3: `prevent_type_widening = false`

If widening is not allowed ([Figure 48.4: prevent\\_type\\_widening = true on the next page](#)), `VehicleData_v1` and `VehicleData_v2` do not communicate with each other.

Figure 48.4: prevent\_type\_widening = true

### 48.6.3 Properties

This QoS Policy cannot be modified after the *DataReader* is enabled.

It only applies to *DataReaders*, so there is no requirement that the publishing and subscribing sides use compatible values.

### 48.6.4 Related QoS Policies

- None.

### 48.6.5 Applicable Entities

- [Chapter 40 DataReaders on page 615](#)

### 48.6.6 System Resource Considerations

- None.

# Chapter 49 Configuring Qos Programmatically

Each type of *Entity* has an associated set of QoS Policies (see [Chapter 42 All QoS Policies on page 683](#)). QoS Policies allow you to configure and set properties for the Entity.

While most QoS Policies are defined by the DDS specification, some are offered by *Connex* as extensions to control parameters specific to the implementation.

There are two ways to specify a QoS policy:

- Programmatically, as described in this section.
- QoS Policies can also be configured from XML resources (files, strings)—with this approach, you can change the QoS without recompiling the application. The QoS settings are automatically loaded by the *DomainParticipantFactory* when the first *DomainParticipant* is created. See [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

The `get_qos()` operation retrieves the current values for the set of QoS Policies defined for the *Entity*.

QoS Policies can be set programmatically when an Entity is created, or modified with the Entity's `set_qos()` operation.

The `set_qos()` operation sets the QoS Policies of the entity. Note: not all QoS Policy changes will take effect instantaneously; there may be a delay since some QoS Policies set for one entity, for example, a *DataReader*, may actually affect the operation of a matched entity in another application, for example, a *DataWriter*.

The `get_qos()` and `set_qos()` operations are passed QoS structures that are specific to each derived entity class, since the set of QoS Policies that effect each class of *Entities* is different.

The `equals()` operation compares two Entity's QoS structures for equality. It takes two parameters for the two *Entities*' QoS structures to be compared, then returns TRUE if they are equal (all values are the same) or FALSE if they are not equal.

Each QoSPolicy has default values (listed in the API Reference HTML documentation). If you want to use custom values, there are three ways to change QoSPolicy settings:

- Before Entity creation (if custom values should be used for multiple *Entities*). See [49.1 Changing the QoS Defaults Used to Create DDS Entities: `set\_default\*\_qos\(\)`](#) below.
- During Entity creation (if custom values are only needed for a particular Entity). See [49.2 Setting QoS During Entity Creation on the next page](#).
- After Entity creation (if the values initially specified for a particular Entity are no longer appropriate). See [49.3 Changing the QoS for an Existing Entity on page 903](#).

Regardless of when or how you make QoS changes, there are some rules to follow:

- Some QoS Policies interact with each other and thus must be set in a consistent manner. For instance, the maximum value of the HISTORY QoS Policy's *depth* parameter is limited by values set in the RESOURCE\_LIMITS QoS Policy. If the values within a QoS Policy structure are inconsistent, then `set_qos()` will return the error INCONSISTENT\_POLICY, and the operation will have no effect.
- Some policies can only be set when the *Entity* is created, or before the *Entity* is enabled. Others can be changed at any time. In general, all standard DDS QoS Policies can be changed before the *Entity* is enabled. A subset can be changed after the *Entity* is enabled. *Connex*-specific QoS Policies either cannot be changed after creation or can be changed at any time. The changeability of each QoS Policy is documented in the API Reference HTML documentation as well as in [Table 42.1 QoS Policies](#). If you attempt to change a policy after it cannot be changed, `set_qos()` will fail with a return IMMUTABLE\_POLICY.

## 49.1 Changing the QoS Defaults Used to Create DDS Entities: `set_default*_qos()`

Each parent factory has a set of default QoS settings that are used when the child entity is created. The *DomainParticipantFactory* has default QoS values for creating *DomainParticipants*. A *DomainParticipant* has a set of default QoS for each type of entity that can be created from the *DomainParticipant* (*Topic*, *Publisher*, *Subscriber*, *DataWriter*, and *DataReader*). Likewise, a *Publisher* has a set of default QoS values used when creating *DataWriters*, and a *Subscriber* has a set of default QoS values used when creating *DataReaders*.

An entity's QoS are set when it is created. Once an entity is created, all of its QoS—for itself and its child *Entities*—are fixed unless you call `set_qos()` or `set_qos_with_profile()` on that entity. Calling

`set_default_<entity>_qos()` on a parent entity will have no effect on child *Entities* that have already been created.

You can change these default values so that they are automatically applied when new child *Entities* are created. For example, suppose you want all *DataWriters* for a particular *Publisher* to have their RELIABILITY QoSPolicy set to RELIABLE. Instead of making this change for each *DataWriter* when it is created, you can change the default used when any *DataWriter* is created from the *Publisher* by using the *Publisher*'s `set_default_datawriter_qos()` operation.

```
DDS_DataWriterQos default_datawriter_qos;
// get the current default values
publisher->get_default_datawriter_qos(default_datawriter_qos);
// change to desired default values
default_datawriter_qos.reliability.kind =
    DDS_RELIABLE_RELIABILITY_QOS;
// set the new default values
publisher->set_default_datawriter_qos(default_datawriter_qos);
// created datawriters will use new default values
datawriter =
    publisher->create_datawriter(topic, NULL, NULL, NULL);
```

It is not safe to get or set the default QoS values for an entity while another thread may be simultaneously calling `get_default_<entity>_qos()`, `set_default_<entity>_qos()`, or `create_<entity>()` with `DDS_<ENTITY>_QOS_DEFAULT` as the `qos` parameter (for the same entity).

Another way to make QoS changes is by using XML resources (files, strings). For more information, see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

## 49.2 Setting QoS During Entity Creation

If you only want to change a QoSPolicy for a particular entity, you can pass in the desired QoS Policies for an entity in its creation routine.

To customize an entity's QoS before creating it:

1. (C API Only) Initialize a QoS object with the appropriate INITIALIZER constructor.
2. Call the relevant `get_<entity>_default_qos()` method.
3. Modify the QoS values as desired.
4. Create the entity.

For example, to change the RELIABLE QoSPolicy for a *DataWriter* before creating it:

```
// Initialize the QoS object
DDS_DataWriterQos datawriter_qos;
// Get the default values
publisher->get_default_datawriter_qos(datawriter_qos);
// Modify the QoS values as desired
datawriter_qos.reliability.kind = DDS_BEST_EFFORT_RELIABILITY_QOS;
// Create the DataWriter with new values
datawriter = publisher->create_datawriter(
    topic, datawriter_qos, NULL, NULL);
```

Another way to set QoS during entity creation is by using a QoS profile. For more information, see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

## 49.3 Changing the QoS for an Existing Entity

Some policies can also be changed after the entity has been created. To change such a policy after the entity has been created, use the entity's `set_qos()` operation.

For example, suppose you want to tweak the DEADLINE QoS for an existing *DataWriter*:

```
DDS_DataWriterQos datawriter_qos;
// get the current values
datawriter->get_qos(datawriter_qos);
// make desired changes
datawriter_qos.deadline.period.sec = 3;
datawriter_qos.deadline.period.nanosec = 0;
// set new values
datawriter->set_qos(datawriter_qos);
```

Another way to make QoS changes is by using a QoS profile. For more information, see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

**Note:** In the code examples presented in this section, we are not testing for the return code for the `set_qos()`, `set_default_*_qos()` functions. If the values used in the QoSPolicy structures are inconsistent then the functions will fail and return `INCONSISTENT_POLICY`. In addition, `set_qos()` may return `IMMUTABLE_POLICY` if you try to change a QoSPolicy on an *Entity* after that policy has become immutable. *User code should test for and address those anomalous conditions.*

## 49.4 Default QoS Values

*Connex* provides special constants for each *Entity* type that can be used in `set_qos()` and `set_default_*_qos()` to reset the QoSPolicy values to the original DDS default values:

- `DDS_PARTICIPANT_QOS_DEFAULT`
- `DDS_PUBLISHER_QOS_DEFAULT`
- `DDS_SUBSCRIBER_QOS_DEFAULT`

- DDS\_DATAWRITER\_QOS\_DEFAULT
- DDS\_DATAREADER\_QOS\_DEFAULT
- DDS\_TOPIC\_QOS\_DEFAULT

For example, if you want to set a *DataWriter's* QoS back to their DDS-specified default values:

```
datawriter->set_qos(DDS_DATAWRITER_QOS_DEFAULT);
```

Or if you want to reset the default QoS Policies used by a *Publisher* to create *DataWriters* back to their DDS-specified default values:

```
publisher->set_default_datawriter_qos(DDS_DATAWRITER_QOS_DEFAULT);
```

These defaults *cannot* be used to initialize a QoS structure for an entity. For example, the following is NOT allowed:

```
DataWriterQos dataWriterQos = DATAWRITER_QOS_DEFAULT;  
// modify QoS...  
create_datawriter(dataWriterQos);
```

# Chapter 50 Configuring QoS with XML

*Connex* entities are configured by means of Quality of Service (QoS) policies, which may be set programmatically in one of the following ways:

- Directly when the entity is created as an additional argument to the `create_<entity>()` operation (or the Entity's constructor in the Modern C++ API).
- Directly via the `set_qos()` operation on the entity.
- Indirectly as a default QoS on the factory for the entity (`set_default_<entity>_qos()` operations on *Publisher*, *Subscriber*, *DomainParticipant*, *DomainParticipantFactory*)

Entities can also be configured from an XML file or XML string. With this feature, you can change QoS configurations simply by changing the XML file or string—you do not have to recompile the application. This chapter describes how to configure *Connex* entities using XML.

## 50.1 QoS Libraries

A QoS Library is a named set of QoS profiles.

One configuration file may have several QoS libraries, each one defining its own QoS profiles.

All QoS libraries must be declared within `<dds>` and `</dds>` tags. For example:

```
<dds>
  <qos_library name="RTILibrary">
    <!-- Individual QoSs are shortcuts
         for QoS Profiles with 1 QoS -->
    <datawriter_qos name="KeepAllWriter">
      <history>
        <kind>KEEP_ALL_HISTORY_QOS</kind>
      </history>
    </datawriter_qos>
    <!-- Qos Profile -->
    <qos_profile name=
      "StrictReliableCommunicationProfile">
      <datawriter_qos>
```

```

    <history>
      <kind>KEEP_ALL_HISTORY_QOS</kind>
    </history>
    <reliability>
      <kind>RELIABLE_RELIABILITY_QOS</kind>
    </reliability>
  </datawriter_qos>
<datareader_qos>
  <history>
    <kind>KEEP_ALL_HISTORY_QOS</kind>
  </history>
  <reliability>
    <kind>RELIABLE_RELIABILITY_QOS</kind>
  </reliability>
</datareader_qos>
</qos_profile>
</qos_library>
</dds>

```

A QoS library can be reopened within the same configuration file or across different configuration files. For example:

```

<dds>
  <qos_library name="RTILibrary">
    ...
  </qos_library>
  ...
  <qos_library name="RTILibrary">
    ...
  </qos_library>
</dds>

```

## 50.2 QoS Profiles

A QoS *Profile* groups a set of related QoS policies, by entity (e.g., <datawriter\_qos>), identified by a name. For example:

```

<qos_profile name="StrictReliableCommunicationProfile">
  <datawriter_qos>
    <history>
      <kind>KEEP_ALL_HISTORY_QOS</kind>
    </history>
    <reliability>
      <kind>RELIABLE_RELIABILITY_QOS</kind>
    </reliability>
  </datawriter_qos>
  <datareader_qos>
    <history>
      <kind>KEEP_ALL_HISTORY_QOS</kind>
    </history>
    <reliability>
      <kind>RELIABLE_RELIABILITY_QOS</kind>
    </reliability>
  </datareader_qos>
</qos_profile>

```

Duplicate QoS profiles are not allowed. To overwrite a QoS profile, use [50.2.3 QoS Profile Inheritance and Composition on page 910](#).

There are functions that allow you to create *Entities* using profiles, such as `create_participant_with_profile()` ([16.3.1 Creating a DomainParticipant on page 87](#)), `create_topic_with_profile()` ([18.1.1 Creating Topics on page 248](#)), etc.

If you create an entity using a profile without a QoS definition or an inherited QoS definition (see [50.2.3 QoS Profile Inheritance and Composition on page 910](#)) for that class of entity, *Connex*t uses the default QoS.

### Example 1:

```
<qos_profile name=
"BatchStrictReliableCommunicationProfile"
base_name="StrictReliableCommunicationProfile">
  <datawriter_qos>
    <batch>
      <enable>true</enable>
    </batch>
  </datawriter_qos>
</qos_profile>
```

The *DataReader* QoS value in the profile **BatchStrictReliableCommunicationProfile** is inherited from the profile **StrictReliableCommunicationProfile**.

### Example 2:

```
<qos_profile name="BatchProfile">
  <datawriter_qos>
    <batch>
      <enable>true</enable>
    </batch>
  </datawriter_qos>
</qos_profile>
```

The *DataReader* QoS value in the profile **BatchProfile** is the default *Connex*t QoS.

## 50.2.1 Built-in QoS Profiles

Several QoS Profiles are built into the *Connex*t core libraries and can be used as starting points when configuring QoS for your *Connex*t applications. There are two provided libraries, **BuiltinQoSLib** and **BuiltinQoSLibExp**, which contain different profiles. You can use any of these profiles as base profiles when creating your own XML configurations or simply use these profiles directly in the `DDS_*_create_*_with_profile()` APIs. There is also a **BuiltinQoSSnippetLib** library, which contains profile "snippets" that can be overlaid upon the profiles to provide additional modifications to your QoS. See [50.2.3.3 QoS Profile Composition on page 914](#) for more information.

There are three types of built-in profiles:

- **Baseline.X.X.X** profiles represent the QoS defaults for *Connex* version X.X.X. The defaults for the latest *Connex* version can be accessed using the **BuiltinQosLib::Baseline** profile.
- **Generic.X** profiles allow you to easily configure different features and communication use-cases with *Connex*. For example, there is a **Generic.StrictReliable** profile for use when your application has a requirement for no data loss, regardless of the application domain.
- **Pattern.X** profiles inherit from **Generic.X** profiles and allow you to configure various domain-specific communication use cases. For example, there is a **Pattern.Alarm** profile that can be used to manage the generation and consumption of alarm events.

The **USER\_QOS\_PROFILES.xml** file generated by *RTI Code Generator* contains a profile that inherits from the **BuiltinQosLibExp::Generic.StrictReliable** profile as an example of how to use these profiles in your own application.

Example use-cases for these profiles:

- To quickly enable *RTI Monitoring Library* by inheriting from the **BuiltinQosLib::Generic.Monitoring.Common** profile. (See note below.)
- To easily revert to the default QoS values from a previous *Connex* version by inheriting from the correct **BuiltinQosLib::Baseline.X.X.X** profile.
- To set up common use-case configurations and patterns such as strict reliability or large data communication by inheriting from one of the **BuiltinQosLibExp::Generic.X** or **Pattern.X** profiles.

To see the contents of the built-in QoS profiles:

In `<NDDSHOME>/resource/xml`, you will find:

- **BaselineRoot.documentationONLY.xml**—This file contains the root baseline QoS profile corresponding to the default values of *Connex* 5.0.0.
- **BuiltinProfiles.documentationONLY.xml**—This file contains the rest of the built-in QoS profiles.

#### Notes:

- The built-in QoS profiles that enable *RTI Monitoring Library* set the property **rti-monitor.create\_function**. Consequently, they only work in *Connex* applications in which the monitoring library can be loaded dynamically. Specifically, the built-in monitoring profiles will not work when the *Connex* application links the monitoring libraries statically.

For more information, see [Chapter 59 RTI Monitoring Library](#) on page 1126.

- Some of the built-in profiles are experimental. All the experimental profiles are contained within the library **BuiltinQosLibExp**.

## 50.2.2 Overwriting Default QoS Values

There are two ways to overwrite the default QoS used for new entities with values from a profile: programmatically and with an XML attribute.

- You can overwrite the default QoS programmatically with **set\_default\_<entity>\_qos\_with\_profile()** (where <entity> is participant, topic, publisher, subscriber, datawriter, or datareader)
- You can overwrite the default QoS using the XML attribute **is\_default\_qos** with the **<qos\_profile>** tag
- Only for the DomainParticipantFactory: You can overwrite the default QoS using the XML attribute **is\_default\_participant\_factory\_profile**. This attribute has precedence over **is\_default\_qos** if both are set.

In the following example, the *DataWriter* and *DataReader* default QoS will be overwritten with the values specified in a profile named ‘**StrictReliableCommunicationProfile**’:

```
<qos_profile name="StrictReliableCommunicationProfile"
  is_default_qos="true">
  <datawriter_qos>
    <history>
      <kind>KEEP_ALL_HISTORY_QOS</kind>
    </history>
    <reliability>
      <kind>RELIABLE_RELIABILITY_QOS</kind>
    </reliability>
  </datawriter_qos>
  <datareader_qos>
    <history>
      <kind>KEEP_ALL_HISTORY_QOS</kind>
    </history>
    <reliability>
      <kind>RELIABLE_RELIABILITY_QOS</kind>
    </reliability>
  </datareader_qos>
</qos_profile>
```

If multiple profiles are configured to overwrite the default QoS, only the last one parsed applies.

### Example:

In this example, the profile used to configure the default QoSs will be **StrictReliableCommunicationProfile**.

```
<qos_profile name="BestEffortCommunicationProfile"
  is_default_qos="true">
  ...
</qos_profile>
```

```
<qos_profile name="StrictReliableCommunicationProfile"
  is_default_qos="true">
  ...
</qos_profile>
```

## 50.2.3 QoS Profile Inheritance and Composition

An individual QoS Profile or Entity QoS (e.g., `<datawriter_qos>`) can *inherit* values from other QoS Profiles, and/or be *composed* out of QoS Snippets. In inheritance, a **base\_name** attribute is used to inherit from a single, previously loaded QoS Profile. With composition, a `<base_name>` tag is used to specify a list of one or more QoS Snippets to overlay upon the base profile, creating a new composed profile. The following sections describe how these methods can be used, including best practices. See also [50.6 XML File Syntax on page 942](#).

### 50.2.3.1 QoS Profile Inheritance

An individual QoS Profile can inherit values from other QoS Profiles described in the XML file by using the attribute **base\_name**.

A QoS Profile may also inherit values from other QoS Profiles described in *different* XML files. A QoS Profile can only inherit from other QoS Profiles that have already been loaded. The order in which XML resources are loaded is described in [50.5 How to Load XML-Specified QoS Settings on page 939](#).

The following examples show how to inherit from other profiles:

#### Inheritance Example 1:

```
<qos_library name="Library">
  <qos_profile name="BaseProfile">
    <datawriter_qos>
      ...
    </datawriter_qos>
    <datareader_qos>
      ...
    </datareader_qos>
  </qos_profile>

  <!-- use the base_name attribute to inherit from another profile -->
  <qos_profile name="DerivedProfile" base_name="BaseProfile">
    <datawriter_qos>
      <batch>
        <enable>true</enable>
        <max_samples>100</max_samples>
        <max_data_bytes>LENGTH_UNLIMITED</max_data_bytes>
      </batch>
    </datawriter_qos>
    <datareader_qos>
      ...
    </datareader_qos>
```

```
</qos_profile>
</qos_library>
```

In this example, the QoS Profile called `DerivedProfile` is constructed via inheritance from the QoS Profile `BaseProfile`. The profile `DerivedProfile` inherits `BaseProfile` by referencing the base profile in the `qos_profile` attribute `base_name="BaseProfile"`. This means that the `datawriter_qos` and `datareader_qos` in `DerivedProfile` inherit their values from the corresponding `datawriter_qos` and `datareader_qos` in `BaseProfile`. The QoS Profile `DerivedProfile` first initializes all its QoS policies with the values obtained from `BaseProfile`. Then it applies any QoS policies explicitly listed in its own definition to override the initialized values. In this example, `MyDerivedProfile` only modifies the `BatchQos` policy on the `DataWriter` QoS.

If a QoS Profile definition does not specify the `base_name` attribute, then it is initialized from the builtin defaults provided by *Connex*. See [50.2.1 Built-in QoS Profiles on page 907](#).

### Inheritance Example 2:

```
<qos_library name="Library">
  <datareader_qos name="BaseProfile">
    ...
  </datareader_qos>
  <datareader_qos name="DerivedProfile" base_name="BaseProfile">
    ...
  </datareader_qos>
</qos_library>
```

The `datareader_qos` in `DerivedProfile` inherits its values from the `datareader_qos` of `BaseProfile`. In this example, the `datareader_qos` definition is a shortcut for a QoS Profile definition with a single QoS.

### Inheritance Example 3:

```
<qos_library name="Library">
  <qos_profile name="Profile1">
    <datawriter_qos name="BaseWriterQoS">
      ...
    </datawriter_qos>
    <datareader_qos>
      ...
    </datareader_qos>
  </qos_profile>
  <qos_profile name="Profile2">
    <datawriter_qos name="DerivedWriterQoS" base_name="Profile1::BaseWriterQoS">
      ...
    </datawriter_qos>
    <datareader_qos>
      ...
    </datareader_qos>
  </qos_profile>
</qos_library>
```

The `datawriter_qos` in `Profile2` inherits its values from the `datawriter_qos` in `Profile1`. The `datareader_qos` in `Profile2` will not inherit the values from the corresponding QoS in `Profile1`. Since `Profile2` doesn't inherit from any other QoS Profile, the `datareader_qos` values will be taken from the builtin defaults. See [50.2.1 Built-in QoS Profiles on page 907](#).

**Inheritance Example 4:**

```

<qos_library name="Library">
  <qos_profile name="Profile1">
    <datawriter_qos>
      ...
    </datawriter_qos>
    <datareader_qos>
      ...
    </datareader_qos>
  </qos_profile>
  <qos_profile name="Profile2">
    <datawriter_qos name="BaseWriterQoS">
      ...
    </datawriter_qos>
    <datareader_qos>
      ...
    </datareader_qos>
  </qos_profile>
  <qos_profile name="Profile3" base_name="Profile1">
    <datawriter_qos name="DerivedWriterQoS" base_name="Profile2::BaseWriterQoS">
      ...
    </datawriter_qos>
    <datareader_qos>
      ...
    </datareader_qos>
  </qos_profile>
</qos_library>

```

The `datawriter_qos` in Profile3 inherits its values from the `datawriter_qos` in Profile2. The `datareader_qos` in Profile3 inherits its values from the `datareader_qos` in Profile1.

**Inheritance Example 5:**

```

<qos_library name="Library">
  <datareader_qos name="BaseProfile">
    ...
  </datareader_qos>
  <profile name="DerivedProfile" base_name="BaseProfile">
    <datareader_qos>
      ...
    </datareader_qos>
  </profile>
</qos_library>

```

The `datareader_qos` in DerivedProfile inherits its values from the `datareader_qos` in BaseProfile.

**Inheritance Example 6:**

Global\_QoS.xml

```

<qos_library name="GlobalLibrary">
  <qos_profile name="GlobalProfileA">
    </qos_profile>
  </qos_library>

```

## Component\_QoS.xml

```
<qos_library name="ComponentLibrary">
  <qos_profile name="ComponentProfileA" basename="GlobalLibrary::GlobalProfileA">
    </qos_profile
  </qos_library>
```

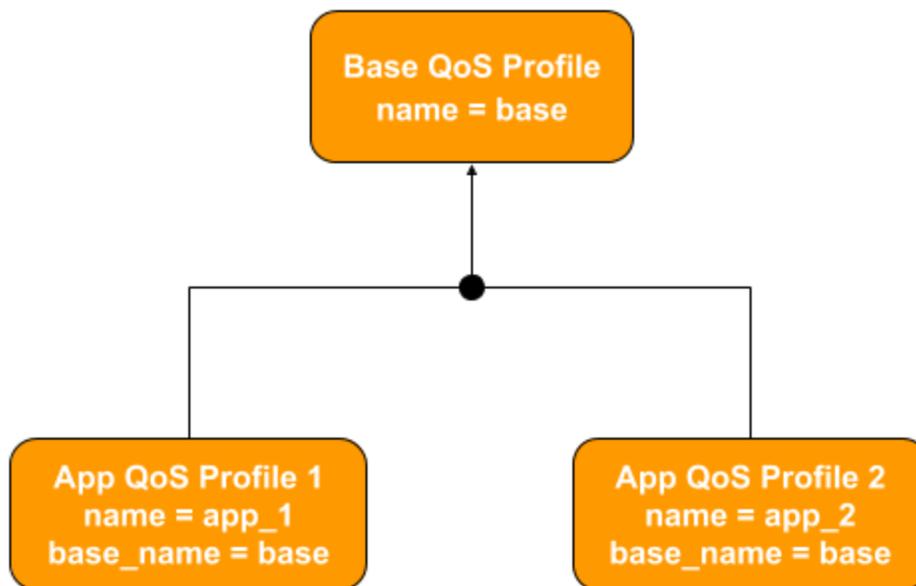

Previous examples show that a QoS Profile or QoS can inherit values from other QoS Profiles or QoSes, which should already be loaded. In this example, a QoS Profile inherits values from another QoS Profile defined in a separate QoS Library, in another file. This is a typical use case where QoSes are constructed by separating them into multiple files. In this example, Global\_QoS.xml has to be loaded before Component\_QoS.xml.

To learn more about how to load multiple files in your application, see [50.5 How to Load XML-Specified QoS Settings on page 939](#).

## 50.2.3.2 Limitations of QoS Profile Inheritance

While useful, initializing a QoS Profile from a single base QoS Profile can also be limiting. For example, assume you have the configuration shown in [Figure 50.1: Single Inheritance Example below](#)

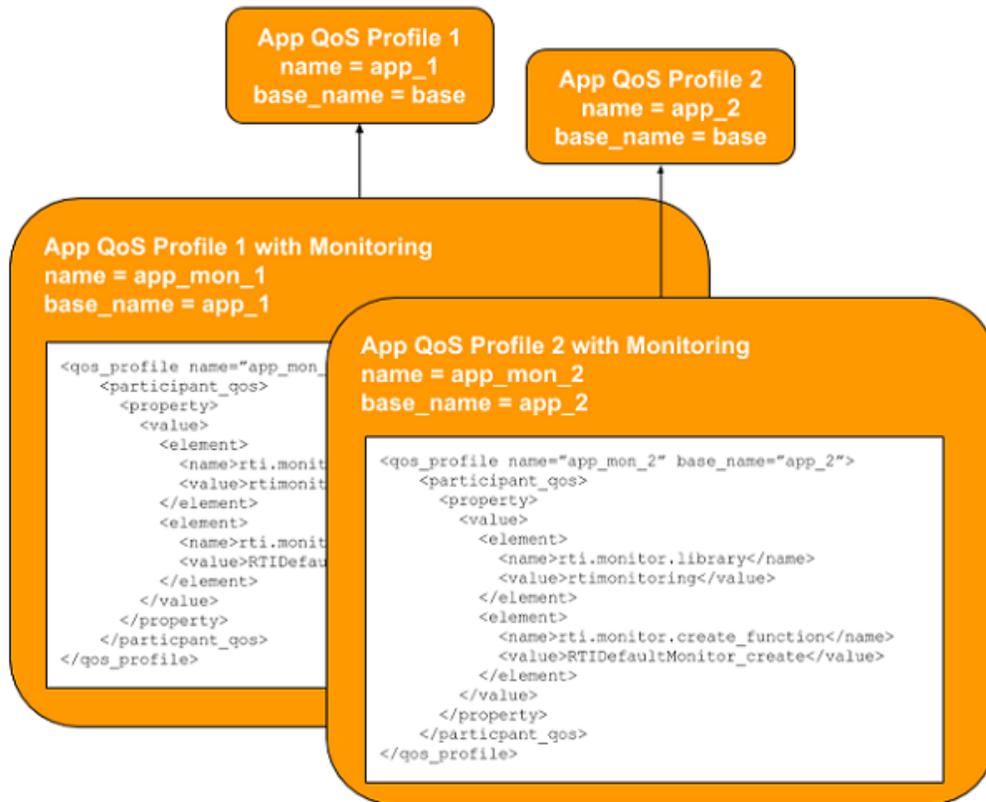

**Figure 50.1: Single Inheritance Example**

If you wanted to incorporate monitoring into the QoS Profiles app\_1 and app\_2, the only option with inheritance would be to create two new QoS Profiles, each inheriting from app\_1 and app\_2 respectively, and to copy the monitoring XML configuration into each of the two new QoS Profiles as shown

in [Figure 50.2: Duplication of Configuration in Inheritance below](#). This results in significant XML code duplication and leads to maintainability issues.

Figure 50.2: Duplication of Configuration in Inheritance

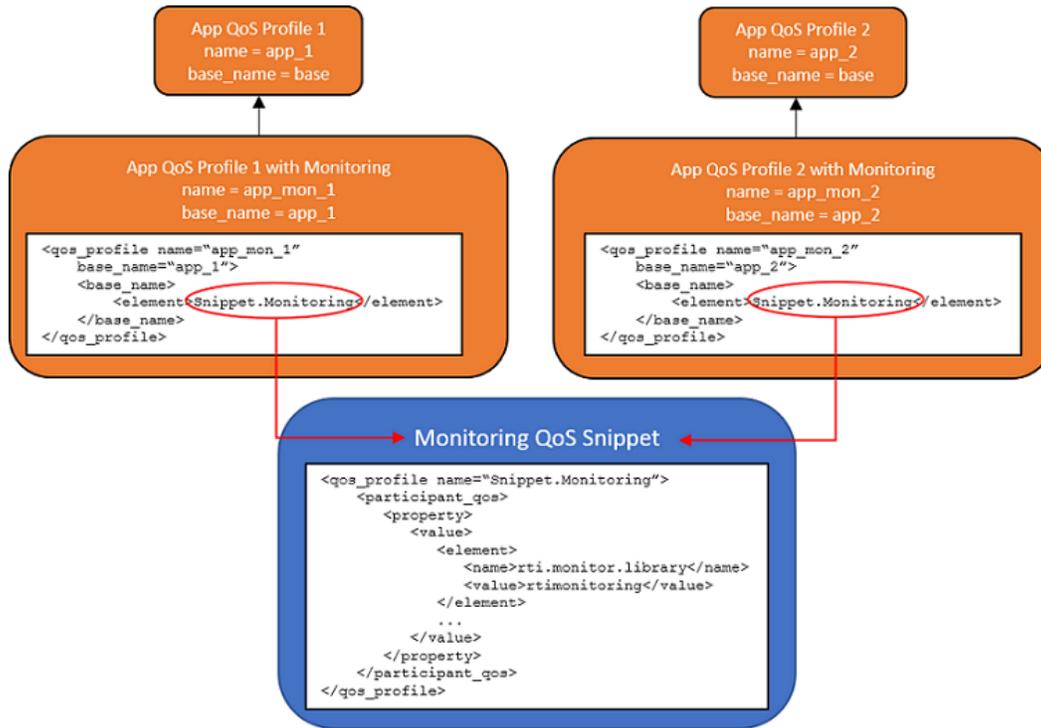

The following section describes how to handle the above scenario using QoS Profile *composition*.

### 50.2.3.3 QoS Profile Composition

QoS Profile composition uses QoS *Snippets* to more easily update profiles that you use or inherit. QoS Snippets are small pieces of well-formed, reusable XML QoS that configure a single aspect of QoS, such as enabling monitoring or security.

In the previous example, you could add the monitoring configuration to the new QoS Profiles app\_mon\_1 and app\_mon\_2 by referring to a QoS Snippet that configures monitoring.

Figure 50.3: One Reusable Configuration Snippet

QoS Snippets are intended to be composed into other QoS Snippets and QoS Profiles. As shown in the example below, the syntax used to define a QoS Snippet is the same as that of a QoS Profile, *but the intent and usage are different*.

The following is an example of the syntax used to define and use QoS Snippets.

### Composition Example 1:

```

<!-- This is a QoS Snippet -->
<qos_profile name="Snippet1">
  <datareader_qos>
    <reliability>
      <kind>RELIABLE_RELIABILITY</kind>
    </reliability>
  </datareader_qos>
</qos_profile>

<!-- This is a QoS Snippet -->
<qos_profile name="Snippet2">
  <datareader_qos>
    <durability>
      <kind>TRANSIENT_LOCAL_DURABILITY</kind>
    </durability>
  </datareader_qos>
</qos_profile>

<qos_profile name="Profile1">

```

```

    <datawriter_qos>
      <publication_name>
        <name>SampleDataWriter_A</name>
      </publication_name>
    </datawriter_qos>
  </qos_profile>

<!-- This QoS Profile definition uses the Snippets -->
  <qos_profile name="MyDerivedAndComposedProfile" base_name="Profile1">
    <base_name>
      <element>Snippet1</element>
      <element>Snippet2</element>
    </base_name>
    <datareader_qos>
      <history>
        <kind>KEEP_LAST_HISTORY_QOS</kind>
        <depth>6</depth>
      </history>
    </datareader_qos>
  </qos_profile>

```

In this example, a QoS Profile inherits from another QoS Profile and uses composition to weave in policies from two QoS Snippets. Specifically, `MyDerivedAndComposedProfile` is constructed by inheriting from `Profile1`, then by overlaying `Snippet1` and `Snippet2`. Finally, `MyDerivedAndComposedProfile` applies its own QoS policies, which overwrite any others. See also [50.2.3.3.2 Order and Precedence of Inheritance on the next page](#).

It is recommended to use fully qualified names in the element tag if there is ambiguity in the QoS Profile or QoS Snippet names you have loaded in your application.

#### 50.2.3.3.1 How Inheritance and Composition Work Together

The process of inheriting QoS Profiles and composing from QoS Snippets works as follows:

1. The QoS policies are initialized from those in the base profile, using the **base\_name** attribute of the **<qos\_profile>** tag. If the **base\_name** attribute is not present, then the policies are initialized from the builtin defaults defined by *Connex*.
2. The policies are overridden with those defined in the QoS Snippets listed inside the **<base\_name>** XML tag. The QoS Snippets are applied in the order in which they appear. So the first QoS Snippet (`Snippet1` in the example above) overrides the policies that were set from the inherited base QoS Profile (`Profile1` in the example), the second QoS Snippet (`Snippet2` in the example) overrides whatever was the result of applying `Snippet1`, and so on.
3. The policies that appear explicitly as elements in the QoS Profile are applied. These override the policies set by the base QoS Profile and the QoS Snippets. In this example, a `KEEP_LAST_HISTORY_DEPTH` of 6 overrides whatever was set by the base QoS Profile and the QoS Snippets.

You *inherit* a QoS Profile, but *overlay* one or more QoS Snippets. *Inherit* a QoS Profile because you want to subsume the complete definition of the QoS policies for a particular use case. *Overlay* QoS Snippets onto a QoS Profile so that you override only a single aspect of QoS: for instance, only what is logically associated with monitoring.

### 50.2.3.3.2 Order and Precedence of Inheritance

Values are inherited from the specified elements in the `<base_name>` tag, in order from top to bottom. Values inherited from elements lower in the order (Snippet2 in the examples) will overwrite the same values (if present) from elements higher up (Snippet1 in the examples). Remember that the QoS, QoS Profile, or QoS Snippet should already be loaded as a part of your XML file. (See [50.5 How to Load XML-Specified QoS Settings on page 939](#).)

In the following example, MyDerivedAndComposedProfile inherits from Profile1, keeping Profile1's SampleDataWriter\_A but getting `<durability>` and `<reliability>` from the Snippets rather than from Profile1. Finally, MyDerivedAndComposedProfile applies its own local `<history>` policies.

### Composition Example 2:

```

<!-- This is a QoS Snippet -->
  <qos_profile name="Snippet1">
    <datareader_qos>
      <reliability>
        <kind>RELIABLE_RELIABILITY_QOS</kind>
      </reliability>
    </datareader_qos>
  </qos_profile>

<!-- This is a QoS Snippet -->
  <qos_profile name="Snippet2">
    <datareader_qos>
      <durability>
        <kind>TRANSIENT_LOCAL_DURABILITY_QOS</kind>
      </durability>
    </datareader_qos>
  </qos_profile>

  <qos_profile name="Profile1">
    <datawriter_qos>
      <publication_name>
        <name>SampleDataWriter_A</name>
      </publication_name>
    </datawriter_qos>
    <datareader_qos>
      <durability>
        <kind>VOLATILE_DURABILITY_QOS</kind>
      </durability>
      <reliability>
        <kind>BEST_EFFORT_RELIABILITY_QOS</kind>
      </reliability>
    </datareader_qos>
  </qos_profile>

```

```

</qos_profile>

<!-- This QoS Profile definition uses the Snippets -->
<qos_profile name="MyDerivedAndComposedProfile" base_name="Profile1">
  <base_name>
    <element>Snippet1</element>
    <element>Snippet2</element>
  </base_name>
  <datareader_qos>
    <history>
      <kind>KEEP_LAST_HISTORY_QOS</kind>
      <depth>6</depth>
    </history>
  </datareader_qos>
</qos_profile>

```

The final values in MyDerivedAndComposedProfile will be as follows (map the colors in the example to what actually gets used), as shown here:

```

<qos_profile name="MyDerivedAndComposedProfile">
  <datareader_qos>
    <reliability>
      <kind>RELIABLE_RELIABILITY</kind>
    </reliability>
    <history>
      <kind>KEEP_LAST_HISTORY_QOS</kind>
      <depth>6</depth>
    </history>
    <durability>
      <kind>TRANSIENT_LOCAL_DURABILITY</kind>
    </durability>
  </datareader_qos>
  <datawriter_qos>
    <publication_name>
      <name>SampleDataWriter_A</name>
    </publication_name>
  </datawriter_qos>
</qos_profile>

```

### Composition Example 3

Imagine that Example 2 had the following Snippets instead:

```

<!-- This is a QoS Snippet -->
<qos_profile name="Snippet1">
  <datawriter_qos>
    <reliability>
      <kind>RELIABLE_RELIABILITY_QOS</kind>
      <max_blocking_time>
        <sec>5</sec>
        <nanosec>0</nanosec>
      </max_blocking_time>
    </reliability>
  </datawriter_qos>

```

```

</qos_profile>

<!-- This is a QoS Snippet -->
  <qos_profile name="Snippet2">
    <datawriter_qos>
      <reliability>
        <kind>RELIABLE_RELIABILITY_QOS</kind>
        <max_blocking_time>
          <nanosec>1000000</nanosec>
        </max_blocking_time>
      </reliability>
    </datawriter_qos>
  </qos_profile>

<!-- This QoS Profile definition uses the Snippets -->
  <qos_profile name="MyDerivedAndComposedProfile" base_name="Profile1">
    <base_name>
      <element>Snippet1</element>
      <element>Snippet2</element>
    </base_name>
  </qos_profile>

```

In this example, Snippet2's **nanosec** overwrites Snippet1's. But since Snippet2 does not specify a **sec**, Snippet1's **sec** is used. The resultant QoS is a combination of the two **reliability** policies:

```

<!-- The above example combines the reliability settings because one QoS Snippet is overlaid
on the other -->
  <reliability>
    <kind>RELIABLE_RELIABILITY_QOS</kind>
    <max_blocking_time>
      <sec>5</sec>
      <nanosec>1000000</nanosec>
    </max_blocking_time>
  </reliability>

```

Imagine now that the QoS Snippets in the above example were reversed, and Snippet2 was listed first in the file. Snippet2 would apply a **nanosec** of 1000000; then Snippet1 would overwrite that with 0 and apply its **sec** of 5. The result would be a **max\_blocking\_time** of 5 seconds and 0 nanoseconds.

You can use the **rtxmloutpututility** utility to see what the final QoS values will be in your system when composition and inheritance complete their derivations. See [50.2.3.6 Viewing Resolved QoS Values on page 925](#).

#### Composition Example 4:

If you specify **<base\_name>** for a QoS Profile and also specify **<base\_name>** for a QoS within it, the **<base\_name>** tag or attribute in the QoS will take precedence. That is, **<base\_name>** from the QoS Profile will be ignored for the QoS specifying its own **<base\_name>**.

The following example illustrates this concept:

```

<dds>
  <qos_library>

```

```

<qos_profile name="ParentProfile">
  <base_name>
    <element>A</element>
    <element>B</element>
  </base_name>
  ...
  <datawriter_qos name="DW_QoS">
    <base_name>
      <element>C</element>
      <element>D</element>
    </base_name>
  </datawriter_qos>
</qos_profile>
</qos_library>
</dds>

```

In this example, since DW\_QoS has its own list for the **<base\_name>** tag, DW\_QoS will only inherit values from C and D. It will NOT inherit anything from A and B specified as a part of ParentProfile, since its own **<base\_name>** tag overrides it.

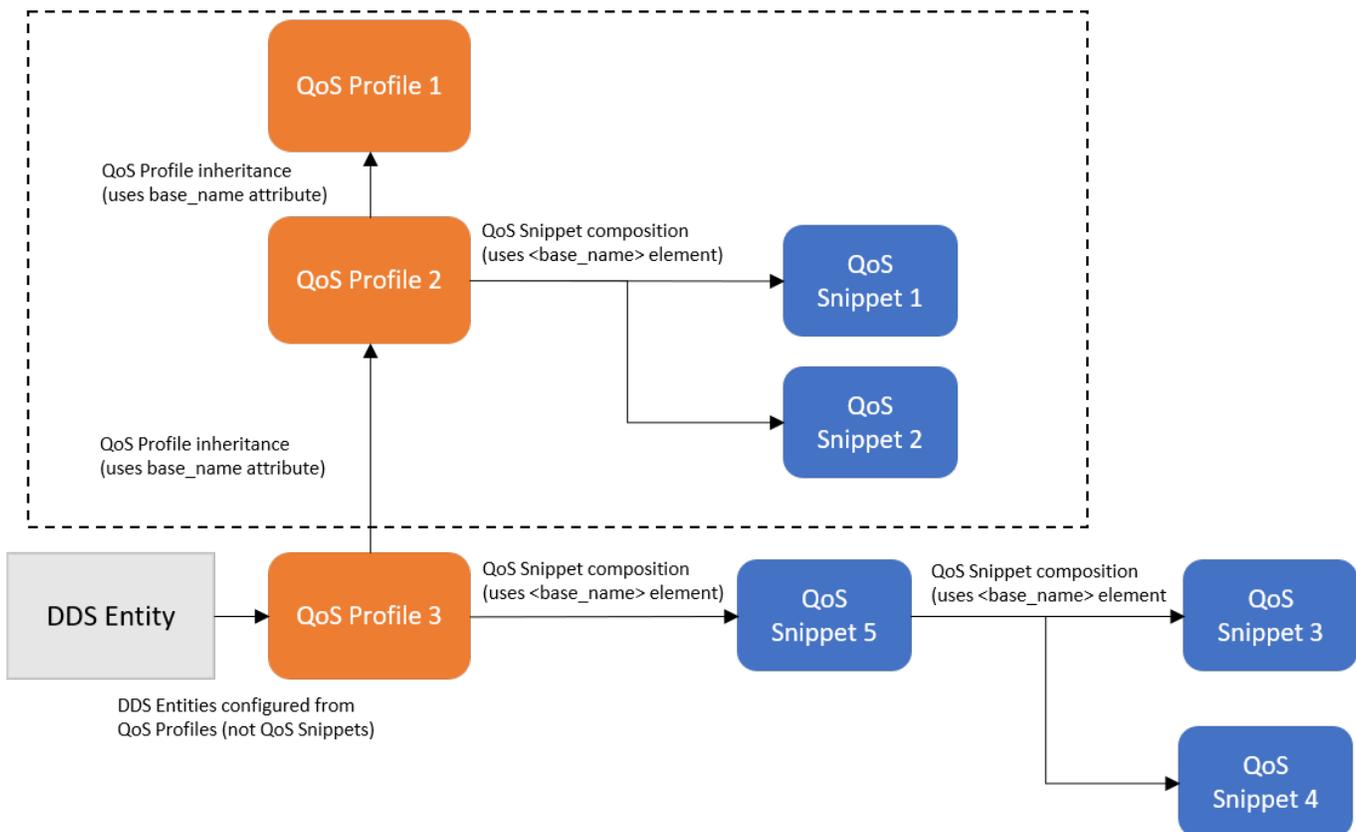

#### 50.2.3.4 Best Practices for Inheritance and Composition

XML QoS Profile inheritance and composition provide a powerful way to define configurations, allowing flexibility and reusability. It is important to understand the underlying mechanics and follow the best practices described below to maximize usability and avoid unexpected results.

- *Differentiate between QoS Profiles and QoS Snippets.*
  - Think of QoS Profiles as complete definitions of all QoS policies for a particular use case. Construct QoS Profiles so that all aspects of the use case are covered.
  - Think of QoS Snippets as small, generic, orthogonal chunks of QoS policies. Construct QoS Snippets to configure a single aspect of a configuration, such as monitoring or security.
- *Use QoS Profiles for inheritance only, never composition.* Use a QoS Profile in a **base\_name** attribute, never inside a **<base\_name>** element.
- *Use QoS Snippets for composition, never inheritance.* Use a QoS Snippet inside a **<base\_name>** element, never in a **base\_name** attribute.
- *Use QoS Profiles, not QoS Snippets, to create DDS Entities.* Do not pass a QoS Snippet name to the DDS operations **create\_<entity>\_with\_profile()**, **get\_<entity>\_qos\_from\_profile()**, **set\_qos\_with\_profile()**, or **set\_default\_profile()**.
- *Keep QoS Snippets generic and reusable.* Never use the **<topic\_filter>** element in a QoS Snippet.

These best practices are illustrated in the following figure and further described in the sections that follow.

Figure 50.4: Best Practices for Inheritance and Composition

In [Figure 50.4: Best Practices for Inheritance and Composition](#) above, imagine the results produced by the dotted box, as already illustrated in the previous examples. These results are inherited by QoS Profile 3. QoS Profile 3's snippets are then applied. (QoS Snippet 5 inherits from two other snippets first.) Finally, any policies in QoS Profile 3 that differ from the results produced by the inheritance from profiles 1 and 2 are applied.

Another way to look at [Figure 50.4: Best Practices for Inheritance and Composition](#) above is as a tree whose nodes are applied in this order, where "QP" refers to the QoS Profiles in the figure and "QS" refers to the QoS Snippets in the figure:

1. QP1 (because inheritance says we start all the way back at the first inherited profile)
2. QS1, then QS2 (because snippets are overlaid next)
3. QP2 (because it may have deltas that overwrite what has been composed so far)
4. QS3, then QS4 (because QS5 inherits from QS3 and QS4 first)
5. QS5 (because it may have deltas that overwrite QS3 and QS4)
6. QP3 (because it may have deltas that overwrite everything composed so far)

#### 50.2.3.4.1 Differentiate between QoS Profiles and QoS Snippets

When defining a QoS Profile, decide whether you are:

- Creating a QoS Profile intended to create DDS *Entities* and/or fully define their QoS.
- Creating a QoS Snippet intended as a reusable block to be composed in the definition of QoS Profiles and other QoS Snippets.

These two options are fundamentally different.

A QoS Profile is intended to define the QoS policies used to create a DDS *Entity*. Therefore, it should match a specific application use case (e.g., sending alarms or streaming periodic data). Moreover, because the QoS Profile will be used to create a DDS *Entity*, it implicitly defines values for all the QoS Policies that apply to the entity.

When defining a QoS Profile, choose the builtin QoS Profile that most closely matches your use case. Use that builtin QoS Profile as a base profile. For example:

```
<qos_profile name="MyProfile" base_name="BuiltinQosLibExp::Pattern.AlarmEvent">
  <!-- modify the profile by composing with QoS Snippets -->
  <!-- modify the profile by overriding the QoS policies explicitly -->
</qos_profile>
```

Give the QoS Profile a name that makes clear its intended use, as well as the fact that it is a QoS Profile (instead of a QoS Snippet). For example, use “Profile” as a suffix in the name of the QoS Profile or some other consistent naming convention.

A QoS Snippet is intended as a generic block of QoS policies for composition into QoS Profiles and other QoS Snippets. For example, configuring monitoring, configuring Security, and configuring a FlowController are good uses for QoS Snippets.

QoS Snippets should focus on a single aspect of QoS policy and try not to set unrelated policies. This maximizes composability, avoiding interfering with policies set by other QoS Snippets.

QoS Snippets should be generic and reusable across systems and deployments. Therefore, it does not make sense to constrain their applicability using the `<topic_filter>` element within their definition. Doing so may also result in conflict with topic filters set on QoS Profiles that use those QoS Snippets.

Give the QoS Snippet a name that makes clear its intended use, as well as the fact that it is a QoS Snippet (not a regular QoS Profile). For example, use “Snippet” as a suffix in the name of the QoS Snippet or some other consistent naming convention.

#### 50.2.3.4.2 Use QoS Profiles for inheritance only, never composition

Aside from its use for creating DDS *Entities*, a QoS Profile may be used as the base definition of another QoS Profile. For example:

```
<qos_profile name="MyDerivedProfile" base_name="MyBaseProfile">
  ...
```

```
</qos_profile>
```

When used for inheritance, the derived profile is initialized with the policies of the base profile.

A profile should never be used for composition. That is, it should not be referenced within the **<base\_name>** element:

```
<qos_profile name="MyDerivedProfile">
  <base_name>
    <element>MyBaseProfile</element> <!-- never do this -->
  </base_name>
</qos_profile>
```

Because a QoS Profile implicitly defines all the QoS policies, using it for composition would have the unintended effect of potentially overriding all the policies.

#### 50.2.3.4.3 Use QoS Snippets for composition, never inheritance

QoS Snippets are small pieces of well-formed XML QoS intended to configure a single aspect of a QoS. The proper way to use them is for the composition of other QoS Profiles and QoS Snippets. Therefore, they must only appear within the **<base\_name>** tag "element." For example:

```
<qos_profile name="MyComposedProfile" base_name="MyBaseProfile">
  <base_name>
    <element>Snippet1</element>
    <element>Snippet2</element>
    <element>Snippet3</element>
  </base_name>
  ...
</qos_profile>

<qos_profile name="MyComposedSnippet">
  <base_name>
    <element>Snippet1</element>
    <element>Snippet2</element>
    <element>Snippet3</element>
  </base_name>
  ...
</qos_profile>
```

Do not use a QoS Snippet for inheritance. For example

```
<!-- do not do this -->
<qos_profile name="MyComposedProfile" base_name="Snippet1">
  <base_name>
    <element>Snippet2</element>
    <element>Snippet3</element>
  </base_name>
  ...
</qos_profile>
```

If you use a QoS Snippet for inheritance (i.e., for initializing another QoS Profile), you are using something that was not intended to be a full definition; thus, it may overlook the proper configuration of certain policies for your system.

#### 50.2.3.4.4 Use QoS Profiles, not QoS Snippets, to create DDS Entities

The QoS configuration of DDS *Entities* can be specified using QoS Profiles. This is a convenient mechanism that allows separation of configuration from the functional logic of your application.

The *Connex* API contains several operations that reference QoS Profiles by name, such as `create_participant_with_profile()` and `create_topic_with_profile()`. These operations are used to either create DDS *Entities* with the QoS policies referenced by the profile name, or to initialize the *Entity* QoS structure with the QoS policies referenced by the profile. Either way, these operations **should not be called using a QoS Snippet name** as the reference.

#### 50.2.3.4.5 Keep QoS Snippets generic and reusable

QoS Snippets should be developed with reuse in mind and should not use the `<topic_filter>` element within the definition of the QoS Snippet.

```
<!-- do not do this -->
<qos_profile name="MySnippet">
  <datawriter_qos topic_filter="Alarm">
    <reliability>
      <kind>RELIABLE_RELIABILITY</kind>
    </reliability>
  </datawriter_qos>
  <datawriter_qos topic_filter="SensorUpdate">
    <reliability>
      <kind>BEST_EFFORTS_RELIABILITY</kind>
    </reliability>
  </datawriter_qos>
  ...
</qos_profile>
```

The `<topic_filter>` element conditionally defines the QoS Profile depending on the *Topic* name associated with the *Entity* being created or configured. Since the QoS Snippet is not intended to create or configure DDS *Entities* directly, it does not make sense to use the `<topic_filter>` element in its definition.

#### 50.2.3.5 Enforcement of QoS Profile and QoS Snippet Conventions

*Connex* uses the same syntax for the creation of QoS Profiles and QoS Snippets. Therefore, it does not enforce the conventions described here. Although *Connex* will not detect or prevent violation of these conventions (e.g., if you use a QoS Profile for composition), following these conventions is strongly encouraged to avoid unexpected results. Furthermore, future versions of *Connex* may introduce different syntax that allows differentiating QoS Profiles from QoS Snippets and enforces the conventions. If you follow these conventions now, you can continue using them without violating future syntax.

### 50.2.3.6 Viewing Resolved QoS Values

The final value for a QoS configuration, especially when using inheritance and QoS Snippet composition, can be visualized at runtime in a variety of ways:

- Locally in your application, the QoS **to\_string** functions allow *Entity* QoS objects to be converted into strings and printed, so that you can see the current QoS being used. *Entity* QoS types are `DataReaderQos`, `DataWriterQos`, `PublisherQos`, `SubscriberQos`, `TopicQos`, `DomainParticipantQos` and `DomainParticipantFactoryQos`.
- Additionally, when an entity is created, or when the **set\_qos** operation is called on an entity, the QoS settings it is using are output to the log, if logging is configured with a verbosity of `NDDS_CONFIG_LOG_VERBOSITY_STATUS_LOCAL` and category of `NDDS_CONFIG_LOG_CATEGORY_API`. (See [54.2 Configuring Connex Logging on page 1089](#).) If the **DDS\_EntityNameQosPolicy** is set, the names will be printed as part of a header to help associate logged QoS settings with the appropriate entities. *Connex* automatically prints the QoSes of these entities to the log in XML format. Note it is not required that your QoS was configured in XML, it will always be logged in XML format to the log.

The logged QoS when using logging, or the **to\_string** functions, will show only the QoS settings that are different from the documented default (several **to\_string** overloads can override this behavior). The documented default refers to the default value of a policy as specified by the API reference HTML documentation.

- Remotely, using *RTI Monitor*.
- Remotely, using *RTI Admin Console*. Note that when visualizing the QoS using *Admin Console*, only a subset of the QoS are shown. Only QoS policies that are required for matching are propagated to *Admin Console*.

Here is an example of a **to\_string** function in the Modern C++ API:

```
using namespace rti::all;

DataWriterQos the_qos = writer_qos();

// Obtain a string representation of the DataWriterQos object
// Only differences with respect to the documented default will be included
std::string the_string = to_string(the_qos);

// Create another DataWriterQos object and change some policies
DataWriterQos other_qos;
other_qos << Reliability::BestEffort();
// The differences with respect to the other_qos object will now be stored to the string
the_string = to_string(the_qos, other_qos);

// Finally, we can print the entire QoS object (not just differences)
the_string = to_string(the_qos, rti::core::qos_print_all);
```

For older releases, or where code change/recompilation isn't possible, you can use **rtixmloutpututility** to visualize the end result of your QoS settings at entity creation time.

**rtixmloutpututility** allows you to see the final QoS values your entities will receive after inheritance and composition are resolved. Here is an example usage of this utility:

```
$ ./rtixmloutpututility
  -qosFile '/home/xxx/Documents/Tests/CORE-9446/USER_QOS_
PROFILES.xml;/home/xxx/Documents/Tests/CORE-1375/USER_QOS_PROFILES.xml'
  -profilePath Data_Library::Data_Profile
  -outputFile Dummy.txt
  -qosTag domain_participant_qos/property
```

To get this utility, including more information about its options and usage, please see: <https://github.com/rticommunity/rticonnextdds-xml-output-utility>.

## 50.2.4 Topic Filters

A QoS profile may contain several writer, reader and topic QoSs. *Connex*t will select a QoS based on the evaluation of a filter expression (as defined in the POSIX fnmatch API (1003.2-1992 Section B.6)) on the topic name. The filter expression is specified as an attribute in the XML QoS definition. For example:

```
<qos_profile name="StrictReliableCommunicationProfile">
<datawriter_qos topic_filter="A*">
  <history>
    <kind>KEEP_ALL_HISTORY_QOS</kind>
  </history>
  <reliability>
    <kind>RELIABLE_RELIABILITY_QOS</kind>
  </reliability>
</datawriter_qos>
<datawriter_qos topic_filter="B*">
  <history>
    <kind>KEEP_ALL_HISTORY_QOS</kind>
  </history>
  <reliability>
    <kind>RELIABLE_RELIABILITY_QOS</kind>
  </reliability>
  <resource_limits>
    <max_samples>128</max_samples>
    <max_samples_per_instance>128
  </max_samples_per_instance>
    <initial_samples>128</initial_samples>
    <max_instances>1</max_instances>
    <initial_instances>1</initial_instances>
  </resource_limits>
</datawriter_qos>
  ...
</qos_profile>
```

If **topic\_filter** is not specified in a QoS, *Connex*t will assume the filter '\*'. The QoSs with an explicit **topic\_filter** attribute definition will be evaluated in order; they have precedence over a QoS without a

**topic\_filter** expression.

The **topic\_filter** attribute is only used with the following APIs:

*DomainParticipantFactory:*

- **get\_<entity>\_qos\_from\_profile\_w\_topic\_name()** (where <entity> may be topic, datareader, or datareader; see [16.2.5 Getting QoS Values from a QoS Profile on page 80](#))

*DomainParticipant:*

- **create\_datawriter\_with\_profile()** (see [31.1 Creating DataWriters on page 393](#))
- **create\_datareader\_with\_profile()** (see [40.1 Creating DataReaders on page 620](#))
- **create\_topic\_with\_profile()** (see [18.1.1 Creating Topics on page 248](#))

*Publisher:*

- **create\_datawriter\_with\_profile()** (see [31.1 Creating DataWriters on page 393](#))

*Subscriber:*

- **create\_datareader\_with\_profile()** (see [40.1 Creating DataReaders on page 620](#))

*Topic:*

- **set\_qos\_with\_profile()** (see [18.1.3 Setting Topic QoS Policies on page 250](#))

*DataWriter:*

- **set\_qos\_with\_profile()** (see [30.4.3 Changing QoS Settings After the Publisher Has Been Created on page 382](#))

*DataReader:*

- **set\_qos\_with\_profile()** (see [40.9 Setting DataReader QoS Policies on page 652](#))

**Note:** in the Modern C++ API, use **dds::core::QosProvider::<entity>\_qos\_w\_topic\_name()** to obtain the QoS associated with a topic. For example:

```
auto reader_qos = qos_provider.extensions().datareader_qos_w_topic_name("Example Topic");
dds::sub::DataReader<Foo> reader(subscriber, topic, reader_qos);
```

Other APIs will ignore QoSs with a **topic\_filter** value different than "\*". A QoS Profile with QoSs using **topic\_filter** can also inherit from other QoS Profiles. In this case, inheritance will consider the value of the **topic\_filter** expression.

### Example 1:

```
<qos_library name="Library">
  <qos_profile name="BaseProfile">
    <datawriter_qos>
      ...
    </datawriter_qos>
    <datawriter_qos topic_filter="T1*">
      ...
    </datawriter_qos>
    <datawriter_qos topic_filter="T2*">
      ...
    </datawriter_qos>
  </qos_profile>
  <qos_profile name="DerivedProfile" base_name="BaseProfile">
    <datawriter_qos topic_filter="T11">
      ...
    </datawriter_qos>
    <datawriter_qos topic_filter="T21">
      ...
    </datawriter_qos>
    <datawriter_qos topic_filter="T31">
      ...
    </datawriter_qos>
  </qos_profile>
</qos_library>
```

The **datawriter\_qos** with **topic\_filter** T11 in DerivedProfile will inherit its values from the **datawriter\_qos** with **topic\_filter** T1\* in BaseProfile. The **datawriter\_qos** with **topic\_filter** T21 in DerivedProfile will inherit its values from the **datawriter\_qos** with **topic\_filter** T2\* in BaseProfile. The **datawriter\_qos** with **topic\_filter** T31 in DerivedProfile will inherit its values from the **datawriter\_qos** without **topic\_filter** in BaseProfile.

**Example 2:**

```

<qos_library name="Library">
  <qos_profile name="BaseProfile">
    <datawriter_qos topic_filter="T1*">
      ...
    </datawriter_qos>
    <datawriter_qos name="T2DataWriterQoS" topic_filter="T2*">
      ...
    </datawriter_qos>
  </qos_profile>
  <qos_profile name="DerivedProfile" base_name="BaseProfile">
    <datawriter_qos topic_filter="T11"
      base_name="BaseProfile::T2DataWriterQoS">
      ...
    </datawriter_qos>
    <datawriter_qos topic_filter="T21">
      ...
    </datawriter_qos>
  </qos_profile>
</qos_library>

```

Although the **topic\_filter** expressions do not match, the **datawriter\_qos** with **topic\_filter** T11 in DerivedProfile will inherit its values from the **datawriter\_qos** with **topic\_filter** T2\* in BaseProfile. **topic\_filter** is not used with inheritance from QoS to QoS. The **datawriter\_qos** with **topic\_filter** T21 in DerivedProfile will inherit its values from the **datawriter\_qos** with **topic\_filter** T2\* in BaseProfile.

**Example 3:**

```

<qos_library name="Library">
  <datawriter_qos name="BaseQoS" topic_filter="T1">
    ...
  </datawriter_qos>
  <datawriter_qos name="DerivedQoS" base_name="BaseQoS" topic_filter="T2">
    ...
  </datawriter_qos>
</qos_library>

```

In the case of a single QoS profile, although the **topic\_filter** expressions do not match, the **datawriter\_qos** named DerivedQoS with **topic\_filter** T2 will inherit its values from the **datawriter\_qos** named BaseQoS with **topic\_filter** T1.

**Important Note About Topic Filters**

Use the **topic\_filter** attribute with caution. In most cases, governance of QoS is improved by using discrete, named QoS profiles with no more than one of each kind of entity QoS section (**datareader\_qos**, **datawriter\_qos**, etc.) in each profile. If the **topic\_filter** attribute contains a typographical error or omission, it is possible for a topic not to match the intended filter expression. This can result in, for example, the entity being silently assigned the default QoS. The **topic\_filter** attribute may be preferred in cases where wildcards are used extensively to reduce duplication in the XML. In these cases, the resulting QoS of each entity should be independently and empirically confirmed. Tools that can help con-

firm an entity's QoS are *RTI Monitor* and (as described in [50.2.3.6 Viewing Resolved QoS Values on page 925](#)) the `rtixmloutpututility`.

## 50.2.5 QoS Profiles with a Single QoS

The definition of an individual QoS outside a profile is a shortcut for defining a QoS profile with a single QoS. For example:

```
<datawriter_qos name="KeepAllWriter">
  <history>
    <kind>KEEP_ALL_HISTORY_QOS</kind>
  </history>
</datawriter_qos>
```

is equivalent to:

```
<qos_profile name="KeepAllWriter">
  <datawriter_qos>
    <history>
      <kind>KEEP_ALL_HISTORY_QOS</kind>
    </history>
  </datawriter_qos>
</qos_profile>
```

## 50.3 Example XML File

The QoS configuration of a *Entity* can be loaded from an XML file or string.

The file contents must follow an important hierarchy: the file contains one or more libraries; each library contains one or more profiles; each profile contains QoS settings.

Let's look at a very basic configuration file, just to get an idea of its contents. You will learn the meaning of each line as you read the rest of this chapter:

```
<?xml version="1.0" encoding="ISO-8859-1"?>
<!-- A XML configuration file -->
<dds version = 5.0.0>
  <qos_library name="RTILibrary">
    <!-- A QoS Profile is a set of related QoS -->
    <qos_profile name="StrictReliableCommunicationProfile">
      <datawriter_qos>
        <history>
          <kind>KEEP_ALL_HISTORY_QOS</kind>
        </history>
        <reliability>
          <kind>RELIABLE_RELIABILITY_QOS</kind>
        </reliability>
      </datawriter_qos>
      <datareader_qos>
        <history>
          <kind>KEEP_ALL_HISTORY_QOS</kind>
        </history>
        <reliability>
```

```

        <kind>RELIABLE_RELIABILITY_QOS</kind>
    </reliability>
</datareader_qos>
</qos_profile>
<!--Individual QoS are shortcuts for QoS Profiles with 1 QoS-->
<datawriter_qos name="KeepAllWriter">
    <history>
        <kind>KEEP_ALL_HISTORY_QOS</kind>
    </history>
</datawriter_qos>
</qos_library>
</dds>

```

See `<NDDSHOME>/resource/xml/NDDS_QOS_PROFILES.example.xml` for another example; this file contains the default QoS values for all entity kinds.

## 50.4 Tags for Configuring QoS with XML

To configure the QoS for an *Entity* using XML, use the following tags:

- `<participant_factory_qos>`

**Note:** The only QoS policies that can be configured for the DomainParticipantFactory are `<entity_factory>` and `<logging>`.

- `<domain_participant_qos>`
- `<publisher_qos>`
- `<subscriber_qos>`
- `<topic_qos>`
- `<datawriter_qos>` or `<writer_qos>` (`writer_qos` is valid only with DTD validation)
- `<datareader_qos>` or `<reader_qos>` (`reader_qos` is valid only with DTD validation)

Each QoS can be identified by a name. The QoS can inherit its values from other QoSs described in the XML file. For example:

```

<datawriter_qos name="DerivedWriterQos" base_name="Lib::BaseWriterQos">
    <history>
        <kind>KEEP_ALL_HISTORY_QOS</kind>
    </history>
</datawriter_qos>

```

In the above example, the `datawriter_qos` named 'DerivedWriterQos' inherits the values from 'BaseWriterQos' in the library 'Lib'. The HistoryQosPolicy **kind** is set to `KEEP_ALL_HISTORY_QOS`.

Each XML tag with an associated name can be uniquely identified by its fully qualified name in C++ style.

The writer, reader and topic QoSs can also contain an attribute called **topic\_filter** that will be used to associate a set of topics to a specific QoS when that QoS is part of a QoS profile. See [50.2.4 Topic Filters on page 926](#) and [50.2 QoS Profiles on page 906](#).

## 50.4.1 QoS Policies

The fields in a QoS Policy are described in XML using a 1-to-1 mapping with the equivalent C representation. For example, the Reliability QoS Policy is represented with the following C structures:

```
struct DDS_Duration_t {
    DDS_Long sec;
    DDS_UnsignedLong nanosec;
}
struct DDS_ReliabilityQoSPolicy {
    DDS_ReliabilityQoSPolicyKind kind;
    DDS_Duration_t max_blocking_time;
}
```

The equivalent representation in XML is as follows:

```
<reliability>
  <kind></kind>
  <max_blocking_time>
    <sec></sec>
    <nanosec></nanosec>
  </max_blocking_time>
</reliability>
```

## 50.4.2 Sequences

In general, sequences in QoS Policies are described with the following XML format:

```
<a_sequence_member_name>
  <element>...</element>
  <element>...</element>
  ...
</a_sequence_member_name>
```

Each element of the sequence is enclosed in an `<element>` tag. For example:

```
<property>
  <value>
    <element>
      <name>my name</name>
      <value>my value</value>
    </element>
    <element>
      <name>my name2</name>
      <value>my value2</value>
    </element>
  </value>
</property>
```

A sequence without elements represents a sequence of length 0. For example:

```
<discovery>
  <!-- initial_peers sequence contains zero elements -->
  <initial_peers/>
</discovery>
```

For sequences that may have a default initialization that is *not empty* (such as the **initial\_peers** field in the [44.2 DISCOVERY QoS Policy \(DDS Extension\) on page 699](#)), using the above construct would result in an empty list and not the default value. So to simply show a sequence for the sake of completeness, but not change its default value, comment it out, as follows:

```
<discovery>
  <!-- initial_peers sequence contains the default value -->
  <!-- <initial_peers/> -->
</discovery>
```

As a general rule, sequences defined in a derived QoS will replace the corresponding sequences in the base QoS. (The concepts of *derived* and *base* QoS are described in [50.2.3 QoS Profile Inheritance and Composition on page 910](#).) For example, consider the following:

```
<qos_profile name="MyBaseProfile">
  <domain_participant_qos>
    <discovery>
      <initial_peers>
        <element>192.168.1.1</element>
        <element>192.168.1.2</element>
      </initial_peers>
    </discovery>
  </domain_participant_qos>
</qos_profile>
<qos_profile name="MyDerivedProfile" base_name="MyBaseProfile">
  <domain_participant_qos>
    <discovery>
      <initial_peers>
        <element>192.168.1.3</element>
      </initial_peers>
    </discovery>
  </domain_participant_qos>
</qos_profile>
```

The initial peers sequence defined above in the participant QoS of MyDerivedProfile will contain a single element with a value 192.168.1.3. The elements 192.168.1.1 and 192.168.1.2 will not be inherited. However, there is one exception to this behavior.

The `<property>` and `<data_tags>` tags provide an attribute called **inherit** that allows you to choose the inheritance behavior for the sequence defined within the tag.

By default, the value of the attribute **inherit** is true. Therefore, the `<property>` tag defined within a derived QoS profile will inherit its elements from the `<property>` tag defined within a base QoS profile.

In the following example, the property sequence defined in the participant QoS of MyDerivedProfile will contain two properties:

- **dds.transport.UDPv4.builtin.send\_socket\_buffer\_size** will be inherited from the base profile and have the value 524288.
- **dds.transport.UDPv4.builtin.recv\_socket\_buffer\_size** will overwrite the value defined in the base QoS profile with 1048576.

```
<qos_profile name="MyBaseProfile">
  <domain_participant_qos>
    <property>
      <value>
        <element>
          <name>
            dds.transport.UDPv4.builtin.send_socket_buffer_size
          </name>
          <value>524288</value>
        </element>
        <element>
          <name>
            dds.transport.UDPv4.builtin.recv_socket_buffer_size
          </name>
          <value>2097152</value>
        </element>
      </value>
    </property>
  </domain_participant_qos>
</qos_profile>
<qos_profile name="MyDerivedProfile" base_name="MyBaseProfile">
  <domain_participant_qos>
    <property>
      <value>
        <element>
          <name>
            dds.transport.UDPv4.builtin.recv_socket_buffer_size
          </name>
          <value>1048576</value>
        </element>
      </value>
    </property>
  </domain_participant_qos>
</qos_profile>
```

To discard all the properties defined in the base QoS profile, set **inherit** to false.

In the following example, the property sequence defined in the participant QoS of MyDerivedProfile will contain a single property named **dds.transport.UDPv4.builtin.recv\_socket\_buffer\_size**, with a value of 1048576. The property **dds.transport.UDPv4.builtin.send\_socket\_buffer\_size** will not be inherited.

```
<qos_profile name="MyBaseProfile">
  <participant_qos>
    <property>
      <value>
        <element>
          <name>
            dds.transport.UDPv4.builtin.send_socket_buffer_size
```

```

        </name>
        <value>524288</value>
    </element>
</element>
    <name>
        dds.transport.UDPv4.builtin.recv_socket_buffer_size
    </name>
    <value>2097152</value>
</element>
</value>
</property>
</domain_participant_qos>
</qos_profile>
<qos_profile name="MyDerivedProfile" base_name="MyBaseProfile"
    <participant_qos>
        <property inherit="false">
            <value>
                <element>
                    <name>
                        dds.transport.UDPv4.builtin.recv_socket_buffer_size
                    </name>
                    <value>1048576</value>
                </element>
            </value>
        </property>
    </domain_participant_qos>
</qos_profile>

```

### 50.4.3 Arrays

In general, the arrays contained in the QoS Policies are described with the following XML format:

```

<an_array_member_name>
    <element>...</element>
    <element>...</element>
    ...
</an_array_member_name>

```

Each element of the array is enclosed in an <element> tag.

As a special case, arrays of octets are represented with a single XML tag enclosing an array of decimal/hexadecimal values between 0..255 separated with commas.

For example:

```

<reader_qos>
    ...
    <protocol>
        <virtual_guid>
            <value>
                1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16
            </value>
        </virtual_guid>
    </protocol>
</reader_qos>

```

## 50.4.4 Enumeration Values

Enumeration values are usually represented using the programming language name without the `DDS_` or `NDDS_` prefix. For example:

```
<history>
  <kind>KEEP_ALL_HISTORY_QOS</kind>
</history>
```

You can get the actual enumeration values by using the XSD file distributed with *Connex*. See [50.9.2 XML File Validation During Editing on page 947](#). (Note: the XSD file provides stricter validation and better auto-completion than the corresponding DTD file.)

## 50.4.5 Time Values (Durations)

You can use the following special values for fields that require seconds or nanoseconds:

- `DURATION_INFINITE_SEC`
- `DURATION_ZERO_SEC`
- `DURATION_INFINITE_NSEC`
- `DURATION_ZERO_NSEC`
- `DURATION_AUTO_SEC`
- `DURATION_AUTO_NSEC`

For example:

```
<deadline>
  <period>
    <sec>DURATION_INFINITE_SEC</sec>
    <nanosec>DURATION_INFINITE_NSEC</nanosec>
  </period>
</deadline>
```

These values are the same as the programming language names without the `DDS_` or `NDDS_` prefix. You can find these special values by using the XSD file distributed with *Connex*. See [50.9.2 XML File Validation During Editing on page 947](#). (Note: the XSD file provides stricter validation and better auto-completion than the corresponding DTD file.)

## 50.4.6 Transport Properties

You can configure transport plugins using the *DomainParticipant's* [47.19 PROPERTY QoS Policy \(DDS Extension\) on page 837](#).

- Properties for the builtin transports are described in [51.6 Setting Builtin Transport Properties with the PropertyQoS Policy on page 960](#). You can also set these properties in XML using the

<transport\_builtin> tag.

- Properties for other transport plugins such as *RTI TCP Transport*<sup>1</sup> are described in their respective chapters in this manual.

This example configures the builtin UDPv4 transport using the <transport\_builtin> tags:

```
<domain_participant_qos>
  <transport_builtin>
    <udpv4>
      <message_size_max>1024</message_size_max>
    </udpv4>
  </transport_builtin>
</domain_participant_qos>
```

You can do the same thing with the UDPv6 (<udpv6>) and SHMEM (<shmem>) transports (and, if *RTI Real-Time WAN Transport* is installed, with UDPv4\_WAN (<udp4\_wan>)). For example:

```
<domain_participant_qos>
  <transport_builtin>
    <udpv6>
      <message_size_max>1024</message_size_max>
    </udpv6>
  </transport_builtin>
</domain_participant_qos>
```

You cannot use the <transport\_builtin> tag for the other transport plugins, like TCP, DTLS, WAN, LBRTPS, and ZRTPS. (You must use the [47.19 PROPERTY QosPolicy \(DDS Extension\) on page 837](#) properties for those.)

The following example configures the builtin UDPv4 transport using the legacy approach, via regular XML tags; you can find the names of these [47.19 PROPERTY QosPolicy \(DDS Extension\) on page 837](#) properties in the [Property Reference Guide](#):

```
<domain_participant_qos>
  <property>
    <value>
      <element>
        <name>dds.transport.UDPv4.builtin.parent.message_size_max</name>
        <value>65507</value>
      </element>
      <element>
        <name>dds.transport.UDPv4.builtin.send_socket_buffer_size</name>
        <value>131072</value>
      </element>
      <element>
        <name>dds.transport.UDPv4.builtin.recv_socket_buffer_size</name>
        <value>131072</value>
      </element>
    </value>
  </property>
</domain_participant_qos>
```

<sup>1</sup>*RTI TCP Transport* is included with *Connex*, but is not enabled by default.

```

</property>
</domain_participant_qos>

```

Some of the properties in the [Property Reference Guide](#) are described as "promoted" to `<transport_builtin>` tag usage. For example, `dds.transport.UDPv4.builtin.send_socket_buffer_size` can be entered either in a `<name>` element as shown above or via the `<transport_builtin>` tag as shown here:

```

<domain_participant_qos>
  <transport_builtin>
    <udpv4>
      <send_socket_buffer_size>131072</send_socket_buffer_size>
    </udpv4>
  </transport_builtin>
</domain_participant_qos>

```

All of the UDPv4, UDPv4\_WAN (if installed), UDPv6, and SHMEM transport properties (except those that are private or deprecated) have been "promoted" for use in a `<transport_builtin>` tag, if desired; however, the legacy way of using the [47.19 PROPERTY QoS Policy \(DDS Extension\) on page 837](#) properties (as described in the [Property Reference Guide](#)) is still supported. The `<transport_builtin>` tag is simply an easier way to configure your transports when using XML, for those properties that support it.

Note that programmatically, you must use the properties. For example:

```

retCode = DDS_PropertyQoSPolicyHelper_add_property(
    &participantQos.property,
    "dds.transport.UDPv4.builtin.parent.message_size_max",
    "5000",
    DDS_BOOLEAN_FALSE);

```

If you happen to set a transport property both ways—via the PROPERTY QoS `<name>` *and* via the `<transport_builtin>` tag—the `<transport_builtin>` method takes precedence. For example:

```

<qos_profile name="Precedence_Test_Tag_Properties">
  <participant_qos>
    <transport_builtin>
      <mask>SHMEM</mask>
      <shmem>
        <address_bit_count>0</address_bit_count>
      </shmem>
    </transport_builtin>
    <property>
      <value>
        <!-- SHMEM -->
        <element>
          <name>dds.transport.shmem.builtin.parent.address_bit_count</name>
          <value>1111</value>
          <propagate>true</propagate>
        </element>
      </value>
    </property>
  </participant_qos>
</qos_profile>

```

In this example, the `address_bit_count` will be 0.

Deprecated or private properties have no XML QoS representation via the `<transport_builtin>` tag. For example, `dds.transport.UDPv4.builtin.ignore_nonup_interfaces`, although it is a UDPv4 transport plugin property, cannot be specified via the `<transport_builtin>` tag, because it has been deprecated.

## 50.4.7 Thread Settings

See [Table 69.1 XML Tags for ThreadSettings\\_t](#).

## 50.4.8 Entity Names

The `name` and `role_name` fields in the [47.11 ENTITY\\_NAME QoS Policy \(DDS Extension\) on page 817](#) have three distinct possible values: NULL, an empty string, and a non-empty string. Each of these three states are specified in XML in a different way.

To specify that the `name` or `role_name` of an entity is NULL, use the `xsi:nil` attribute. The `xsi:nil` attribute can be set to either "true" or "false". For example, to set the participant name to NULL:

```
<participant_name>
  <name xsi:nil="true">
</participant_name>
```

To specify the empty string, leave the XML element empty:

```
<participant_name>
  <name/>
</participant_name>
```

To specify a non-empty string:

```
<participant_name>
  <name>"My Participant's Name"</name>
</participant_name>
```

## 50.5 How to Load XML-Specified QoS Settings

There are several ways to load XML QoS profiles into your application. In C, Traditional C++, Java and .NET, it's the singleton `DomainParticipantFactory` that loads these profiles. Applications using the Modern C++ API can create any number of instances of `dds::core::QosProvider` with different parameters to load different QoS profiles or, they can use the singleton `QosProvider::Default()`.

Here are the various approaches, listed in load order:

- `<NDDSHOME>/resource/xml/NDDS_QOS_PROFILES.xml`  
This file is loaded automatically *if it exists* (not the default) and `ignore_resource_profile` in the [43.2 PROFILE QoS Policy \(DDS Extension\) on page 691](#) is FALSE (the default). (*First to be loaded*)

**Note:** `NDDS_QOS_PROFILES.xml` does not exist by default. However, `NDDS_QOS_PROFILES.example.xml` is shipped with the host bundle of the product; you can copy it to `NDDS_QOS_PROFILES.xml` and modify it for your own use. The file contains the default QoS values that will be used for all entity kinds.

- **XML files in `NDDS_QOS_PROFILES`**

One or more XML files separated by semicolons referenced by the environment variable `NDDS_QOS_PROFILES` are loaded automatically if they exist *and* `ignore_environment_profile` in [43.2 PROFILE QosPolicy \(DDS Extension\) on page 691](#) is FALSE (the default).

Semicolons indicate to *Connex*t to load multiple files or strings all at once. For example:

On Linux and macOS systems, with bash:

```
export NDDS_QOS_PROFILES='file:///usr/local/default_dds_1.xml;
file:///usr/local/default_dds_2.xml'
```

From a Windows command prompt:

```
set NDDS_QOS_PROFILES=file://D:/Data/ConnexDDSEExample/default_dds_1.xml;
file://D:/Data/ConnexDDSEExample/default_dds_2.xml
```

- **<working directory>/`NDDS_QOS_PROFILES.xml`**

This file is loaded automatically if it exists *and* `ignore_user_profile` in [43.2 PROFILE QosPolicy \(DDS Extension\) on page 691](#) is FALSE (the default).

- **<working directory>/`USER_QOS_PROFILES.xml`**

This file is loaded automatically if it exists *and* `ignore_user_profile` in [43.2 PROFILE QosPolicy \(DDS Extension\) on page 691](#) is FALSE (the default).

- **XML files in `url_profile`**

One or more XML files referenced by `url_profile` (in [43.2 PROFILE QosPolicy \(DDS Extension\) on page 691](#)) will be loaded automatically if specified.

- **XML strings in `string_profile`**

The sequence of XML strings referenced by `string_profile` (in [43.2 PROFILE QosPolicy \(DDS Extension\) on page 691](#)) will be loaded automatically if specified. See [50.7 XML String Syntax on page 945](#). (*Last to be loaded*)

**Note:** The `url_profile` and `string_profile` fields are useful for adding profiles programmatically, when you do not want to use an environment variable.

You may use a combination of the above approaches.

The location of the XML documents (only files and strings are supported) is specified using URL (Uniform Resource Locator) format. See [50.8 URL Groups \(Loading Redundant Locations\) on page 945](#).

For example:

- File Specification: **file:///usr/local/default\_dds.xml**
- String Specification: **str://"<dds><qos\_library>...</qos\_library></dds>"**

If you omit the URL schema name, *Connex*t will assume a file name. For example:

- File Specification: **/usr/local/default\_dds.xml**

**Note:** The path you specify can be absolute or relative. If you specify a relative path, it should be a path to a file that is lower down in the file hierarchy, not higher up.

Duplicate QoS profiles are not allowed. *Connex*t will report an error message in these scenarios. To overwrite a QoS profile, use [50.2.3 QoS Profile Inheritance and Composition on page 910](#).

Several QoS profiles are built into the *Connex*t core libraries and can be used as starting points when configuring QoS for your *Connex*t applications. For details, see [50.4 Tags for Configuring QoS with XML on page 931](#).

To load redundant locations for a single XML file, see [50.8 URL Groups \(Loading Redundant Locations\) on page 945](#).

## 50.5.1 Loading, Reloading and Unloading Profiles

You do not have to explicitly call `load_profiles()`. QoS profiles are loaded when any of these `DomainParticipantFactory` operations are called:

- `create_participant()` (see [16.3.1 Creating a DomainParticipant on page 87](#))
- `create_participant_with_profile()` (see [16.3.1 Creating a DomainParticipant on page 87](#))
- `get_<entity>_qos_from_profile()` (where `<entity>` is **participant**, **topic**, **publisher**, **subscriber**, **datawriter**, or **datareader**) (see [16.2.5 Getting QoS Values from a QoS Profile on page 80](#))
- `get_<entity>_qos_from_profile_w_topic_name()` (where `<entity>` is **topic**, **datawriter**, or **datareader**) (see [16.2.5 Getting QoS Values from a QoS Profile on page 80](#))
- `get_default_participant_qos()` (see [16.2.2 Getting and Setting Default QoS for DomainParticipants on page 79](#))
- `get_qos_profile_libraries()` (See [50.10.1 Retrieving a List of Available Libraries on page 952](#))
- `get_qos_profiles()` (See [50.4 Tags for Configuring QoS with XML on page 931](#))
- `load_profiles()`
- `set_default_participant_qos_with_profile()` (see [16.2.2 Getting and Setting Default QoS for DomainParticipants on page 79](#))
- `set_default_library()` (see [30.4.4 Getting and Setting the Publisher's Default QoS Profile and Library on page 383](#))

- **set\_default\_profile()** (see [30.4.4 Getting and Setting the Publisher’s Default QoS Profile and Library on page 383](#))

In the Modern C++ API, the previous operations cause the default QosProvider (QosProvider::Default ()) to load the QoS profiles. Any other QosProvider that an application instantiates will load the QoS Profiles it is configured to load in its constructor.

QoS profiles are reloaded when either of these DomainParticipantFactory operations are called:

- **reload\_profiles()**
- **set\_qos()** (see [Chapter 49 Configuring Qos Programmatically on page 900](#))

It is important to distinguish between loading and reloading:

- *Loading* only happens when there are no previously loaded profiles. This could be when the profiles are loaded the first time or after a call to **unload\_profiles()**.
- *Reloading* replaces all previously loaded profiles. Reloading a profile does not change the QoS of entities that have already been created with previously loaded profiles.

The DomainParticipantFactory also has an **unload\_profiles()** operation that frees the resources associated with the XML QoS profiles.

```
DDS_ReturnCode_t unload_profiles()
```

## 50.6 XML File Syntax

The contents of the XML configuration file must follow an important hierarchy: the file contains one or more libraries; each library contains one or more profiles; each profile contains QoS settings.

In addition, the file must follow these syntax rules:

- The syntax is XML and the character encoding is UTF-8.
- Opening tags are enclosed in <>; closing tags are enclosed in </>.
- A tag value is a UTF-8 encoded string. Legal values are alphanumeric characters. The middleware’s parser will remove all leading and trailing spaces<sup>a</sup> from the string before it is processed.
- For example, <tag> value </tag> is the same as <tag>value</tag>.

<sup>a</sup>Leading and trailing spaces in enumeration fields will not be considered valid if you use the distributed XSD document to do validation at run-time with a code editor.

- All values are case-sensitive unless otherwise stated.
- Comments are enclosed as follows: `<!-- comment -->`.
- The root tag of the configuration file must be `<dds>` and end with `</dds>`.
- The primitive types for tag values are specified in [Table 50.1 Supported Tag Values](#).

**Table 50.1 Supported Tag Values**

Type	Format	Notes
DDS_Boolean	true, false	Not case-sensitive
DDS_Enum	A string. Legal values are those listed in the API Reference HTML documentation for the C or Java API.	Must be specified as a string. (Do not use numeric values.)
DDS_Long	-2147483648 to 2147483647 or 0x80000000 to 0x7fffffff or LENGTH_UNLIMITED or DDS_LENGTH_UNLIMITED	A 32-bit signed integer
DDS_UnsignedLong	0 to 4294967296 or 0 to 0xffffffff	A 32-bit unsigned integer
String	UTF-8 character string	All leading and trailing spaces are ignored between two tags

See also:

- [50.6.1 Using Environment Variables in XML below](#)
- [50.6.2 Using Special Characters in XML on the next page](#)
- [50.6.3 Specifying Fully Qualified Names in XML on the next page](#)

## 50.6.1 Using Environment Variables in XML

The text within an XML tag and attribute can refer to environment variable. To do so, use the following notation:

```
$(MY_VARIABLE)
```

For example:

```
<element attr="The attribute is $(MY_ATTRIBUTE)">
  <name>The name is $(MY_NAME)</name>
  <value>The value is $(MY_VALUE)</value>
</element>
```

When the *Connex* XML parser parses the above tags, it will replace the references to environment variables with their actual values.

## 50.6.2 Using Special Characters in XML

In the XML QoS configuration file, you may sometimes want to use special characters for the name of an element. If so, escape them by surrounding the attribute value with **&quot;** symbols in XML. The **&quot;** symbol is a special escape character within the XML standard that represents double quotes (").

For example:

```
<qos_profile name="&quot;&lt;MySpecial::NameProfile&gt;&quot;">
</qos_profile>
```

The name of this profile is **<MySpecial::NameProfile>**. It contains special characters like **<**, **>** and **:** within its name. When not escaped, **":"** is often used as a name separator when referring to an element in the XML hierarchy. (See [50.6.3 Specifying Fully Qualified Names in XML](#) below.)

You can use the same scheme when inheriting from the QoS profile in the **base\_name** attribute or the **<base\_name>** tag.

For example:

```
<qos_profile name="SpecialNameDerived"
  is_default_qos="true">
  <base_name>
    <element>Data_Library::&quot;&lt;MySpecial::NameProfile&gt;&quot;</element>
  </base_name>
</qos_profile>

<qos_profile name="SpecialNameDerived"
  base_name="Data_Library::&quot;&lt;MySpecial::NameProfile&gt;&quot;"
  is_default_qos="true">
</qos_profile>
```

In this example, the profile is contained within the **Data\_Library** QoS Library.

This idea is applicable to all tags that can perform inheritance (any tag that has a **base\_name** attribute or can contain the **<base\_name>** tag).

## 50.6.3 Specifying Fully Qualified Names in XML

When specifying a parent to inherit from in the **base\_name** attribute or the **<base\_name>** tag of a QoS policy in an XML file, you can refer to elements using a fully qualified naming scheme. This causes the search to begin from the root of the XML Document Object Model (DOM) tree parsed by the XML parser.

For that you need to follow this scheme:

```
<parent_tag_name>::<child_tag_name>::<grandchild_tag_name> . . .
```

The resulting name should match the declaration hierarchy. The declaration hierarchy represents the ordering of the tags as described in the XML schema. For QoS configuration, the hierarchy is as

follows:

```
<qos_library_name>::

```

Here "::" is the path separator in the XML DOM tree. Specifying a fully qualified name is useful when you want to refer to elements within another `<qos_library>` tag.

For example:

```
<qos_library name="Data_Library">
  <qos_profile name="Data_Profile" base_name="BuiltinQosLib::Generic.StrictReliable">
    .
    .
    .
  </qos_profile>
</qos_library>
```

## 50.7 XML String Syntax

XML profiles can be described using strings. This configuration is useful for architectures without a file system.

There are two different ways to configure *Entities* via XML strings:

- String URLs are prefixed by the URI schema **str://** and enclosed in double quotes. For example:

```
str://"<dds><qos_library>...</qos_library></dds>"
```

The string URLs can be specified in the environment variable **NDDS\_QOS\_PROFILES** as well as in the field **url\_profile** in [43.2 PROFILE QoS Policy \(DDS Extension\) on page 691](#). Each string URL must contain a whole XML document.

- The **string\_profile** field in the [43.2 PROFILE QoS Policy \(DDS Extension\) on page 691](#) allows you to split an XML document into multiple strings. For example:

```
const char * MyXML[4] =
{
    "<dds>",
    "<qos_library name=\"MyLibrary\">",
    "</qos_library>",
    "</dds>"
};
factoryQos.profile.string_profile.from_array(MyXML, 4);
```

Only one XML document can be specified with the **string\_profile** field.

## 50.8 URL Groups (Loading Redundant Locations)

Use URL groups to specify multiple locations for a single XML file, to provide redundancy and fault tolerance. Specify the locations by enclosing them in square brackets. The syntax of a URL group is:

```
[URL1 | URL2 | URL2 | ... | URLn]
```

You can specify either an XML file or an XML string. For example:

```
[file:///usr/local/default_dds.xml | file:///usr/local/alternative_default_dds.xml |
str://"<dds><qos_library name="Data_Library"><qos_profile name="Data_Profile" base_
name="BuiltinQosLibExp::Generic.StrictReliable" is_default_qos="true" /></qos_
library></dds>"]
```

The OR operand (`()`) tells *Connex*t to load one file/string at a time, starting from the left. If the first file/string is not available, *Connex*t tries loading the next one, and so on. For example, if the first location loaded successfully, *Connex*t does not load the subsequent locations. Brackets are not required for URL groups with a single file/string. In fact, single XML files separated by semicolons are URL groups without brackets.

Here's an example (on a Linux system with bash) that loads multiple files, including one bracketed URL group with redundant file locations:

```
export NDDS_QOS_PROFILES='[file:///usr/local/default_dds.xml |
file:///usr/local/alternative_default_dds.xml]; file:///usr/local/default_dds_2.xml'
```

See also [50.5 How to Load XML-Specified QoS Settings on page 939](#) for information on loading multiple XML files.

## 50.9 How the XML is Validated

### 50.9.1 Validation at Run-Time

*Connex*t validates the input XML files using a builtin Document Type Definition (DTD).

You can find a copy of the builtin DTD in `<NDDSHOME>/resource/schema/rti_dds_qos_profiles.dtd`. (This is only a *copy* of what the *Connex*t core uses. Changing this file has no effect unless you specify its path with the `<!DOCTYPE>` tag, described below.)

You can overwrite the builtin DTD by using the XML tag, `<!DOCTYPE>`. For example, the following indicates that *Connex*t must use a DTD file from a user's directory to perform validation:

```
<!DOCTYPE dds SYSTEM "/local/joe/rti/dds/mydds.dtd">
```

- The DTD path can be absolute, or relative to the application's current working directory.
- If the specified file does not exist, you will see the following error:

```
RTIXMLDtdParser_parse:!open DTD file
```

- If you do not specify the `DOCTYPE` tag in the XML file, the builtin DTD is used.
- The XML files used by *Connex*t can be versioned using the attribute `version` in the `<dds>` tag. For example:

```
<dds version="7.0.0">
  ...
</dds>
```

Although the attribute `version` is not required during the validation process, it helps to detect DTD incompatibility scenarios by providing better error messages.

For example, if an application using *Connex* 7.0.0 tries to load an XML file from *Connex* 4.5z and there is some incompatibility in the XML content, the following parsing error will be printed:

```
ATTENTION: The version declared in this file (4.5z) is different from the version of
Connex (7.0.0).
If these versions are not compatible, that incompatibility could be the cause of this
error.
```

## 50.9.2 XML File Validation During Editing

*Connex* provides DTD and XSD files that describe the format of the XML content. We recommend including a reference to one of these documents in the XML file that contains the QoS profiles—this provides helpful features in code editors such as Visual Studio and Eclipse, including validation and auto-completion while you are editing the XML file.

The DTD and XSD definitions of the XML elements are in `<NDDSHOME>/resource/schema/rti_dds_qos_profiles.dtd` and `<NDDSHOME>/resource/schema/rti_dds_qos_profiles.xsd`, respectively. (`<NDDSHOME>` is described in [Paths Mentioned in Documentation on page 1.](#))

To include a reference to the XSD document in your XML file, use the attribute `xsi:noNamespaceSchemaLocation` in the `<dds>` tag. For example:

```
<?xml version="1.0" encoding="UTF-8"?>
<dds xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:noNamespaceSchemaLocation=
"<NDDSHOME>/resource/schema/rti_dds_qos_profiles.xsd">
  ...
</dds>
```

To include a reference to the DTD document in your XML file use the `<!DOCTYPE>` tag. For example:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE dds SYSTEM
"<NDDSHOME>/resource/schema/rti_dds_qos_profiles.dtd">
<dds>
  ...
</dds>
```

We recommend including a reference to the XSD file in the XML documents because it provides stricter validation and better auto-completion than the corresponding DTD file.

## 50.9.3 Skipping Element Validation: the `must_interpret` Attribute

The `must_interpret` attribute controls how the parser behaves when it fails to validate an XML element. It allows you to ignore the incompatibility of XML files between *Connex* versions, or between vendors.

XML elements that have the `must_interpret` attribute set to “false” will not trigger a validation failure by the XML parser. If the attribute is not specified, the default value is “true”, in which case the validation described in [50.9.1 Validation at Run-Time on page 946](#) and [50.9.2 XML File Validation During Editing on the previous page](#) will be performed.

**Note:** Adding the `must_interpret` attribute to your XML file breaks compatibility with versions of *Connex* prior to 7.0.0. For example:

```
<reliability must_interpret="true">
  <kind>RELIABLE_RELIABILITY_QOS</kind>
</reliability>
```

This is because, in releases prior to 7.0.0, `<reliability>` is not supposed to have the `must_interpret` attribute at all.

### 50.9.3.1 Validation of an XML element

The XML parser checks three aspects while validating an element:

- **The element tag.** Is this a valid (known) tag?
- **The element attributes.** Are the attributes valid for the current tag? Are there required attributes not specified for the current tag?
- **The element’s parent.** Is this one of the possible valid elements that the parent can have as children?

If an element is valid with respect to these three aspects, the parser continues validating its children.

If an element is invalid, the parser will fail if the element's `must_interpret` attribute is set to true—either because `must_interpret` is not specified or because it is explicitly set to true.

When `must_interpret` is false, the parser allows invalid tags and attributes, as follows:

- If the element’s tag or parent is invalid, the parser doesn't even look at its children. Validation continues in the next element of the XML tree.
- If the element’s tag and parent are valid, the parser does look at its children. Those children for which `must_interpret` is not false may fail validation.
- The parser always allows unexpected or missing attributes as long as the tag's `must_interpret` attribute is false.

### 50.9.3.2 Examples

The following examples help clarify how the `must_interpret` attribute works. In these examples, `<custom_tag>`, `<custom_child>`, and `custom_attribute` represent tags or attributes that are invalid for the current XML parser. These could be elements supported only in modern versions of *Connex*. Or they could be custom elements that are understood only by a specific vendor implementation.

#### 50.9.3.2.1 First example: invalid tag with `must_interpret="false"`

The XML parser validation succeeds if there is an invalid tag, because this tag has the `must_interpret` attribute explicitly set to false. The parser in this scenario ignores the XML tag because it doesn't understand it. The parser also ignores the children. Neither is validated.

```
<datareader_qos>
  <custom_tag must_interpret="false">
    <custom_child>Custom value</custom_child>
  </custom_tag>
</datareader_qos>
```

#### 50.9.3.2.2 Second example: valid tag with invalid attributes and `must_interpret="false"`

The XML parser validation succeeds if a tag has invalid attributes, as long as it also has the `must_interpret` attribute explicitly set to false. The XML parser skips validation of a tag's attributes whenever `must_interpret` is false. It doesn't enforce required attributes either. The parser continues validating the tag's children. Validation succeeds in this case because the children are valid.

```
<datareader_qos>
  <durability must_interpret="false" custom_attribute="foo">
    <kind>VOLATILE_DURABILITY_QOS</kind>
    <direct_communication>true</direct_communication>
  </durability>
</datareader_qos>
```

#### 50.9.3.2.3 Third example: valid tag with invalid attributes, invalid children, and `must_interpret="false"`

The parent tag succeeds, even with an invalid attribute, because `must_interpret` is set to false. Each of the invalid children requires `must_interpret="false"` if we want to prevent a validation failure of the XML parser. Validation does not succeed in this case because the invalid tag `<custom_child>` does not have `must_interpret="false"`.

```
<datareader_qos>
  <durability must_interpret="false" custom_attribute="foo">
    <custom_child>Custom value</custom_child>
  </durability>
</datareader_qos>
```

## 50.10 Using QoS Profiles in Your *Connex* Application

You can use the operations listed in [Table 50.2 Operations for Working with QoS Profiles](#) to refer to and use QoS profiles (see [50.2 QoS Profiles on page 906](#)) described in XML files and XML strings.

**Table 50.2 Operations for Working with QoS Profiles**

Working With ...	Profile-Related Operations	Reference
DataReaders	set_qos_with_profile	<a href="#">40.9.3 Changing QoS Settings After the DataReader has been Created on page 657</a>
DataWriters	set_qos_with_profile	<a href="#">31.15.3 Changing QoS Settings After the DataWriter Has Been Created on page 439</a>

	<code>set_qos_with_profile</code>	<a href="#">39.4.3 Changing QoS Settings After Subscriber Has Been Created on page 606</a>
Topics	<code>set_qos_with_profile</code>	<a href="#">18.1.3 Setting Topic QoS Policies on page 250</a>

Note: For the Modern C++ API, please refer to the RTI Connext API Reference HTML documentation, [Configuring QoS Profiles with XML](#).

## 50.10.1 Retrieving a List of Available Libraries

To get a list of available QoS libraries, call the `DomainParticipantFactory`'s `get_qos_profile_libraries()` operation, which returns the names of all QoS libraries that have been loaded by *Connext*.

```
DDS_ReturnCode_t get_qos_profile_libraries (struct DDS_StringSeq *profile_names)
```

## 50.10.2 Retrieving a List of Available QoS Profiles

To get a list of available QoS profiles, call the `DomainParticipantFactory`'s `get_qos_profiles()` operation, which returns the names of all profiles within a specified QoS library. Either the input QoS

library name must be specified or the default profile library must have been set prior to calling this function.

```
DDS_ReturnCode_t get_qos_profiles (struct DDS_StringSeq *profile_names,  
                                  const char *library_name)
```

## 50.11 Configuring Logging Via XML

Logging can be configured via XML using the DomainParticipantFactory's LoggingQosPolicy. See [54.3 Configuring Logging via XML on page 1099](#) for additional details.

# Part 8: Working with Transports in Connex

This section includes:

- [UDPv4, UDPv6, and Shared Memory Transport Plugins \(Chapter 51 on page 955\)](#)
- [RTI Real-Time WAN Transport \(Chapter 52 on page 986\)](#)
- [RTI TCP Transport \(Chapter 53 on page 1051\)](#)

# Chapter 51 UDPv4, UDPv6, and Shared Memory Transport Plugins

*Connex*t has a pluggable-transport architecture. The core of *Connex*t is transport agnostic—it does not make any assumptions about the actual transports used to send and receive messages. Instead, *Connex*t uses an abstract "transport API" to interact with the transport plugins that implement that API. A transport plugin implements the abstract transport API, and performs the actual work of sending and receiving messages over a physical transport.

There are essentially three categories of transport plugins:

- **Builtin Transport Plugins** *Connex*t comes with a set of commonly used transport plugins. These 'builtin' plugins include UDPv4, UDPv6, and shared memory. So that *Connex*t applications can work out-of-the-box, some of these are enabled by default (see [44.7 TRANSPORT\\_BUILTIN QosPolicy \(DDS Extension\) on page 725](#)).
- **Extension Transport Plugins** RTI offers extension transports, including *RTI Real-Time WAN Transport* (see [Chapter 52 RTI Real-Time WAN Transport on page 986](#)) and *RTI TCP Transport* (see [Chapter 53 RTI TCP Transport on page 1051](#)).
- **Custom-Developed Transport Plugins** RTI supports the use of custom transport plugins. This is a powerful capability that distinguishes *Connex*t from competing middleware approaches. If you are interested in developing a custom transport plugin for *Connex*t, please contact your local RTI representative or email [sales@rti.com](mailto:sales@rti.com).

## 51.1 Builtin Transport Plugins

There are two ways in which the builtin transport plugins may be registered:

- **Default builtin Transport Instances:** Builtin transports that are turned "on" in the [44.7 TRANSPORT\\_BUILTIN QosPolicy \(DDS Extension\) on page 725](#) are implicitly registered when (a) the *DomainParticipant* is enabled, (b) the first

*DataWriter/DataReader* is created, or (c) you look up a builtin *DataReader* (by calling **lookup\_datareader()** on a Subscriber), whichever happens first. The builtin transport plugins have default properties. If you want to change these properties, do so *before*<sup>1</sup> the transports are registered.

- **Other Transport Instances:** There are two ways to install non-default builtin transport instances:
  - Transport plugins may be explicitly registered by first creating an instance of the transport plugin (by calling **NDDS\_Transport\_UDPv4\_new()**, **NDDS\_Transport\_UDPv6\_new()** or **NDDS\_Transport\_Shmem\_new()**, see [51.4 Explicitly Creating Builtin Transport Plugin Instances on page 958](#)), then calling **register\_transport()** ([51.7 Installing Additional Builtin Transport Plugins with register\\_transport\(\) on page 979](#)). (For example, suppose you want an extra instance of a transport.) (Not available for the Java or C# API.)
  - Additional builtin transport instances can also be installed through the [47.19 PROPERTY QosPolicy \(DDS Extension\) on page 837](#).

To configure the properties of the builtin transports:

- Set properties by calling **set\_builtin\_transport\_property()** (see [51.5 Setting Builtin Transport Properties of Default Transport Instance—get/set\\_builtin\\_transport\\_properties\(\) on page 959](#))

or

- Specify predefined property strings in the *DomainParticipant's* **PropertyQosPolicy**, as described in [51.6 Setting Builtin Transport Properties with the PropertyQosPolicy on page 960](#).

For other builtin transport instances:

- If the builtin transport plugin is created with **NDDS\_Transport\_UDPv4\_new()**, **NDDS\_Transport\_UDPv6\_new()** or **NDDS\_Transport\_Shmem\_new()**, properties can be specified during creation time. See [51.4 Explicitly Creating Builtin Transport Plugin Instances on page 958](#).
- If the additional builtin transport instances are installed through the [47.19 PROPERTY QosPolicy \(DDS Extension\) on page 837](#), the properties of the builtin transport plugins can also be specified through that same **QosPolicy**.

## 51.2 Extension Transport Plugins

If you want to change the properties for an extension transport plugin, do so *before* the plugin is registered. Any transport property changes made after the plugin is registered will have no effect.

---

<sup>1</sup>Any transport property changes made after the plugin is registered will have no effect.

There are two ways to install an extension transport plugin:

- **Implicit Registration:** Transports can be installed through the predefined strings in the *DomainParticipant*'s *PropertyQoSPolicy*. Once the transport's properties are specified in the *PropertyQoSPolicy*, the transport will be implicitly registered when (a) the *DomainParticipant* is enabled, (b) the first *DataWriter/DataReader* is created, or (c) you look up a builtin *DataReader* (by calling `lookup_datareader()` on a Subscriber), whichever happens first.

QoS Policies can also be configured from XML resources (files, strings)—with this approach, you can change the QoS without recompiling the application. The QoS settings are automatically loaded by the *DomainParticipantFactory* when the first *DomainParticipant* is created. For more information, see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

- **Explicit Registration:** Transports may be explicitly registered by first creating an instance of the transport plugin (see [51.4 Explicitly Creating Builtin Transport Plugin Instances on the next page](#)) and then calling `register_transport()` (see [51.7 Installing Additional Builtin Transport Plugins with register\\_transport\(\) on page 979](#)).

## 51.3 The NDDSTransportSupport Class

The `register_transport()` and `set_builtin_transport_property()` operations are part of the *NDDSTransportSupport* class, which includes the operations listed in [Table 51.1 Transport Support Operations](#).

Table 51.1 Transport Support Operations

Operation	Description	Reference
get_transport_plugin	Retrieves a previously registered transport plugin.	<a href="#">51.7 Installing Additional Builtin Transport Plugins with register_transport() on page 979</a>
register_transport	Registers a transport plugin for use with a <i>DomainParticipant</i> .	
get_builtin_transport_property	Gets the properties used to create a builtin transport plugin.	<a href="#">51.5 Setting Builtin Transport Properties of Default Transport Instance—get/set_builtin_transport_properties() on the next page</a>
set_builtin_transport_property	Sets the properties used to create a builtin transport plugin.	
add_send_route	Adds a route for outgoing messages.	<a href="#">51.9.1 Adding a Send Route on page 983</a>
add_receive_route	Adds a route for incoming messages.	<a href="#">51.9.2 Adding a Receive Route on page 984</a>
lookup_transport	Looks up a transport plugin within a <i>DomainParticipant</i> .	<a href="#">51.9.3 Looking Up a Transport Plugin on page 985</a>

## 51.4 Explicitly Creating Builtin Transport Plugin Instances

The builtin transports (UDPv4, UDPv6, and Shared Memory) are implicitly created by default (if they are enabled via the [44.7 TRANSPORT\\_BUILTIN QoSPolicy \(DDS Extension\) on page 725](#)). Therefore, you only need to explicitly create a new instance if you want an extra instance (suppose you want two UDPv4 transports, one with special settings).

Transport plugins may be explicitly registered by first creating an instance of the transport plugin and then calling **register\_transport()** ([51.7 Installing Additional Builtin Transport Plugins with register\\_transport\(\) on page 979](#)). (For example, suppose you want an extra instance of a transport.) (Not available for the Java API.)

To create an instance of a builtin transport plugin, use one of the following functions:

```
NDDS_Transport_Plugin* NDDS_Transport_UDPv4_new (
    const struct NDDS_Transport_UDPv4_Property_t * property_in)
NDDS_Transport_Plugin* NDDS_Transport_UDPv6_new (
    const struct NDDS_Transport_UDPv6_Property_t * property_in)
NDDS_Transport_Plugin* NDDS_Transport_Shmem_new (
    const struct NDDS_Transport_Shmem_Property_t * property_in)
```

Where:

**property\_in**            Desired behavior of this transport. May be NULL for default properties.

For details on using these functions, please see the API Reference HTML documentation.

Your application may create and register multiple instances of these transport plugins with *Connex*. This may be done to partition the network interfaces across multiple DDS domains. However, note that the underlying transport, the operating system's IP layer, is still a "singleton." For example, if a unicast

transport has already bound to a port, and another unicast transport tries to bind to the same port, the second attempt will fail.

## 51.5 Setting Builtin Transport Properties of Default Transport Instance—`get/set_builtin_transport_properties()`

Perhaps you want to use one of the builtin transports, but need to modify the properties. (For default values, please see the API Reference HTML documentation.) Used together, the two operations below allow you to customize properties of the builtin transport when it is implicitly registered (see [51.1 Builtin Transport Plugins on page 955](#)).

**Note:** Another way to change the properties is with the Property QoSPolicy, see [51.6 Setting Builtin Transport Properties with the PropertyQoSPolicy on the next page](#). Changing properties with the Property QoSPolicy will overwrite the properties set by calling `set_builtin_transport_property()`.

```
DDS_ReturnCode_t
NDDSTransportSupport::get_builtin_transport_property (
    DDSDomainParticipant * participant_in,
    DDS_TransportBuiltinKind builtin_transport_kind_in,
    struct NDDS_Transport_Property_t
        &builtin_transport_property_inout)
DDS_ReturnCode_t
NDDSTransportSupport::set_builtin_transport_property (
    DDSDomainParticipant * participant_in,
    DDS_TransportBuiltinKind builtin_transport_kind_in,
    const struct NDDS_Transport_Property_t
        &builtin_transport_property_in)
```

Where:

<b>participant_in</b>	A valid non-NULL <i>DomainParticipant</i> that has not been enabled. If the <i>DomainParticipant</i> is already enabled when this operation is called, your transport property changes will not be reflected in the transport used by the <i>DomainParticipant's DataWriters</i> and <i>DataReaders</i> .
<b>builtin_transport_kind_in</b>	The builtin transport kind for which to specify the properties.
<b>builtin_transport_property_inout</b>	(Used by the “get” operation only.) The storage area where the retrieved property will be output. The specific type required by the <b>builtin_transport_kind_in</b> must be used.
<b>builtin_transport_property_in</b>	(Used by the “set” operation only.) The new transport property that will be used to create the builtin transport plugin. The specific type required by the <b>builtin_transport_kind_in</b> must be used.

In this example, we want to use the builtin UDPv4 transport, but with modified properties.

```
/* Before this point, create a disabled DomainParticipant */
struct NDDS_Transport_UDPv4_Property_t property =
    NDDS_TRANSPORT_UDPv4_PROPERTY_DEFAULT;
if (NDDSTransportSupport::get_builtin_transport_property (
    participant, DDS_TRANSPORTBUILTIN_UDPv4,
    (struct NDDS_Transport_Property_t&)property) !=
    DDS_RETCODE_OK) {
    printf("***Error: get builtin transport property\n");
```

```

}
/* Make your desired changes here */
/* For example, to increase the UDPv4 max msg size to 64K: */
property.parent.message_size_max = 65535;
property.recv_socket_buffer_size = 65535;
property.send_socket_buffer_size = 65535;
if (NDDSTransportSupport::set_builtin_transport_property(
    participant, DDS_TRANSPORTBUILTIN_UDPv4,
    (struct NDDS_Transport_Property_t&)property)
    != DDS_RETCODE_OK) {
    printf("***Error: set builtin transport property\n");
}
/* Enable the participant to turn on communications with
other participants in the DDS domain using the new
properties for the automatically registered builtin
transport plugins */
if (entity->enable() != DDS_RETCODE_OK) {
    printf("***Error: failed to enable entity\n");
}

```

**Note:** Builtin transport property changes will have no effect after the builtin transport has been registered. The builtin transports are implicitly registered when (a) the *DomainParticipant* is enabled, (b) the first *DataWriter/DataReader* is created, or (c) you lookup a builtin *DataReader*, whichever happens first.

## 51.6 Setting Builtin Transport Properties with the PropertyQosPolicy

The [47.19 PROPERTY QosPolicy \(DDS Extension\)](#) on page 837 allows you to set name/value pairs of data and attach them to an entity, such as a *DomainParticipant*.

To assign properties, use the `add_property()` operation:

```

DDS_ReturnCode_t DDSPropertyQosPolicyHelper::add_property
(DDS_PropertyQosPolicy policy,
 const char * name,
 const char * value,
 DDS_Boolean propagate)

```

For more information on `add_property()` and the other operations in the `DDSPropertyQosPolicyHelper` class, please see [Table 47.34 PropertyQoSPolicyHelper Operations](#), as well as the API Reference HTML documentation.

The ‘name’ part of the name/value pairs is a predefined string. The property names for the builtin transports are described in these tables:

- [Table 51.2 Properties for the Builtin UDPv4 Transport](#)
- [Table 51.3 Properties for Builtin UDPv6 Transport](#)
- [Table 51.4 Properties for Builtin Shared-Memory Transport](#)

See also:

- [51.6.1 Setting the Maximum Gather-Send Buffer Count for UDP Transports on page 977](#)
- [51.6.2 Formatting Rules for IPv6 ‘Allow’ and ‘Deny’ Address Lists on page 978](#)

**Note:**

Changing properties with the [47.19 PROPERTY QosPolicy \(DDS Extension\) on page 837](#) will overwrite any properties set by calling `set_builtin_transport_property()`.

**Table 51.2 Properties for the Builtin UDPv4 Transport**

Property Name (prefix with 'dds.transport.UDPv4.builtin.')	Property Value Description
parent.properties_bitmap	<p>A bitmap that defines various properties of the transport to the <i>Connex</i>t core.</p> <p>Currently, the only property supported is whether or not the transport plugin will always loan a buffer when <i>Connex</i>t tries to receive a message using the plugin. This is in support of a zero-copy interface.</p> <p>Default: 0</p>
parent.gather_send_buffer_count_max	<p>Specifies the maximum number of buffers that <i>Connex</i>t can pass to the <code>send()</code> method of a transport plugin.</p> <p>The transport plugin <code>send()</code> API supports a gather-send concept, where the <code>send()</code> call can take several discontinuous buffers, assemble and send them in a single message. This enables <i>Connex</i>t to send a message from parts obtained from different sources without first having to copy the parts into a single contiguous buffer.</p> <p>However, most transports that support a gather-send concept have an upper limit on the number of buffers that can be gathered and sent. Setting this value will prevent <i>Connex</i>t from trying to gather too many buffers into a send call for the transport plugin.</p> <p><i>Connex</i>t requires all transport-plugin implementations to support a gather-send of least a minimum number of buffers. This minimum number is <code>NDDS_TRANSPORT_PROPERTY_GATHER_SEND_BUFFER_COUNT_MIN</code>.</p> <p>See <a href="#">51.6.1 Setting the Maximum Gather-Send Buffer Count for UDP Transports on page 977</a>.</p> <p>Default: 16</p>
parent.message_size_max	<p>The maximum size of a message in bytes that can be sent or received by the transport plugin. Above this size, DDS-level fragmentation will occur. See <a href="#">34.3 Large Data Fragmentation on page 524</a>.</p> <p>This value must be set before the transport plugin is registered, so that <i>Connex</i>t can properly use the plugin.</p> <p>Default for Integrity platforms: 9216</p> <p>Default for non-Integrity platforms: 65507</p>

Table 51.2 Properties for the Builtin UDPv4 Transport

Property Name (prefix with 'dds.transport.UDPv4.builtin.')	Property Value Description
parent.allow_interfaces_list	<p>A list of strings, each identifying a range of interface addresses or an interface name. Interfaces must be specified as comma-separated strings, with each comma delimiting an interface. For example, the following are acceptable strings:</p> <pre>192.168.1.1 192.168.1.* 192.168.* 192.* ether0</pre> <p>If the list is non-empty, this "white" list is applied before the <a href="#">parent.deny_interfaces_list</a> below list. The <i>DomainParticipant</i> will use the resulting list of interfaces to inform its remote participant(s) about which unicast addresses may be used to send data to that <i>DomainParticipant</i>. The resulting list also controls the interfaces over which the <i>DomainParticipant</i> will send multicast traffic to the remote <i>DomainParticipants</i> (if multicast is supported on the platform).</p> <p><b>Note:</b> This property does not affect the interfaces that the transport uses to send unicast data <i>from</i> that <i>DomainParticipant</i>. That decision is made by the OS based on the destination address.</p> <p>You must manage the memory of the list. The memory may be freed after the <i>DomainParticipant</i> is deleted.</p> <p>The left-to-right order of this list matters if you are using the <a href="#">max_interface_count</a> to limit the allowable interfaces further. See <a href="#">max_interface_count</a>.</p> <p>Default: empty list that represents all available interfaces</p>
parent.deny_interfaces_list	<p>A list of strings, each identifying a range of interface addresses or an interface name. If the list is non-empty, deny the use of these interfaces. Interfaces must be specified as comma-separated strings, with each comma delimiting an interface. For example, the following are acceptable strings:</p> <pre>192.168.1.1 192.168.1.* 192.168.* 192.* ether0</pre> <p>This "black" list is applied after the <a href="#">parent.allow_interfaces_list</a> above list and filters out the interfaces that should <i>not</i> be used for receiving data. The resulting list also controls the interfaces over which the <i>DomainParticipant</i> will send multicast traffic to the remote <i>DomainParticipants</i> (if multicast is supported on the platform).</p> <p><b>Note:</b> This property does not affect the interfaces that the transport uses to send unicast data <i>from</i> a <i>DomainParticipant</i>. That decision is made by the OS based on the destination address.</p> <p>You must manage the memory of the list. The memory may be freed after the <i>DomainParticipant</i> is deleted.</p> <p>Default: empty list that represents no denied interfaces</p>

Table 51.2 Properties for the Builtin UDPv4 Transport

Property Name (prefix with 'dds.transport.UDPv4.builtin.')	Property Value Description
parent.max_interface_count	<p>How many of the addresses in your allowed interfaces list are used, at most, at any time.</p> <p>This feature is useful if you want to control the network interfaces on which your <i>DomainParticipants</i> receive data. For example, if you have one wired and one wireless interface in your allowed interfaces list <i>both</i> up and running, and <b>max_interface_count</b> is set to 1, the <i>DomainParticipant</i> will receive data over the interface you list first in the <b>allow_interfaces_list</b>—for example, the wired one. If the wired interface is not in use (for example, the device is undocked), then the <i>DomainParticipant</i> will receive data only over the next available up-and-running interface in your <b>allow_interfaces_list</b>, which would be the wireless one.</p> <p><b>Connex</b>t selects the preferred interface(s) by iterating over the list of allowed interfaces until the first <b>max_interfaces_count</b> of active interfaces encountered are announced. The order of iteration is left to right as specified in the <b>allow_interfaces_list</b> setting.</p> <p>This setting applies only if the <b>allow_interfaces_list</b> is not empty.</p> <p>The <b>max_interface_count</b> setting does not consider end-to-end connectivity to select interfaces. The decision is based purely on whether interfaces are up or down in a node. Therefore, this feature is not intended to be used in the following scenarios:</p> <ul style="list-style-type: none"> <li>• A <i>DomainParticipant</i> is not reachable by other <i>DomainParticipants</i> in all the interfaces in the <b>allow_interfaces_list</b>. This could occur if the <i>DomainParticipant</i> is in different subnets, and some of these subnets cannot be reached by other <i>DomainParticipants</i>.</li> <li>• End-to-end connectivity issues lead to situations in which the interfaces selected after applying <b>max_interface_count</b> cannot be reached by other <i>DomainParticipants</i>.</li> </ul> <p>This feature also affects multicast traffic by limiting the interfaces over which a <i>DomainParticipant</i> sends multicast traffic. The <b>(allow/deny)_multicast_interfaces_list</b> applies to the interfaces selected by using the <b>max_interfaces_count</b> property.</p> <p><b>Note:</b> If a pattern string in the <b>allow_interfaces_list</b> matches multiple interface addresses, and <b>max_interface_count</b> is set to a finite value, the order for the matching allowed interfaces is decided based on the order in which the operating system provides these interfaces.</p> <p>Default: LENGTH_UNLIMITED Range: [1, LENGTH_UNLIMITED]</p>
parent. allow_multicast_interfaces_list	<p>A list of strings, each identifying a range of interface addresses or an interface name. If the list is non-empty, allow the use of multicast only on these interfaces. If the list is empty, allow the use of all the allowed interfaces.</p> <p>Interfaces must be specified as comma-separated strings, with each comma delimiting an interface.</p> <p>This list sub-selects from the allowed interfaces that are obtained after applying the <a href="#">parent.allow_interfaces_list on the previous page</a> "white" list and the <a href="#">parent.deny_interfaces_list on the previous page</a> "black" list. From that resulting list, <a href="#">parent.deny_multicast_interfaces_list below</a> is applied. Multicast output will be sent and may be received over the interfaces in the resulting list (if multicast is supported on the platform).</p> <p>If this list is empty, all the allowed interfaces may potentially be used for multicast.</p> <p>You must manage the memory of the list. The memory may be freed after the <i>DomainParticipant</i> is deleted.</p> <p>Default: empty list that represents all available interfaces</p>
parent. deny_multicast_interfaces_list	<p>A list of strings, each identifying a range of interface addresses or an interface name. If the list is non-empty, deny the use of those interfaces for multicast.</p> <p>Interfaces should be specified as comma-separated strings, with each comma delimiting an interface.</p> <p>This "black" list is applied after the <a href="#">parent.allow_multicast_interfaces_list above</a> list and filters out the interfaces that should <i>not</i> be used for multicast. The final resulting list will be those interfaces that—if multicast is available—will be used for multicast sends.</p> <p>You must manage the memory of the list. The memory may be freed after the <i>DomainParticipant</i> is deleted.</p> <p>Default: empty list that represents no denied interfaces</p>

Table 51.2 Properties for the Builtin UDPv4 Transport

Property Name (prefix with 'dds.transport.UDPv4.builtin.')	Property Value Description
send_socket_buffer_size	<p>Size in bytes of the send buffer of a socket used for sending. On most operating systems, <b>setsockopt()</b> will be called to set the SENDBUF to the value of this parameter.</p> <p>This value must be greater than or equal to the property, <a href="#">parent.message_size_max on page 961</a>. The maximum value is operating system-dependent.</p> <p>If -1, <b>setsockopt()</b> (or equivalent) will not be called to size the send buffer of the socket. The transport will use the OS default.</p> <p>Default: 131072</p>
recv_socket_buffer_size	<p>Size in bytes of the receive buffer of a socket used for receiving. On most operating systems, <b>setsockopt()</b> will be called to set the RECVBUF to the value of this parameter.</p> <p>This value must be greater than or equal to the property, <a href="#">parent.message_size_max on page 961</a>. The maximum value is operating system-dependent.</p> <p>If -1, <b>setsockopt()</b> (or equivalent) will not be called to size the receive buffer of the socket. The transport will use the OS default.</p> <p>Default: 131072</p>
unicast_enabled	<p>Allows the transport plugin to use unicast UDP for sending and receiving. By default, it will be turned on. Also by default, it will use all the allowed network interfaces that it finds up and running when the plugin is instanced.</p> <p>Can be 1 (enabled) or 0 (disabled).</p> <p>Default: 1</p>
multicast_enabled	<p>Allows the transport plugin to use multicast for sending and receiving. You can turn multicast on or off for this plugin. The default is that multicast is on and the plugin will use the all network interfaces allowed for multicast that it finds up and running when the plugin is instanced.</p> <p>Can be 1 (enabled) or 0 (disabled).</p> <p>Default: 1</p>
multicast_ttl	<p>Value for the time-to-live parameter for all multicast sends using this plugin. This is used to set the TTL of multicast packets sent by this transport plugin.</p> <p>Default: 1</p>
multicast_loopback_disabled	<p>Prevents the transport plugin from putting multicast packets onto the loopback interface.</p> <p>If disabled, then when sending multicast packets, do not put a copy on the loopback interface. This will prevent other applications on the same node (including itself) from receiving those packets.</p> <p><b>Note:</b> Windows CE does not support multicast loopback. This field is ignored for Windows CE targets.</p> <p>Default: 0, meaning multicast loopback is enabled. Turning off multicast loopback (setting to 1) may result in minor performance gains when using multicast.</p>

Table 51.2 Properties for the Builtin UDPv4 Transport

Property Name (prefix with 'dds.transport.UDPv4.builtin.')	Property Value Description
ignore_loopback_interface	<p>Prevents the transport plugin from using the IP loopback interface. Three values are allowed:</p> <ul style="list-style-type: none"> <li>0: Forces local traffic to be sent over loopback, even if a more efficient transport (such as shared memory) is installed (in which case traffic will be sent over both transports).</li> <li>1: Disables local traffic via this plugin. The IP loopback interface will not be used, even if no NICs are discovered. This is useful when you want applications running on the same node to use a more efficient transport (such as shared memory) instead of the IP loopback.</li> <li>-1: Automatic. Enables local traffic via this plugin. To avoid redundant traffic, <i>Connex</i> will selectively ignore the loopback destinations that are also reachable through shared memory.</li> </ul> <p>Default: -1</p>
DEPRECATED ignore_nonup_interfaces	<p>This property is only supported on Windows platforms with statically configured IP addresses.</p> <p>It allows/disallows the use of interfaces that are not reported as UP (by the operating system) in the UDPv4 transport. Two values are allowed:</p> <ul style="list-style-type: none"> <li>0: Allow interfaces that are reported as DOWN. <ul style="list-style-type: none"> <li>Setting this value to 0 supports communication scenarios in which interfaces are enabled after the participant is created. Once the interfaces are enabled, discovery will not occur until the participant sends the next periodic announcement (controlled by the parameter <code>participant_qos.discovery_config.participant_liveliness_assert_period</code>).</li> <li>To reduce discovery time, you may want to decrease the value of <code>participant_liveliness_assert_period</code>. For the above scenario, there is one caveat: non-UP interfaces must have a static IP assigned.</li> </ul> </li> <li>1: Do not allow interfaces that are reported as DOWN.</li> </ul> <p>Default: 1</p>
ignore_nonrunning_interfaces	<p>Prevents the transport plugin from using a network interface that is not reported as RUNNING by the operating system.</p> <p>The transport checks the flags reported by the operating system for each network interface upon initialization. An interface which is not reported as UP will not be used. This property allows the same check to be extended to the IFF_RUNNING flag implemented by some operating systems. The RUNNING flag is defined to mean that "all resources are allocated", and may be off if there is no link detected, e.g., the network cable is unplugged. Two values are allowed:</p> <ul style="list-style-type: none"> <li>0: Do not check the RUNNING flag when enumerating interfaces, just make sure the interface is UP.</li> <li>1: Check the flag when enumerating interfaces, and ignore those that are not reported as RUNNING. This can be used on some operating systems to cause the transport to ignore interfaces that are enabled but not connected to the network.</li> </ul> <p>By default this property is set to 1, so <i>Connex</i> will ignore non-running interfaces.</p>
DEPRECATED no_zero_copy	<p>Prevents the transport plugin from doing a zero copy.</p> <p>By default, this plugin will use the zero copy on OSs that offer it. While this is good for performance, it may sometime tax the OS resources in a manner that cannot be overcome by the application.</p> <p>The best example is if the hardware/device driver lends the buffer to the application itself. If the application does not return the loaned buffers soon enough, the node may error or malfunction. In case you cannot re-configure the hardware, device driver, or the OS to allow the zero-copy feature to work for your application, you may have no choice but to turn off zero-copy.</p> <p>By default this is set to 0, so <i>Connex</i> will use the zero-copy API if offered by the OS.</p>

Table 51.2 Properties for the Builtin UDPv4 Transport

Property Name (prefix with 'dds.transport.UDPv4.builtin.')	Property Value Description
send_blocking	<p>Controls the blocking behavior of send sockets. <b>CHANGING THIS FROM THE DEFAULT CAN CAUSE SIGNIFICANT PERFORMANCE PROBLEMS.</b> Currently two values are defined:</p> <ul style="list-style-type: none"> <li>• 1 (NDDS_TRANSPORT_UDP_BLOCKING_ALWAYS): Sockets are blocking (default socket options for operating system).</li> <li>• 0 (NDDS_TRANSPORT_UDP_BLOCKING_NEVER): Sockets are modified to make them non-blocking. <b>This may cause significant performance problems.</b></li> </ul> <p>Default: 1</p>
transport_priority_mask	<p>Mask for the transport priority field. This is used in conjunction with <a href="#">transport_priority_mapping_low</a> and <a href="#">transport_priority_mapping_high</a> to define the mapping from the <a href="#">47.26 TRANSPORT_PRIORITY QosPolicy on page 856</a> to the IPv4 TOS field. Defines a contiguous region of bits in the 32-bit transport priority value that is used to generate values for the IPv4 TOS field on an outgoing socket.</p> <p>For example, the value 0x0000ff00 causes bits 9-16 (8 bits) to be used in the mapping. The value will be scaled from the mask range (0x0000 - 0xff00 in this case) to the range specified by low and high.</p> <p>If the mask is set to zero, then the transport will not set IPv4 TOS for send sockets.</p> <p>Default: 0</p>
transport_priority_mapping_low	<p>Sets the low and high values of the output range to IPv4 TOS.</p> <p>These values are used in conjunction with <a href="#">transport_priority_mask</a> to define the mapping from the <a href="#">47.26 TRANSPORT_PRIORITY QosPolicy on page 856</a> to the IPv4 TOS field. Defines the low and high values of the output range for scaling.</p>
transport_priority_mapping_high	<p>Note that IPv4 TOS is generally an 8-bit value.</p> <p>Default: 0 for <a href="#">transport_priority_mapping_low</a> and 0xFF for <a href="#">transport_priority_mapping_high</a></p>
send_ping	<p>This property specifies whether to send a PING message before commencing the discovery process. On certain operating systems or with certain switches the initial UDP packet, configuring the ARP table, was unfortunately dropped. To avoid dropping the initial RTPS discovery sample, a PING message is sent to preconfigure the ARP table in those environments.</p> <p>Default: 1</p>
interface_poll_period	<p>Specifies the period in milliseconds to query for changes in the state of all the interfaces.</p> <p>When possible, the detection of an IP address changes is done asynchronously using the APIs offered by the underlying OS. If there is no mechanism to do that, the detection will use a polling strategy where the polling period can be configured by setting this property.</p> <p>Default: 500</p>
reuse_multicast_receive_resource	<p>Controls whether or not to reuse receive resources. Setting this to 0 (FALSE) prevents multicast crosstalk by uniquely configuring a port and creating a receive thread for each multicast group address.</p> <p>Affects Linux systems only; ignored for non-Linux systems.</p> <p>Default: 1</p>

Table 51.2 Properties for the Builtin UDPv4 Transport

Property Name (prefix with 'dds.transport.UDPv4.builtin.')	Property Value Description
protocol_overhead_max	<p>Maximum size in bytes of protocol overhead, including headers.</p> <p>This value is the maximum size, in bytes, of protocol-related overhead. Normally, the overhead accounts for UDP and IP headers. The default value is set to accommodate the most common UDP/IP header size.</p> <p>Note that when <a href="#">parent.message_size_max on page 961</a> plus this overhead is larger than the UDPv4 maximum message size (65535 bytes), the middleware will automatically reduce the effective <b>message_size_max</b> to 65535 minus this overhead.</p> <p>Default: 28</p>
disable_interface_tracking	<p>Disables detection of network interface changes.</p> <p>By default, network interfaces changes are propagated in the form of locators to other applications. This is done to support IP mobility scenarios. For example, you could start an application with Wi-Fi and move to a wired connection. In order to continue communicating with other applications this interface change must be propagated.</p> <p>In 5.0 and earlier versions of the product, IP mobility scenarios were not supported. Applications using 5.2 will report errors if they detect locator changes in a <i>DataWriter</i> or <i>DataReader</i>.</p> <p>You can disable the notification and propagation of interface changes by setting this property to 1. This way, an interface change in a newer application will not trigger errors in an application running 5.2 GAR or earlier. Of course, this will prevent the new application from being able to detect network interface changes.</p>
public_address	<p>Public IP address associated with the transport instantiation.</p> <p>Setting the public IP address is only necessary to support communication over WAN that involves Network Address Translation (NAT).</p> <p>Typically, the address is the public address of the IP NAT router that provides access to the WAN.</p> <p>By default, the <i>DomainParticipant</i> creating the transport will announce the IP addresses obtained from the NICs to other <i>DomainParticipants</i> in the system.</p> <p>When this property is set, the <i>DomainParticipant</i> will announce the IP address corresponding to the property value instead of the LAN IP addresses associated with the NICs.</p> <p>Notes:</p> <p>Setting this property is necessary, but is not a sufficient condition for sending and receiving data over the WAN. You must also configure the IP NAT router to allow UDP traffic and to map the public IP address specified by this property to the <i>DomainParticipant's</i> private LAN IP address. This is typically done with one of these mechanisms:</p> <ul style="list-style-type: none"> <li>• Port Forwarding: You must map the private ports used to receive discovery and user data traffic to the corresponding public ports (see <a href="#">Table 44.13 DDS_RtpsWellKnownPorts_t</a>). Public and private ports must be the same since the transport does not allow you to change the mapping.</li> <li>• 1:1 NAT: You must add a 1:1 NAT entry that maps the public IP address specified in this property to the private LAN IP address of the <i>DomainParticipant</i>.</li> </ul> <p>By setting this property, the <i>DomainParticipant</i> only announces its public IP address to other <i>DomainParticipants</i>. Therefore, communication with <i>DomainParticipants</i> within the LAN that are running on different nodes will not work unless the NAT router is configured to enable NAT reflection (hairpin NAT).</p> <p>There is another way to achieve simultaneous communication with <i>DomainParticipants</i> running in the LAN and WAN, that does not require hairpin NAT. This way uses a gateway application such as RTI Routing Service to provide access to the WAN.</p> <p>Default: NULL (the transport uses the IP addresses obtained from the NICs)</p>

Table 51.2 Properties for the Builtin UDPv4 Transport

Property Name (prefix with 'dds.transport.UDPv4.builtin.')	Property Value Description
use_checksum	<p>This property specifies whether the UDP checksum will be computed. On Windows and Linux systems, the UDP checksum will not be set when use_checksum is set to 0. This is useful when RTPS protocol statistics related to corrupted messages need to be collected through the operation <code>get_participant_protocol_status()</code> (see <a href="#">16.3.14 Getting Participant Protocol Status on page 105</a>).</p> <p>Default: 1</p>
force_interface_poll_detection	<p>This property forces the interface tracker to use a polling method to detect changes to the network interfaces in IP mobility scenarios. It only applies to operating systems that support asynchronous notifications of interface changes.</p> <p>If set to TRUE, the interface tracker will use a polling method that queries the interfaces periodically to detect the changes. If set to FALSE, the interface tracker will use the operating system's default method.</p> <p>Basically, this property allows you—for an operating system that supports asynchronous notification—to use the polling method instead.</p> <p>Default: FALSE</p>
join_multicast_group_timeout	<p>Windows only.</p> <p>On Windows, a network interface may be detected before it is allowed to join a multicast group address. This property adjusts how much time (in milliseconds) to wait for the ADD_MEMBERSHIP multicast operation to succeed before withdrawing.</p> <p>Default: 5000</p>
property_validation_action	<p>By default, property names given in the <a href="#">47.19 PROPERTY QosPolicy (DDS Extension) on page 837</a> are validated to avoid using incorrect or unknown names (for example, due to a typo). This property configures the validation of the property names associated with the transport:</p> <ul style="list-style-type: none"> <li>• VALIDATION_ACTION_EXCEPTION: validate the properties. Upon failure, log errors and fail.</li> <li>• VALIDATION_ACTION_SKIP: skip validation.</li> <li>• VALIDATION_ACTION_WARNING: validate the properties. Upon failure, log warnings and do not fail.</li> </ul> <p>If this property is not set, the property validation behavior will be the same as that of the <i>DomainParticipant</i>, which by default is VALIDATION_ACTION_EXCEPTION. See <a href="#">47.19.1 Property Validation on page 840</a> for more information.</p>
thread_name_prefix	<p>You can set this field with your own value, to help you identify the transport thread in a way that's meaningful to you. Do not exceed 8 characters.</p> <p>If you do not set this field, <i>Connex</i> creates the following prefix:</p> <pre>'r' + 'Tr' + participant identifier + '\0'</pre> <p>Where 'r' indicates this is a thread from RTI, 'Tr' indicates the thread is related to a transport, and participant identifier contains 5 characters as follows:</p> <ul style="list-style-type: none"> <li>• If <b>participant_name</b> is set: The participant identifier will be the first 3 characters and the last 2 characters of the <b>participant_name</b>.</li> <li>• If <b>participant_name</b> is not set, then the identifier is computed as <b>domain_id</b> (3 characters) followed by <b>participant_id</b> (2 characters).</li> <li>• If <b>participant_name</b> is not set and the <b>participant_id</b> is set to -1 (default value), then the participant identifier is computed as the last 5 digits of the <b>rtps_instance_id</b> in the participant GUID.</li> </ul> <p>See <a href="#">Chapter 72 Identifying Threads Used by Connex on page 1196</a>.</p>

Table 51.3 Properties for Builtin UDPv6 Transport

Property Name (prefix with 'dds.transport.UDPv6.builtin.')	Description
parent.properties_bitmap	<p>A bitmap that defines various properties of the transport to the <i>Connex</i> core.</p> <p>Currently, the only property supported is whether or not the transport plugin will always loan a buffer when <i>Connex</i> tries to receive a message using the plugin. This is in support of a zero-copy interface.</p>
parent.gather_send_buffer_count_max	<p>Specifies the maximum number of buffers that <i>Connex</i> can pass to the <code>send()</code> method of a transport plugin.</p> <p>The transport plugin <code>send()</code> API supports a gather-send concept, where the <code>send()</code> call can take several discontiguous buffers, assemble and send them in a single message. This enables <i>Connex</i> to send a message from parts obtained from different sources without first having to copy the parts into a single contiguous buffer.</p> <p>However, most transports that support a gather-send concept have an upper limit on the number of buffers that can be gathered and sent. Setting this value will prevent <i>Connex</i> from trying to gather too many buffers into a send call for the transport plugin.</p> <p><i>Connex</i> requires all transport-plugin implementations to support a gather-send of least a minimum number of buffers. This minimum number is <code>NDDS_TRANSPORT_PROPERTY_GATHER_SEND_BUFFER_COUNT_MIN</code>.</p>
parent.message_size_max	<p>The maximum size of a message in bytes that can be sent or received by the transport plugin. Above this size, DDS-level fragmentation will occur. See <a href="#">34.3 Large Data Fragmentation on page 524</a>.</p> <p>This value must be set before the transport plugin is registered, so that <i>Connex</i> can properly use the plugin.</p> <p>Default for Integrity platforms: 9196</p> <p>Default for non-Integrity platforms: 65487</p>
parent.allow_interfaces_list	<p>A list of strings, each identifying a range of interface addresses or an interface name. Interfaces must be specified as comma-separated strings, with each comma delimiting an interface. See <a href="#">51.6.2 Formatting Rules for IPv6 'Allow' and 'Deny' Address Lists on page 978</a>.</p> <p>If the list is non-empty, this "white" list is applied before the <a href="#">parent.deny_interfaces_list</a> below list. The <i>DomainParticipant</i> will use the resulting list of interfaces to inform its remote participant(s) about which unicast addresses may be used to send data to that <i>DomainParticipant</i>. The resulting list also controls the interfaces over which the <i>DomainParticipant</i> will send multicast traffic to the remote <i>DomainParticipants</i> (if multicast is supported on the platform).</p> <p><b>Note:</b> This property does not affect the interfaces that the transport uses to send unicast data <i>from</i> that <i>DomainParticipant</i>. That decision is made by the OS based on the destination address.</p> <p>You must manage the memory of the list. The memory may be freed after the <i>DomainParticipant</i> is deleted.</p> <p>The left-to-right order of this list matters if you are using the <code>max_interface_count</code> to limit the allowable interfaces further. See <code>max_interface_count</code>.</p> <p>Default: empty list that represents all available interfaces</p>
parent.deny_interfaces_list	<p>A list of strings, each identifying a range of interface addresses or an interface name. If the list is non-empty, deny the use of these interfaces. Interfaces must be specified as comma-separated strings, with each comma delimiting an interface. See <a href="#">51.6.2 Formatting Rules for IPv6 'Allow' and 'Deny' Address Lists on page 978</a>.</p> <p>This "black" list is applied after the <a href="#">parent.allow_interfaces_list</a> above list and filters out the interfaces that should <i>not</i> be used. The resulting list also controls the interfaces over which the <i>DomainParticipant</i> will send multicast traffic to the remote <i>DomainParticipants</i> (if multicast is supported on the platform).</p> <p><b>Note:</b> This property does not affect the interfaces that the transport uses to send unicast data <i>from</i> a <i>DomainParticipant</i>. That decision is made by the OS based on the destination address.</p> <p>You must manage the memory of the list. The memory may be freed after the <i>DomainParticipant</i> is deleted.</p> <p>Default: empty list that represents no denied interfaces</p>

Table 51.3 Properties for Builtin UDPv6 Transport

Property Name (prefix with 'dds.transport.UDPv6.builtin.')	Description
parent.max_interface_count	<p>How many of the addresses in your allowed interfaces list are used, at most, at any time.</p> <p>This feature is useful if you want to control the network interfaces on which your <i>DomainParticipants</i> receive data. For example, if you have one wired and one wireless interface in your allowed interfaces list <i>both</i> up and running, and <b>max_interface_count</b> is set to 1, the <i>DomainParticipant</i> will receive data over the interface you list first in the <b>allow_interfaces_list</b>—for example, the wired one. If the wired interface is not in use (for example, the device is undocked), then the <i>DomainParticipant</i> will receive data only over the next available up-and-running interface in your <b>allow_interfaces_list</b>, which would be the wireless one.</p> <p><i>Connex</i>t selects the preferred interface(s) by iterating over the list of allowed interfaces until the first <b>max_interfaces_count</b> of active interfaces encountered are announced. The order of iteration is left to right as specified in the <b>allow_interfaces_list</b> setting.</p> <p>This setting applies only if the <b>allow_interfaces_list</b> is not empty.</p> <p>The <b>max_interface_count</b> setting does not consider end-to-end connectivity to select interfaces. The decision is based purely on whether interfaces are up or down in a node. Therefore, this feature is not intended to be used in the following scenarios:</p> <ul style="list-style-type: none"> <li>• A <i>DomainParticipant</i> is not reachable by other <i>DomainParticipants</i> in all the interfaces in the <b>allow_interfaces_list</b>. This could occur if the <i>DomainParticipant</i> is in different subnets, and some of these subnets cannot be reached by other <i>DomainParticipants</i>.</li> <li>• End-to-end connectivity issues lead to situations in which the interfaces selected after applying <b>max_interface_count</b> cannot be reached by other <i>DomainParticipants</i>.</li> </ul> <p>This feature also affects multicast traffic by limiting the interfaces over which a <i>DomainParticipant</i> sends multicast traffic. The <b>(allow/deny)_multicast_interfaces_list</b> applies to the interfaces selected by using the <b>max_interfaces_count</b> property.</p> <p><b>Note:</b> If a pattern string in the <b>allow_interfaces_list</b> matches multiple interface addresses, and <b>max_interface_count</b> is set to a finite value, the order for the matching allowed interfaces is decided based on the order in which the operating system provides these interfaces.</p> <p>Default: LENGTH_UNLIMITED Range: [1, LENGTH_UNLIMITED]</p>
parent.allow_multicast_interfaces_list	<p>A list of strings, each identifying a range of interface addresses or an interface name. If the list is non-empty, allow the use of multicast only these interfaces; otherwise allow the use of all the allowed interfaces.</p> <p>Interfaces must be specified as comma-separated strings, with each comma delimiting an interface. See <a href="#">51.6.2 Formatting Rules for IPv6 'Allow' and 'Deny' Address Lists on page 978</a>.</p> <p>This list sub-selects from the allowed interfaces that are obtained after applying the <a href="#">parent.allow_interfaces_list on the previous page</a> "white" list <i>and</i> the <a href="#">parent.deny_interfaces_list on the previous page</a> "black" list. Finally, the <a href="#">parent.deny_multicast_interfaces_list below</a> is applied. Multicast output will be sent and may be received over the interfaces in the resulting list (if multicast is supported on the platform).</p> <p>If this list is empty, all the allowed interfaces may potentially be used for multicast.</p> <p>You must manage the memory of the list. The memory may be freed after the <i>DomainParticipant</i> is deleted.</p>
parent.deny_multicast_interfaces_list	<p>A list of strings, each identifying a range of interface addresses or an interface name. If the list is non-empty, deny the use of those interfaces for multicast.</p> <p>Interfaces must be specified as comma-separated strings, with each comma delimiting an interface. See <a href="#">51.6.2 Formatting Rules for IPv6 'Allow' and 'Deny' Address Lists on page 978</a>.</p> <p>This "black" list is applied after the <a href="#">parent.allow_multicast_interfaces_list above</a> list and filters out the interfaces that should <i>not</i> be used for multicast. Multicast output will be sent and may be received over the interfaces in the resulting list (if multicast is supported on the platform).</p> <p>You must manage the memory of the list. The memory may be freed after the <i>DomainParticipant</i> is deleted.</p>

Table 51.3 Properties for Builtin UDPv6 Transport

Property Name (prefix with 'dds.transport.UDPv6.builtin.')	Description
send_socket_buffer_size	<p>Size in bytes of the send buffer of a socket used for sending. On most operating systems, <b>setsockopt()</b> will be called to set the SENDBUF to the value of this parameter.</p> <p>This value must be greater than or equal to <b>parent.message_size_max</b>. The maximum value is operating system-dependent.</p> <p>If -1, <b>setsockopt()</b> (or equivalent) will not be called to size the send buffer of the socket. The transport will use the OS default.</p> <p>Default: 131072</p>
recv_socket_buffer_size	<p>Size in bytes of the receive buffer of a socket used for receiving. On most operating systems, <b>setsockopt()</b> will be called to set the RECVBUF to the value of this parameter.</p> <p>This value must be greater than or equal to <b>parent.message_size_max</b>. The maximum value is operating system-dependent.</p> <p>If -1, <b>setsockopt()</b> (or equivalent) will not be called to size the receive buffer of the socket. The transport will use the OS default.</p> <p>Default: 131072</p>
unicast_enabled	<p>Allows the transport plugin to use unicast UDP for sending and receiving. By default, it will be turned on (1). Also by default, it will use all the allowed network interfaces that it finds up and running when the plugin is instantiated.</p> <p>Can be 1 (enabled) or 0 (disabled).</p>
multicast_enabled	<p>Allows the transport plugin to use multicast for sending and receiving.</p> <p>You can turn multicast UDP on or off for this plugin. By default, it will be turned on (1). Also by default, it will use the all network interfaces allowed for multicast that it finds up and running when the plugin is instantiated.</p> <p>Can be 1 (enabled) or 0 (disabled).</p>
multicast_ttl	<p>Value for the time-to-live parameter for all multicast sends using this plugin.</p> <p>This is used to set the TTL of multicast packets sent by this transport plugin</p>
multicast_loopback_disabled	<p>Prevents the transport plugin from putting multicast packets onto the loopback interface.</p> <p>If disabled, then when sending multicast packets, <i>Connex</i> will not put a copy on the loopback interface. This will prevent applications on the same node (including itself) from receiving those packets.</p> <p>This is set to 0 by default, meaning multicast loopback is enabled. Disabling multicast loopback off (setting this value to 1) may result in minor performance gains when using multicast.</p>
ignore_loopback_interface	<p>Prevents the transport plugin from using the IP loopback interface. Three values are allowed:</p> <p>0: Enable local traffic via this plugin. This plugin will only use and report the IP loopback interface if there are no other network interfaces (NICs) up on the system.</p> <p>1: Disable local traffic via this plugin. Do not use the IP loopback interface even if no NICs are discovered. This is useful when you want applications running on the same node to use a more efficient plugin like Shared Memory instead of the IP loopback.</p> <p>-1: Automatic. Enables local traffic via this plugin. To avoid redundant traffic, <i>Connex</i> will selectively ignore the loopback destinations that are also reachable through shared memory.</p>

Table 51.3 Properties for Builtin UDPv6 Transport

Property Name (prefix with 'dds.transport.UDPv6.builtin.')	Description
ignore_nonrunning_interfaces	<p>Prevents the transport plugin from using a network interface that is not reported as RUNNING by the operating system.</p> <p>The transport checks the flags reported by the operating system for each network interface upon initialization. An interface which is not reported as UP will not be used. This property allows the same check to be extended to the IFF_RUNNING flag implemented by some operating systems. The RUNNING flag is defined to mean that "all resources are allocated", and may be off if there is no link detected, e.g., the network cable is unplugged. Two values are allowed:</p> <ul style="list-style-type: none"> <li>• 0: Do not check the RUNNING flag when enumerating interfaces, just make sure the interface is UP.</li> <li>• 1: Check the flag when enumerating interfaces, and ignore those that are not reported as RUNNING. This can be used on some operating systems to cause the transport to ignore interfaces that are enabled but not connected to the network.</li> </ul> <p>By default this property is set to 1, so <i>Connex</i>t will ignore non-running interfaces.</p>
DEPRECATED no_zero_copy	<p>Prevents the transport plugin from doing a zero copy.</p> <p>By default, this plugin will use the zero copy on OSs that offer it. While this is good for performance, it may sometime tax the OS resources in a manner that cannot be overcome by the application.</p> <p>The best example is if the hardware/device driver lends the buffer to the application itself. If the application does not return the loaned buffers soon enough, the node may error or malfunction. In case you cannot re-configure the H/W, device driver, or the OS to allow the zero-copy feature to work for your application, you may have no choice but to turn off zero-copy.</p> <p>By default this is set to 0, so <i>Connex</i>t will use the zero-copy API if offered by the OS.</p>
send_blocking	<p>Controls the blocking behavior of send sockets. <b>CHANGING THIS FROM THE DEFAULT CAN CAUSE SIGNIFICANT PERFORMANCE PROBLEMS.</b> Currently two values are defined:</p> <ul style="list-style-type: none"> <li>• 1 (NDDS_TRANSPORT_UDP_BLOCKING_ALWAYS): Sockets are blocking (default socket options for Operating System).</li> <li>• 0 (NDDS_TRANSPORT_UDP_BLOCKING_NEVER): Sockets are modified to make them non-blocking. <b>This may cause significant performance problems.</b></li> </ul> <p>Default: 1</p>
enable_v4mapped	<p>Specifies whether the UDPv6 transport will process IPv4 addresses.</p> <p>Set this to 1 to turn on processing of IPv4 addresses. Note that this may make it incompatible with use of the UDPv4 transport within the same <i>DomainParticipant</i>.</p>
transport_priority_mask	<p>Sets a mask for use of transport priority field.</p> <p>If transport priority mapping is supported on the platform<sup>1</sup>, this mask is used in conjunction with <a href="#">transport_priority_mapping_low on the next page</a> and <a href="#">transport_priority_mapping_high on the next page</a> to define the mapping from the DDS transport priority <a href="#">47.26 TRANSPORT_PRIORITY QosPolicy on page 856</a> to the IPv6 TCLASS field.</p> <p>Defines a contiguous region of bits in the 32-bit transport priority value that is used to generate values for the IPv6 TCLASS field on an outgoing socket.</p> <p>For example, the value 0x0000ff00 causes bits 9-16 (8 bits) to be used in the mapping. The value will be scaled from the mask range (0x0000 - 0xff00 in this case) to the range specified by low and high.</p> <p>If the mask is set to zero, then the transport will not set IPv6 TCLASS for send sockets.</p>

<sup>1</sup>See the [RTI Connex Core Libraries Platform Notes](#) to find out if the transport priority is supported on a specific platform.

Table 51.3 Properties for Builtin UDPv6 Transport

Property Name (prefix with 'dds.transport.UDPv6.builtin.')	Description
transport_priority_mapping_low	Sets the low and high values of the output range to IPv6 TCLASS.
transport_priority_mapping_high	These values are used in conjunction with <a href="#">transport_priority_mask</a> on the previous page to define the mapping from DDS transport priority to the IPv6 TCLASS field. Defines the low and high values of the output range for scaling. Note that IPv6 TCLASS is generally an 8-bit value.
send_ping	This property specifies whether to send a PING message before commencing the discovery process. On certain operating systems or with certain switches the initial UDP packet, configuring the ARP table, was unfortunately dropped. To avoid dropping the initial RTPS discovery sample, a PING message is sent to preconfigure the ARP table in those environments.
interface_poll_period	See <a href="#">interface_poll_period</a> on page 966 in <a href="#">Table 51.2 Properties for the Builtin UDPv4 Transport</a>
reuse_multicast_receive_resource	This property controls whether or not to reuse multicast receive resources.
protocol_overhead_max	This value is the maximum size, in bytes, of protocol-related overhead. Normally, the overhead accounts for UDP and IP headers. The default value is set to accommodate the most common UDP/IP header size. Note that when <b>NDDS_Transport_Property_t::message_size_max</b> plus this overhead is larger than the <a href="#">parent.message_size_max</a> on page 969 (65535 bytes), the middleware will automatically reduce the effective <b>message_size_max</b> , to 65535 minus this overhead.
disable_interface_tracking	Disables detection of network interface changes. See <a href="#">disable_interface_tracking</a> in <a href="#">Table 51.2 Properties for the Builtin UDPv4 Transport</a> .
public_address	See <a href="#">public_address</a> in <a href="#">Table 51.2 Properties for the Builtin UDPv4 Transport</a> .
force_interface_poll_detection	This property forces the interface tracker to use a polling method to detect changes to the network interfaces in IP mobility scenarios. It only applies to operating systems that support asynchronous notifications of interface changes. If set to TRUE, the interface tracker will use a polling method that queries the interfaces periodically to detect the changes. If set to FALSE, the interface tracker will use the operating system's default method. Basically, this property allows you—for an operating system that supports asynchronous notification—to use the polling method instead. Default: FALSE
join_multicast_group_timeout	Windows only. On Windows, a network interface may be detected before it is allowed to join a multicast group address. This property adjusts how much time (in milliseconds) to wait for the ADD_MEMBERSHIP multicast operation to succeed before withdrawing. Default: 5000

Table 51.3 Properties for Builtin UDPv6 Transport

Property Name (prefix with 'dds.transport.UDPv6.builtin.')	Description
property_validation_action	<p>By default, property names given in the <a href="#">47.19 PROPERTY QosPolicy (DDS Extension) on page 837</a> are validated to avoid using incorrect or unknown names (for example, due to a typo). This property configures the validation of the property names associated with the transport:</p> <ul style="list-style-type: none"> <li>• VALIDATION_ACTION_EXCEPTION: validate the properties. Upon failure, log errors and fail.</li> <li>• VALIDATION_ACTION_SKIP: skip validation.</li> <li>• VALIDATION_ACTION_WARNING: validate the properties. Upon failure, log warnings and do not fail.</li> </ul> <p>If this property is not set, the property validation behavior will be the same as that of the <i>DomainParticipant</i>, which by default is VALIDATION_ACTION_EXCEPTION. See <a href="#">47.19.1 Property Validation on page 840</a> for more information.</p>
thread_name_prefix	<p>You can set this field with your own value, to help you identify the transport thread in a way that's meaningful to you. Do not exceed 8 characters.</p> <p>If you do not set this field, <i>Connex</i> creates the following prefix:</p> <pre>'r' + 'Tr' + participant identifier + '\0'</pre> <p>Where 'r' indicates this is a thread from RTI, 'Tr' indicates the thread is related to a transport, and participant identifier contains 5 characters as follows:</p> <ul style="list-style-type: none"> <li>• If <b>participant_name</b> is set: The participant identifier will be the first 3 characters and the last 2 characters of the <b>participant_name</b>.</li> <li>• If <b>participant_name</b> is not set, then the identifier is computed as <b>domain_id</b> (3 characters) followed by <b>participant_id</b> (2 characters).</li> <li>• If <b>participant_name</b> is not set and the <b>participant_id</b> is set to -1 (default value), then the participant identifier is computed as the last 5 digits of the <b>rtps_instance_id</b> in the participant GUID.</li> </ul> <p>See <a href="#">Chapter 72 Identifying Threads Used by Connex on page 1196</a>.</p>

Table 51.4 Properties for Builtin Shared-Memory Transport

Property Name (prefix with 'dds.transport.shmem.builtin.')	Property Value Description
parent.properties_bitmap	<p>A bitmap that defines various properties of the transport to the <i>Connex</i> core.</p> <p>Currently, the only property supported is whether or not the transport plugin will always loan a buffer when <i>Connex</i> tries to receive a message using the plugin. This is in support of a zero-copy interface.</p>
parent.gather_send_buffer_count_max	<p>Specifies the maximum number of buffers that <i>Connex</i> can pass to the <b>send()</b> method of a transport plugin.</p> <p>The transport plugin <b>send()</b> API supports a gather-send concept, where the <b>send()</b> call can take several discontinuous buffers, assemble and send them in a single message. This enables <i>Connex</i> to send a message from parts obtained from different sources without first having to copy the parts into a single contiguous buffer.</p> <p>However, most transports that support a gather-send concept have an upper limit on the number of buffers that can be gathered and sent. Setting this value will prevent <i>Connex</i> from trying to gather too many buffers into a send call for the transport plugin.</p> <p><i>Connex</i> requires all transport-plugin implementations to support a gather-send of least a minimum number of buffers. This minimum is <code>NDDS_TRANSPORT_PROPERTY_GATHER_SEND_BUFFER_COUNT_MIN</code>.</p>
parent.message_size_max	<p>The maximum size of a message in bytes that can be sent or received by the transport plugin. Above this size, DDS-level fragmentation will occur. See <a href="#">34.3 Large Data Fragmentation on page 524</a>.</p> <p>This value must be set before the transport plugin is registered, so that <i>Connex</i> can properly use the plugin.</p> <p>Default for Integrity platforms: 9216</p> <p>Default for non-Integrity platforms: 65536</p>
parent.allow_interfaces_list	<p>Not applicable to the Shared-Memory Transport</p>
parent.deny_interfaces_list	
parent.max_interface_count	
parent.allow_multicast_interfaces_list	
parent.deny_multicast_interfaces_list	
received_message_count_max	<p>Number of messages that can be buffered in the receive queue. This is the maximum number of messages that can be buffered in a RecvResource of the Transport Plugin. This does not guarantee that the Transport-Plugin will actually be able to buffer <b>received_message_count_max</b> messages of the maximum size set in <a href="#">parent.message_size_max</a> above.</p> <p>The total number of bytes that can be buffered for a RecvResource is actually controlled by <a href="#">receive_buffer_size</a> on the next page.</p>

Table 51.4 Properties for Builtin Shared-Memory Transport

Property Name (prefix with 'dds.transport.shmem.builtin.')	Property Value Description
receive_buffer_size	<p>The total number of bytes that can be buffered in the receive queue.</p> <p>This number controls how much memory is allocated by the plugin for the receive queue (on a per RecvResource basis). The actual number of bytes allocated is:</p> $\text{size} = \text{receive\_buffer\_size} + \text{message\_size\_max} + \text{received\_message\_count\_max} * \text{fixedOverhead}$ <p>where <i>fixedOverhead</i> is some small number of bytes used by the queue data structure.</p> <p>If <b>receive_buffer_size</b> &lt; (<b>message_size_max</b> * <b>received_message_count_max</b>), the transport plugin will not be able to store <b>received_message_count_max</b> messages of size <b>message_size_max</b>.</p> <p>If <b>receive_buffer_size</b> &gt; (<b>message_size_max</b> * <b>received_message_count_max</b>), then there will be memory allocated that cannot be used by the plugin and thus wasted.</p> <p>To optimize memory usage, specify a receive queue size less than that required to hold the maximum number of messages which are all of the maximum size.</p> <p>In most situations, the average message size may be far less than the maximum message size. So for example, if the maximum message size is 64K bytes, and you configure the plugin to buffer at least 10 messages, then 640K bytes of memory would be needed if all messages were 64K bytes. Should this be desired, then <b>receive_buffer_size</b> should be set to 640K bytes.</p> <p>However, if the average message size is only 10K bytes, then you could set the <b>receive_buffer_size</b> to 100K bytes. This allows you to optimize the memory usage of the plugin for the average case and yet allow the plugin to handle the extreme case.</p> <p>The queue will always be able to hold 1 message of <b>message_size_max</b> bytes, regardless of the value of <b>receive_buffer_size</b>.</p>
host_id	<p>Host ID used to generate the shared memory transport network address.</p> <p>Shared memory transport has an associated network address to communicate with other <i>DomainParticipants</i> within the same node. This network address is typically generated from the host ID, a unique host identifier. <i>Connex</i>t computes this host ID based on the hardware address, or media access control (MAC) address, of the first network interface found and the value of <b>rtps_auto_id_kind</b>.</p> <p>When set, this property forces the use of a specific host ID to generate the shared memory network address instead of computing it as described above. This property takes an unsigned integer value that is converted into the network address.</p> <p>This host ID should satisfy the following properties:</p> <ul style="list-style-type: none"> <li>• Should be unique across nodes. Otherwise, remote <i>DomainParticipants</i> may try to communicate using shared memory transport with <i>DomainParticipants</i> from a different node (which will not work).</li> <li>• Should be the same for all <i>DomainParticipants</i> within the same node that want to communicate using shared memory if <b>accept_unknown_peers</b> is set to FALSE or there are <i>DomainParticipants</i> in the system running a <i>Connex</i>t version previous to 6.0.0.</li> </ul> <p><b>Note:</b> This property is needed in very few scenarios: for example, when two different <i>Connex</i>t applications in the same node have <b>rtps_auto_id_kind</b> set to DDS RTPS_AUTO_ID_FROM_UUID, the first detected network interface is different for each application, and <b>accept_unknown_peers</b> is set to FALSE.</p>
enable_udp_debugging	<p>Enables UDP debugging when using shared memory. If set to '1', all shared memory traffic will be published to <b>udp_debugging_address::udp_debugging_port</b>, and the number of shared memory transport gather buffers will be the value of <b>parent.gather_send_buffer_count_max</b> or 16, whichever is smaller. Default: 0.</p>
udp_debugging_address	<p>IP address to which shared memory traffic will be published if <b>enable_udp_debugging</b> is set to '1'. Default: 239.255.1.2.</p>

**Table 51.4 Properties for Builtin Shared-Memory Transport**

Property Name (prefix with 'dds.transport.shmem.builtin.')	Property Value Description
udp_debugging_port	Port to which shared memory traffic will be published if <b>enable_udp_debugging</b> is set to '1'. Default: 7399.
use_530_from_uuid_locator	<p>This property only applies when the WireProtocol QoS policy (specifically <b>rtps_auto_id_kind</b>) is set to DDS_RTPS_AUTO_ID_FROM_UUID. If set to TRUE, the generated shared memory locator will be compatible with the locator created in version 5.3. If set to FALSE the generated shared memory locator will not be compatible, and communication will not occur. For more information, see the <i>Migration Guide</i> on the RTI Community Portal (<a href="https://community.rti.com/documentation">https://community.rti.com/documentation</a>).</p> <p>Default: FALSE</p>
property_validation_action	<p>By default, property names given in the <a href="#">47.19 PROPERTY QoS Policy (DDS Extension) on page 837</a> are validated to avoid using incorrect or unknown names (for example, due to a typo). This property configures the validation of the property names associated with the transport:</p> <ul style="list-style-type: none"> <li>• VALIDATION_ACTION_EXCEPTION: validate the properties. Upon failure, log errors and fail.</li> <li>• VALIDATION_ACTION_SKIP: skip validation.</li> <li>• VALIDATION_ACTION_WARNING: validate the properties. Upon failure, log warnings and do not fail.</li> </ul> <p>If this property is not set, the property validation behavior will be the same as that of the <i>DomainParticipant</i>, which by default is VALIDATION_ACTION_EXCEPTION. See <a href="#">47.19.1 Property Validation on page 840</a> for more information.</p>
thread_name_prefix	<p>You can set this field with your own value, to help you identify the transport thread in a way that's meaningful to you. Do not exceed 8 characters.</p> <p>If you do not set this field, <i>Connex</i>t creates the following prefix:</p> <p style="padding-left: 40px;">'r' + 'Tr' + participant identifier + '\0'</p> <p>Where 'r' indicates this is a thread from RTI, 'Tr' indicates the thread is related to a transport, and participant identifier contains 5 characters as follows:</p> <ul style="list-style-type: none"> <li>• If <b>participant_name</b> is set: The participant identifier will be the first 3 characters and the last 2 characters of the <b>participant_name</b>.</li> <li>• If <b>participant_name</b> is not set, then the identifier is computed as <b>domain_id</b> (3 characters) followed by <b>participant_id</b> (2 characters).</li> <li>• If <b>participant_name</b> is not set and the <b>participant_id</b> is set to -1 (default value), then the participant identifier is computed as the last 5 digits of the <b>rtps_instance_id</b> in the participant GUID.</li> </ul> <p>See <a href="#">Chapter 72 Identifying Threads Used by Connex</a>t on page 1196.</p>

### 51.6.1 Setting the Maximum Gather-Send Buffer Count for UDP Transports

To minimize memory copies, *Connex*t uses the "gather send" API that may be available on the transport.

Some operating systems limit the number of gather buffers that can be given to the gather-send function. This limits *Connex*t's ability to concatenate multiple DDS samples into a single network message. An example is the UDP transport's **sendmsg()** call, which on some OSs (such as Solaris) can only take 16 gather buffers, limiting the number of DDS samples that can be concatenated to five or six.

To match this limitation, *Connex* sets the UDP transport plug-ins' **gather\_send\_buffer\_count\_max** to 16 by default for all operating systems. This field is part of the **NDDS\_Transport\_Property\_t** structure.

- On VxWorks 5.5 operating systems, **gather\_send\_buffer\_count\_max** can be set as high as 63.
- On Windows and INTEGRITY operating systems, **gather\_send\_buffer\_count\_max** can be set as high as 128.
- On most other operating systems, **gather\_send\_buffer\_count\_max** can be set as high as 16.

If you are using an OS that allows more than 16 gather buffers for a **sendmsg()** call, you may increase the UDP transport plug-in's **gather\_send\_buffer\_count\_max** from the default up to your OS's limit (but no higher than 128).

For example, if your OS imposes a limit of 64 gather buffers, you may increase the **gather\_send\_buffer\_count\_max** up to 64. However, if your OS's gather-buffer limit is 1024, you may only increase the **gather\_send\_buffer\_count\_max** up to 128.

By changing **gather\_send\_buffer\_count\_max**, you can increase performance in the following situations:

- When a *DataWriter* is sending multiple packets to a *DataReader* either because the *DataReader* is a late-joiner and needs to catch up, or because several packets were dropped by the network or rejected and need to be resent. Changing the setting will help when the *DataWriter* needs to send or resend more than five or six packets at a time.
- If your application has more than five or six *DataWriters* or *DataReaders* in a participant. (In this case, the change will make the discovery process more efficient.)
- When using an asynchronous *DataWriter*, DDS samples are sent asynchronously by a separate thread. DDS samples may not be sent immediately, but may be queued instead, depending on the settings of the associated FlowController. If multiple DDS samples in the queue must be sent to the same destination, they will be coalesced into as few network packets as possible. The number of DDS samples that can be put in a single message is directly proportional to **gather\_send\_buffer\_count\_max**. Therefore, by maximizing **gather\_send\_buffer\_count\_max**, you can minimize the number of packets on the wire.

## 51.6.2 Formatting Rules for IPv6 ‘Allow’ and ‘Deny’ Address Lists

This section describes how to format the strings in the properties that create “allow” and “deny” lists:

- `dds.transport.UDPv6.builtin.parent.allow_interfaces_list` on page 962
- `dds.transport.UDPv6.builtin.parent.deny_interfaces_list` on page 962

- dds.transport.UDPv6.builtin. [parent.allow\\_multicast\\_interfaces\\_list](#) on page 963
- dds.transport.UDPv6.builtin. [parent.deny\\_multicast\\_interfaces\\_list](#) on page 963

These properties may contain a list of strings, each identifying a range of interface addresses or an interface name. Interfaces should be specified as comma-separated strings, with each comma delimiting an interface.

The strings can be addresses and patterns in IPv6 notation. They are case-insensitive.

They may contain a wildcard '\*' and can expand up to 4 digits in a block. The wildcard must be either leading or trailing (cannot be in the middle of the string). Multiple wildcards can be specified in a single filter, but only one wildcard can be specified per block (between colons). [Table 51.5 Examples of IPv6 Address Filters](#) shows some examples.

**Table 51.5 Examples of IPv6 Address Filters**

Example Filter	Equivalent Filters	Matches
*.*.*.*.*.*.*.*		
FE80::*	fe80::*, Fe80:0:0::*	
	Fe80:0:0:0:0:0:0:*	FE80:0000:0000:0000:0000:0000:xxxx:xxxx
FE80:aBC::202:2*:*2		FE80:0ABC:0000:0000:0202:2xxx:xxxx:xxx2

## 51.7 Installing Additional Builtin Transport Plugins with register\_transport()

After you create an instance of a transport plugin (see [51.4 Explicitly Creating Builtin Transport Plugin Instances on page 958](#)), you have to register it.

The builtin transports (UDPv4, UDPv6, and Shared Memory) are implicitly registered by default (if they are enabled via the [44.7 TRANSPORT\\_BUILTIN QosPolicy \(DDS Extension\) on page 725](#)). Therefore, you only need to explicitly register a builtin transport if you want an extra instance of it (suppose you want two UDPv4 transports, one with special settings).

The **register\_transport()** operation registers a transport plugin for use with a *DomainParticipant* and assigns it a network address. (Note: this operation is only available in the APIs other than Java or .NET. If you are using Java or .NET, use the Property QosPolicy to install additional transport plugins.)

```
NDDS_Transport_Handle_t NDDSTransportSupport::register_transport(
    DDSDomainParticipant * participant_in,
    NDDS_Transport_Plugin * transport_in,
    const DDS_StringSeq & aliases_in,
    const NDDS_Transport_Address_t & network_address_in)
```

Where:

- participant\_in** A non-NULL, disabled DomainParticipant.
- transport\_in** A non-NULL transport plugin that is currently not registered with another DomainParticipant.
- aliases\_in** A non-NULL sequence of strings used as aliases to refer to the transport plugin symbolically. The transport plugin will be "available for use" to an Entity contained in the DomainParticipant, if the transport alias list associated with the Entity contains one of these transport aliases. An empty alias list represents a WILDCARD and matches ALL aliases. See [51.7.2 Transport Aliases on the next page](#).
- network\_address\_in** The network address at which to register this transport plugin. The least significant transport\_in->property.address\_bit\_count will be truncated. The remaining bits are the network address of the transport plugin. See [51.7.3 Transport Network Addresses on page 982](#).

**Note:** You must ensure that the transport plugin instance is only used by one *DomainParticipant* at a time. See [51.7.1 Transport Lifecycles below](#).

Upon success, a valid non-NIL transport handle is returned, representing the association between the *DomainParticipant* and the transport plugin. If the transport cannot be registered, NDDS\_TRANSPORT\_HANDLE\_NIL is returned.

Note that a transport plugin's class name is automatically registered as an implicit alias for the plugin. Thus, a class name can be used to refer to all the transport plugin instances of that class.

The C and C++ APIs also have a operation to retrieve a registered transport plugin, **get\_transport\_plugin()**.

```
NDDS_Transport_Plugin* get_transport_plugin(
    DDSDomainParticipant* participant_in,
    const char* alias_in);
```

## 51.7.1 Transport Lifecycles

If you create and register a transport plugin with a *DomainParticipant*, you are responsible for deleting it by calling its destructor. Builtin transport plugins are automatically managed by *Connex* if they are implicitly registered through the TransportBuiltinQosPolicy.

User-created transport plugins must not be deleted while they are still in use by a *DomainParticipant*. This generally means that a user-created transport plugin instance can only be deleted after the *DomainParticipant* with which it was registered is deleted. Note that a transport plugin cannot be "unregistered" from a *DomainParticipant*.

A transport plugin instance cannot be registered with more than one *DomainParticipant* at a time. This requirement is necessary to guarantee the multi-threaded safety of the transport API.

Thus, if the same physical transport resources are to be used with multiple *DomainParticipants* in the same address space, the transport plugin should be written in such a way so that it can be instantiated multiple times—once for each *DomainParticipant* in the address space. Note that it is always possible to write the transport plugin so that multiple transport plugin instances share the same underlying resources; however the burden (if any) of guaranteeing multi-threaded safety to access shared resource shifts to the transport plugin developer.

## 51.7.2 Transport Aliases

In order to use a transport plugin instance in a *Connex*t application, it must be registered with a *DomainParticipant* using the **register\_transport()** operation ([51.7 Installing Additional Builtin Transport Plugins with register\\_transport\(\) on page 979](#)). **register\_transport()** takes a pointer to the transport plugin instance, and in addition allows you to specify a sequence of "alias" strings to symbolically refer to the transport plugin. The same alias strings can be used to register more than one transport plugin.

Multiple transport plugins can be registered with a *DomainParticipant*. An alias symbolically refers to one or more transport plugins registered with the *DomainParticipant*. Pre-configured builtin transport plugin instances can be referred to using preconfigured aliases.

A transport plugin's class name is automatically used as an implicit alias. It can be used to refer to all the transport plugin instance of that class.

You can use aliases to refer to transport plugins in order to specify:

- Transport plugins to use for discovery (see **enabled\_transports** in [44.2 DISCOVERY QoS Policy \(DDS Extension\) on page 699](#)), and for *DataWriters* and *DataReaders* (see [47.27 TRANSPORT\\_SELECTION QoS Policy \(DDS Extension\) on page 858](#)).
- Multicast addresses on which to receive discovery messages (see **multicast\_receive\_addresses** in [44.2 DISCOVERY QoS Policy \(DDS Extension\) on page 699](#)), and the multicast addresses and ports on which to receive user data (`DDS_DataReaderQos::multicast`).
- Unicast ports used for user data (see [47.28 TRANSPORT\\_UNICAST QoS Policy \(DDS Extension\) on page 859](#)) on both *DataWriters* and *DataReaders*.
- Transport plugins used to parse an address string in a locator.

A *DomainParticipant* (and its contained entities) will start using a transport plugin after the *DomainParticipant* is enabled (see [15.2 Enabling DDS Entities on page 35](#)). An entity will use all the transport plugins that match the specified transport QoS policy. All transport plugins are treated uniformly, regardless of how they were created or registered; there is no notion of some transports being more "special" than others.

## 51.7.3 Transport Network Addresses

The address bits *not* used by the transport plugin for its internal addressing constitute its network address bits.

In order for *Connex*t to properly route the messages, each unicast interface in the DDS domain must have a unique address.

You specify the network address when installing a transport plugin via the **register\_transport()** operation ([51.7 Installing Additional Builtin Transport Plugins with register\\_transport\(\) on page 979](#)). Choose the network address for a transport plugin so that the resulting fully qualified 128-bit address will be unique in the DDS domain.

If two instances of a transport plugin are registered with a *DomainParticipant*, they need different network addresses so that their unicast interfaces will have unique, fully qualified 128-bit addresses.

While it is possible to create multiple transports with the same network address (this can be useful for certain situations), this requires special entity configuration for most transports to avoid clashes in resource use (e.g., sockets for UDPv4 transport).

## 51.8 Installing Additional Builtin Transport Plugins with PropertyQosPolicy

Similar to default builtin transport instances, additional builtin transport instances can also be configured through [47.19 PROPERTY QosPolicy \(DDS Extension\) on page 837](#).

To install additional instances of builtin transport, the Properties listed in [Table 51.6 Properties for Dynamically Loading and Registering Additional Builtin Transport Plugins](#) are required.

**Table 51.6 Properties for Dynamically Loading and Registering Additional Builtin Transport Plugins**

Property Name	Description
dds.transport.load_plugins	Comma-separated list of <TRANSPORT_PREFIX>. Up to 8 entries may be specified.
<TRANSPORT_PREFIX>	<p>Indicates the additional builtin transport instances to be installed, and must be in one of the following form, where &lt;STRING&gt; can be any string other than "builtin":</p> <p>dds.transport.shmem.&lt;STRING&gt;</p> <p>dds.transport.UDPv4.&lt;STRING&gt;</p> <p>dds.transport.UDPv6.&lt;STRING&gt;</p> <p>In the following examples in this table, &lt;TRANSPORT_PREFIX&gt; is used to indicate one element of this string that is used as a prefix in the property names for all the settings that are related to the plugin.</p>

**Table 51.6 Properties for Dynamically Loading and Registering Additional Builtin Transport Plugins**

Property Name	Description
<TRANSPORT_PREFIX>. aliases	Optional. Aliases used to register the transport to the <i>DomainParticipant</i> . Refer to the <b>aliases_in</b> parameter in <b>register_transport()</b> (see <a href="#">51.7 Installing Additional Builtin Transport Plugins with register_transport()</a> on page 979). Aliases should be specified as a comma separated string, with each comma delimiting an alias.  If it is not specified, the prefix—without the leading " <b>dds.transport</b> "—is used as the default alias for the plugin. For example, if the <TRANSPORT_PREFIX> is " <b>dds.transport.mytransport</b> ", the default alias for the plugin is " <b>mytransport</b> ".
<TRANSPORT_PREFIX>. network_address	Optional. Network address used to register the transport to the <i>DomainParticipant</i> . Refer to <b>network_address_in</b> parameter in <b>register_transport()</b> (see <a href="#">51.7 Installing Additional Builtin Transport Plugins with register_transport()</a> on page 979). If it is not specified, the <b>network_address_out</b> output parameter from <b>NDDS_Transport_create_plugin</b> is used. The default value is a zeroed out network address.
<TRANSPORT_PREFIX>. <property_name>	Optional. Property for creating the transport plugin. More than one <TRANSPORT_PREFIX>.<property_name> can be specified. See <a href="#">Table 51.2 Properties for the Builtin UDPv4 Transport</a> through <a href="#">Table 51.4 Properties for Builtin Shared-Memory Transport</a> for the property names that can be used to configure the additional builtin transport instances. The only difference is that the property name will be prefixed by <b>dds.transport.&lt;builtin_transport_name&gt;.&lt;instance_name&gt;</b> , where <instance_name> is configured through the <b>dds.transport.load_plugins</b> property instead of <b>dds.transport.&lt;builtin_transport_name&gt;.builtin</b> .

## 51.9 Other Transport Support Operations

### 51.9.1 Adding a Send Route

By default, a transport plugin will send outgoing messages using the network address range at which the plugin was registered.

The **add\_send\_route()** operation allows you to control the routing of outgoing messages, so that a transport plugin will only send messages to certain ranges of destination addresses.

Before using this operation, the *DomainParticipant* to which the transport is registered must be disabled.

```
DDS_ReturnCode_t NDDSTransportSupport::add_send_route (
    const NDDS_Transport_Handle_t & transport_handle_in,
    const NDDS_Transport_Address_t & address_range_in,
    DDS_Long address_range_bit_count_in)
```

Where:

- transport\_handle\_in** A valid non-NIL transport handle as a result of a call to **register\_transport()** ([51.7 Installing Additional Builtin Transport Plugins with register\\_transport\(\)](#) on page 979).
- address\_range\_in** The outgoing address range for which to use this transport plugin.
- address\_range\_bit\_count\_in** The number of most significant bits used to specify the address range.

It returns one of the standard return codes or **DDS\_RETCODE\_PRECONDITION\_NOT\_MET**.

The method can be called multiple times for a transport plugin, with different address ranges. You can set up a routing table to restrict the use of a transport plugin to send messages to selected addresses ranges.

Outgoing Address Range 1	->	Transport Plugin
...	->	...
Outgoing Address Range K	->	Transport Plugin

## 51.9.2 Adding a Receive Route

By default, a transport plugin will receive incoming messages using the network address range at which the plugin was registered.

The **add\_receive\_route()** operation allows you to configure a transport plugin so that it will only receive messages on certain ranges of addresses.

Before using this operation, the *DomainParticipant* to which the transport is registered must be disabled.

```
DDS_ReturnCode_t NDDSTransportSupport::add_receive_route(
    const NDDS_Transport_Handle_t & transport_handle_in,
    const NDDS_Transport_Address_t & address_range_in,
    DDS_Long address_range_bit_count_in)
```

Where:

- transport\_handle\_in**      A valid non-NIL transport handle as a result of a call to **register\_transport()** (51.7 Installing Additional Builtin Transport Plugins with register\_transport() on page 979).
- address\_range\_in**      The incoming address range for which to use this transport plugin.
- address\_range\_bit\_count\_in**      The number of most significant bits used to specify the address range.

It returns one of the standard return codes or `DDS_RETCODE_PRECONDITION_NOT_MET`.

The method can be called multiple times for a transport plugin, with different address ranges.

Transport Plugin	<-	Incoming Address Range 1
...	<-	...
Transport Plugin	<-	Incoming Address Range M

You can set up a routing table to restrict the use of a transport plugin to receive messages from selected ranges. For example, you may restrict a transport plugin to:

Receive messages from a certain multicast address range.

Receive messages only on certain unicast interfaces (when multiple unicast interfaces are available on the transport plugin).

### 51.9.3 Looking Up a Transport Plugin

If you need to get the handle associated with a transport plugin that is registered with a *DomainParticipant*, use the **lookup\_transport()** operation.

```
NDDS_Transport_Handle_t NDDSTransportSupport::lookup_transport (
    DDSDomainParticipant * participant_in,
    DDS_StringSeq & aliases_out,
    NDDS_Transport_Address_t & network_address_out,
    NDDS_Transport_Plugin * transport_in )
```

Where:

<b>participant_in</b>	A non-NULL <i>DomainParticipant</i> .
<b>aliases_out</b>	A sequence of strings where the aliases used to refer to the transport plugin symbolically will be returned. NULL if not interested.
<b>network_address_out</b>	The network address at which to register the transport plugin will be returned here. NULL if not interested.
<b>transport_in</b>	A non-NULL transport plugin that is already registered with the <i>DomainParticipant</i> .

If successful, this operation returns a valid non-NIL transport handle, representing the association between the *DomainParticipant* and the transport plugin; otherwise it returns a `NDDS_TRANSPORT_HANDLE_NIL` upon failure.

# Chapter 52 RTI Real-Time WAN Transport

*Real-Time WAN Transport* is a *Connex*t transport plugin that enables communication over wide area networks (WANs) using UDP as the underlying IP transport-layer protocol.

The material in this part of the manual is only relevant if you have installed *Real-Time WAN Transport*. This feature is not installed as part of a *Connex*t package; it must be downloaded and installed separately. See the [RTI Real-Time WAN Transport Installation Guide](#) for details. See also the [RTI Real-Time WAN Transport Release Notes](#).

This section includes:

## 52.1 Introduction to Real-Time WAN Transport

*Real-Time WAN Transport* is a smart transport that enables secure, scalable, and high-performance communication over wide area networks (WANs), including public networks. It extends *Connex*t capabilities to WAN environments. *Real-Time WAN Transport* uses UDP as the underlying IP transport-layer protocol to better anticipate and adapt to the challenges of diverse network conditions, device mobility, and the dynamic nature of WAN system architectures.

*Real-Time WAN Transport*, in combination with *RTI Cloud Discovery Service*, provides a complete, seamless solution out of the box for WAN connectivity. This WAN connectivity solution, including *Real-Time WAN Transport* and *Cloud Discovery Service*, is available as an optional add-on.

*Real-Time WAN Transport* replaces the transport capabilities of the *Secure WAN Transport* optionally available with previous *Connex*t releases, and provides the following capabilities:

- **NAT (Network Address Translator) traversal:** Ability to communicate between *DomainParticipants* running in a Local Area Network (LAN) that is behind a NAT-enabled router, and *DomainParticipants* on the outside of the NAT across a WAN. This functionality is provided in combination with *Cloud Discovery Service* (see [52.3.1 NAT Traversal on the next page](#)).
- **IP mobility:** Support for network transitions and changes in IP addresses in any of the *DomainParticipants* participating in the communication (see [52.3.7 IP Mobility on page 994](#)).
- **Security:** Secure communications between *DomainParticipants* using *Security Plugins* (see [52.9 Security on page 1032](#)).

*Real-Time WAN Transport* does not require third-party components, such as STUN servers, or protocols like SIP to handle session establishment. Using a single API and security model, you can leverage the extensive capabilities of the *Connex* framework and ecosystem, including tools and infrastructure services, even for real-time connectivity from edge to cloud and back in highly distributed systems that communicate across wide area networks.

For *Real-Time WAN Transport* example code, see [https://github.com/rticommunity/rticonnextdds-examples/tree/develop/examples/connex\\_dds/real\\_time\\_wan\\_transport](https://github.com/rticommunity/rticonnextdds-examples/tree/develop/examples/connex_dds/real_time_wan_transport).

## 52.2 Key Terms

### 52.2.1 Basic Terms

**Wide Area Network (WAN):** A wide area network (WAN) is a collection of local area networks (LANs) or other networks that communicate with one another. A WAN is essentially a network of networks, with the Internet being the world's largest WAN.

**Cellular Network (or Cellular WAN):** A cellular network is a wide area network for voice and data that is typically provided by the cellular carriers to transmit a wireless signal over a range of several miles to a mobile device.

**External DomainParticipant:** A *DomainParticipant* using a *Real-Time WAN Transport* that is publicly reachable at a public address. Being reachable at a public IP address does not mean that the *DomainParticipant* is not behind a NAT-enabled router. It is possible that an external *DomainParticipant* is behind a NAT-enabled router if the network administrator configures a static NAT mapping between the *DomainParticipant* private address and a public address.

### 52.2.2 IP Address Types

**IP Transport Address (or Address):** The combination of the IPv4 address and the UDP Port where an application accepts incoming traffic. Sometimes you will also see the term "address" being used to refer to an IP transport address when the context is clear.

**External IP Transport Address (or External Address or Public Address):** An IP transport address that is routable on a WAN. When the WAN is the Internet, the term "Internet-routable address" can be used instead.

**Private IP Transport Address (or Private Address or Internal Address):** The IP transport address of an application that sits behind a NAT. This address is not reachable from external applications running outside the NAT.

**Service Reflexive Address:** The public IP transport address that *Cloud Discovery Service* obtains for a UUID locator contained in the participant announcement sent by a *DomainParticipant*.

### 52.2.3 Locators

**RTPS Locator (or Locator):** A *Connex* endpoint (*DataWriter* or *DataReader*) address unit that consists of a transport class, RTPS port, and locator transport address (128-bit).

**Reachable Locator:** Locator associated with a DDS endpoint (*DataWriter* or *DataReader*) to which another DDS endpoint can send data.

**RTPS UUID WAN Locator (or UUID Locator):** A WAN locator for a *Real-Time WAN Transport* that is not reachable. UUID locators are transformed into UUID+PUBLIC locators by associating a public IP transport address to the UUID.

**RTPS UUID+PUBLIC WAN Locator (or UUID+PUBLIC Locator):** A WAN locator for a *Real-Time WAN Transport* that is reachable. The locator encapsulates a public IP transport address as part of the locator address.

### 52.2.4 WAN Ecosystem

**Session Traversal Utilities for NAT (STUN):** Standardized set of methods, including a network protocol, for traversal of network address translator gateways in applications of real-time voice, video, messaging, and other interactive communications.

**STUN Server:** A STUN server enables clients to find out their public IP transport address and NAT type.

**Interactive Connectivity Establishment (ICE):** ICE is a protocol used for NAT traversal. ICE uses a combination of methods including STUN and Traversal Using Relay NAT (TURN) to traverse NATs.

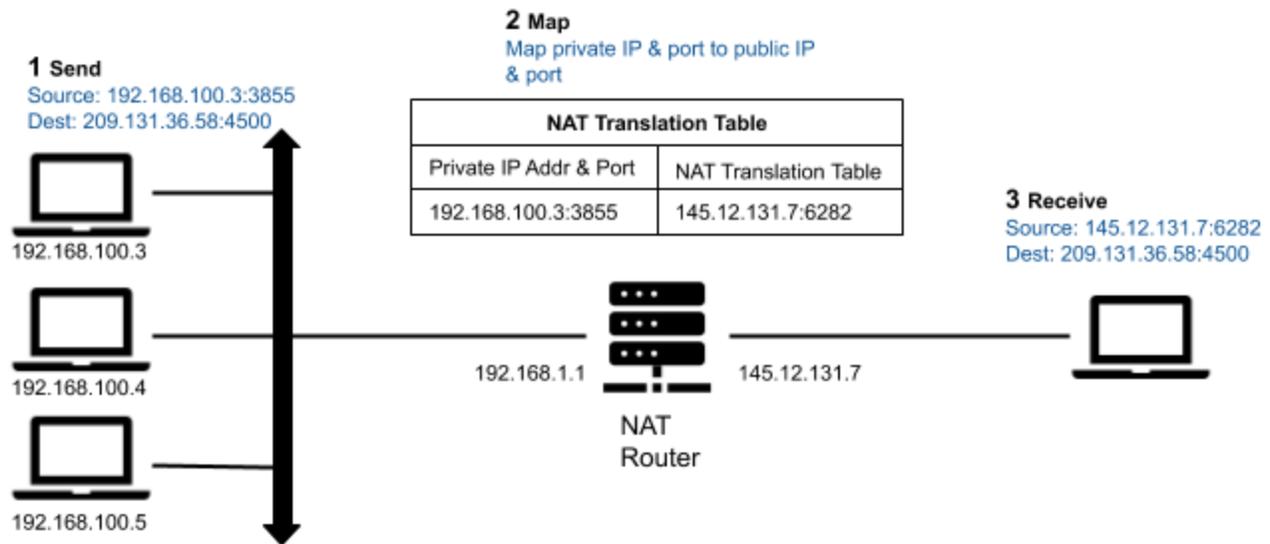

## 52.3 Transport Capabilities

### 52.3.1 NAT Traversal

In WAN environments, applications running behind a NAT-enabled router typically need to communicate with applications running behind a different NAT-enabled router. NAT (Network Address Translation) is a method of remapping one private IP address and port into a public IP address and port

by modifying the IP address and port information in the IP header of the packets while they are in transit across a NAT-enabled router. The technique has become a popular and essential tool in conserving the IPv4 global address space in the face of IPv4 address exhaustion. Many applications with individual private IP addresses can utilize a NAT-enabled router to communicate with external applications using a single public IP address.

Figure 52.1: NAT Traversal

*Real-Time WAN Transport* in combination with *Cloud Discovery Service* will enable communications between *Connex* applications running between different kinds of NATs. For information on the various NAT kinds, please see the following sections.

## 52.3.2 NAT Kinds

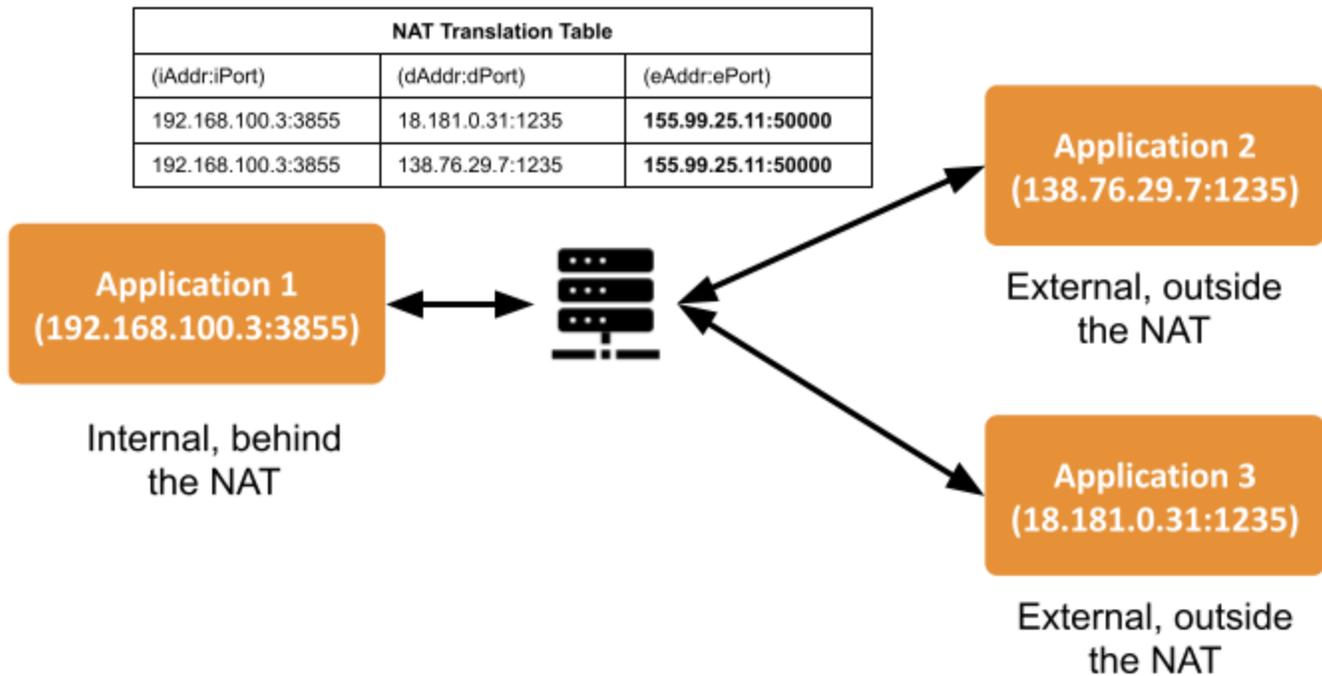

There are four kinds of NATs:

### 52.3.2.1 Full-Cone NAT (or One-to-One NAT)

A full-cone NAT, also known as a one-to-one NAT, has the following characteristics:

- Once an internal address (iAddr:iPort) is mapped to an external address (eAddr:ePort) by the NAT router, any packets from (iAddr:iPort) are sent through (eAddr:ePort).
- Any external host can send packets to (iAddr:iPort) by sending packets to (eAddr:ePort), regardless of the external host address/port (dAddr:dPort) used to send the packets.

Figure 52.2: Full-Cone NAT

### 52.3.2.2 Address-Restricted-Cone NAT

- Once an internal address (iAddr:iPort) is mapped to an external address (eAddr:ePort) by the NAT router, any packets from (iAddr:iPort) are sent through eAddr:ePort.
- An external host (dAddr:any) can send packets to (iAddr:iPort) by sending packets to (eAddr:ePort) only if (iAddr:iPort) has previously sent a packet to (dAddr:any). "Any" means the port number doesn't matter.

### 52.3.2.3 Port-Restricted Cone NAT

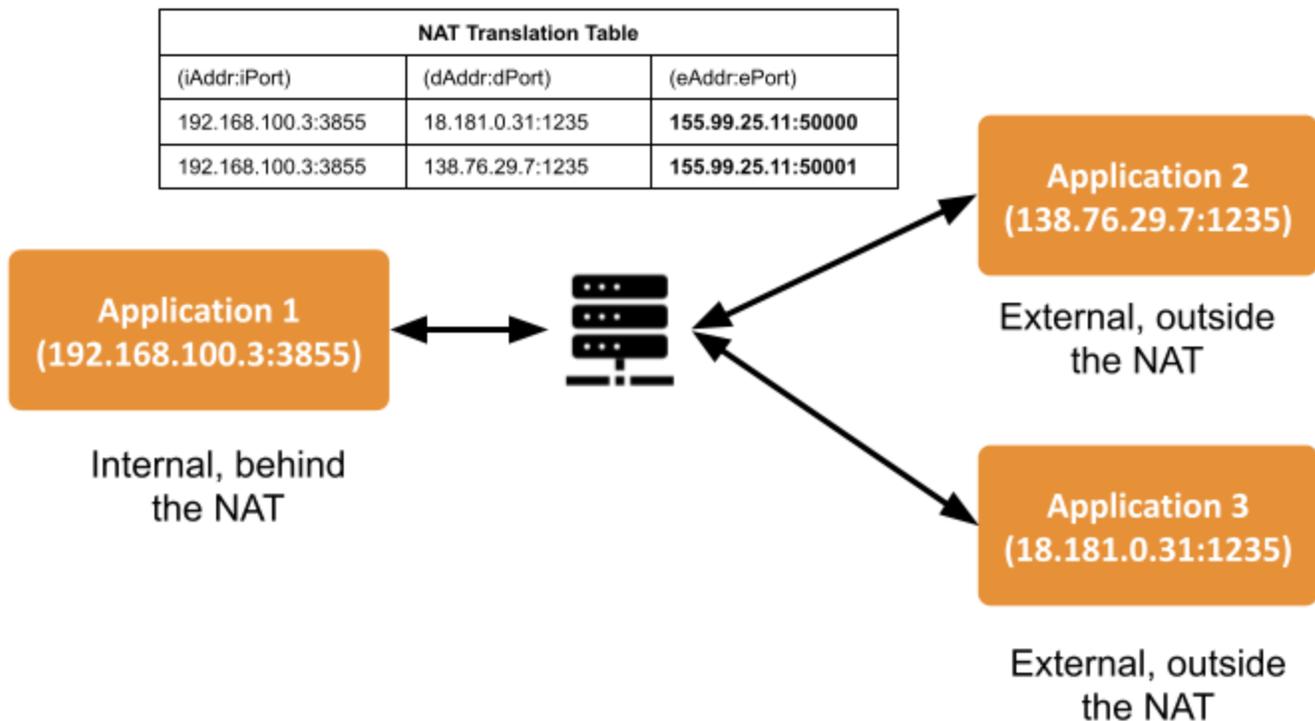

This NAT is similar to an address-restricted cone NAT, but the restriction also includes port numbers.

- Once an internal address (iAddr:iPort) is mapped to an external address (eAddr:ePort) by the NAT router, any packets from (iAddr:iPort) are sent through (eAddr:ePort).
- An external host (dAddr:dPort) can send packets to (iAddr:iPort) by sending packets to (eAddr:ePort) only if (iAddr:iPort) has previously sent a packet to (dAddr:dPort).

### 52.3.2.4 Symmetric NAT

- Each request from the same internal IP address and port (iAddr:iPort) to a specific destination IP address and port (dAddr:dPort) is mapped by the NAT router to a unique external source IP address and port (eAddr:ePort). If the same internal host sends a packet even with the same source address and port but to a different destination, a different mapping is used.
- Only an external host that receives a packet from an internal host can send a packet back.

Figure 52.3: Symmetric NAT

### 52.3.3 Identifying the NAT Type

There are multiple third-party utilities that you can download to find out the NAT type. One example is *natat* (<https://github.com/songjiayang/natat>).

```

> ./natat
2020/11/21 11:10:52 start stun server ping...
2020/11/21 11:10:53 stun.1.google.com:19302 mapped: 0.0.0.0:3489 -> 99.35.17.233:3489
2020/11/21 11:10:53 stun1.1.google.com:19302 mapped: 0.0.0.0:3489 -> 99.35.17.233:3489
2020/11/21 11:10:53 start NAT type assert...
2020/11/21 11:10:53 It's Cone NAT

```

## 52.3.4 NAT Bindings

Applications behind a NAT cannot receive data from applications outside the NAT unless they open a UDP NAT binding (or UDP hole) with each one of the public IP transport addresses associated with the applications running outside the NAT.

A NAT binding creates a mapping between a private IP transport address (iAddr:iPort) and a public IP transport address (eAddr:ePort) for a given set of destination IP transport addresses. There are two kinds of bindings:

- **Static bindings (also known as port forwarding):** You can set the configuration of a NAT-enabled router to map (iAddr:iPort) to (eAddr:ePort) (see [Figure 52.4: Open a Static Binding in a NAT-Enabled Router on the next page](#)) for all destination addresses. These bindings allow incoming traffic from any external IP transport address.
- **Dynamic bindings:** The bindings are opened dynamically when the application running inside the NAT sends a message to a destination IP transport address outside the NAT. The behavior of the dynamic bindings depends on the type of NAT (see [52.3.2 NAT Kinds on page 989](#)). Unlike static bindings, dynamic bindings can expire if there is no outgoing traffic (see [52.3.5 NAT Bindings Expiration on the next page](#)).

Figure 52.4: Open a Static Binding in a NAT-Enabled Router

System Info Broadband LAN **Firewall** Logs Diagnostics

Status Applications, Pinholes and DMZ Advanced Configuration Firewall Rules Parental Control

### Firewall Application Profile Definition

If the desired application requires multiple ports of both TCP and UDP ports, you will need to add multiple definitions. Current definitions for this profile are shown in the Definition List below.

Application Profile Name

#### Create Application Definition

Protocol  TCP  UDP

Port (or Range) From  To

Protocol Timeout  TCP default 86400 seconds, UDP default 600 seconds

Map to Host Port  Default/blank = same port as above

Application Type

Note: In some rare instances, certain application types require specialized firewall changes in addition to simple port forwarding. If the application you are adding appears in the application type menu above, it is recommended that you select it.

#### Definition List

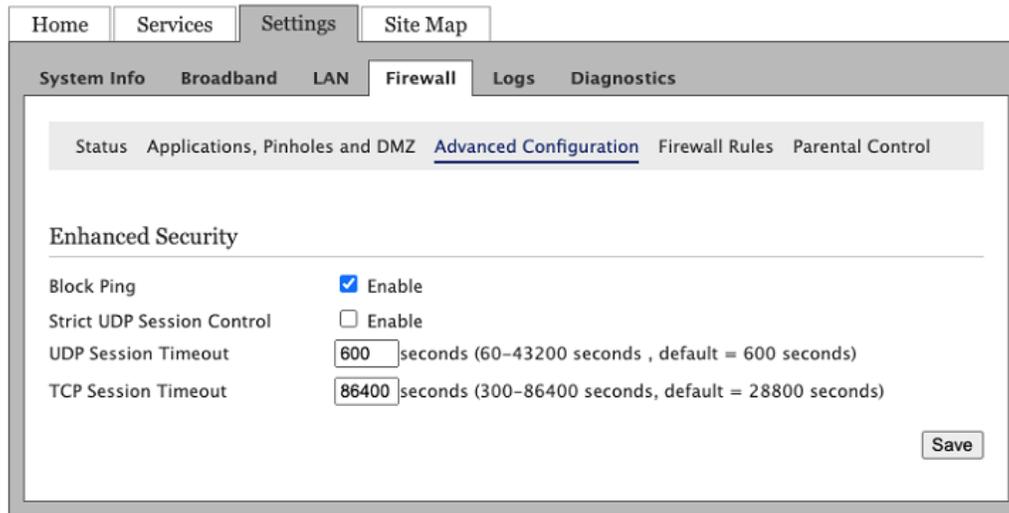

No Available Definition

## 52.3.5 NAT Bindings Expiration

*Real-Time WAN Transport* will be able to establish new NAT bindings if the old bindings are closed by the NAT-enabled router without any user intervention. In addition, *Real-Time WAN Transport* provides a builtin **Ping** mechanism to keep the NAT bindings open at all times. This capability eliminates the latency penalty that is introduced during the process of establishing a new NAT binding.

For security purposes, in the absence of outbound traffic, the NAT binding from an internal address (iAddr:iPort) to an external address (eAddr:ePort) usually expires after periods of time in the range of tens of seconds to a few minutes. When it expires, the NAT binding is removed and it closes. The expiration time can usually be configured (see [Figure 52.5: Session Timeout on the next page](#)).

Figure 52.5: Session Timeout

## 52.3.6 NAT Hairpinning

*Real-Time WAN Transport* does not require support for NAT hairpinning and can be used in combination with the builtin UDPv4 transport in a *DomainParticipant* to support both communication with *DomainParticipants* within the same LAN and communication with *DomainParticipants* in a WAN simultaneously.

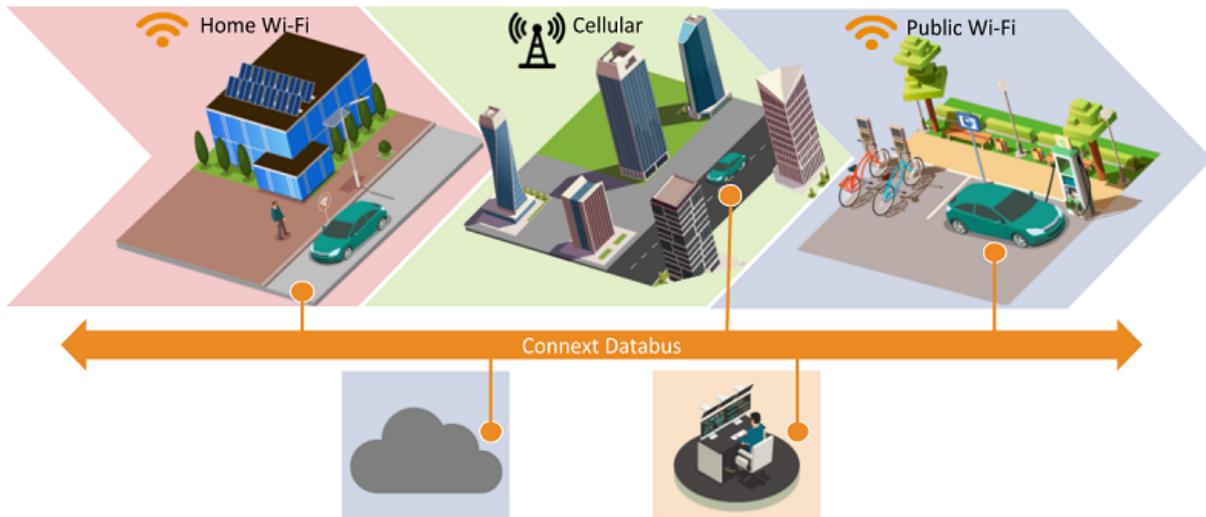

In network computing, hairpinning (or NAT loopback) refers to communication between two hosts behind the same NAT router using their mapped external address (eAddr:ePort). Because not all NAT routers support this communication configuration, usually applications must be designed to be aware of it.

## 52.3.7 IP Mobility

*Real-Time WAN Transport* automatically and transparently handles the IP address changes in the applications communicating over the WAN, without any application intervention.

In WAN communication scenarios, it is common for applications to roam among different networks, changing their IP addresses. For example, assume the following scenario:

Figure 52.6: Network Transition

*Connectivity continues with the vehicle while it transitions between different networks as it drives from one point to another in the city*

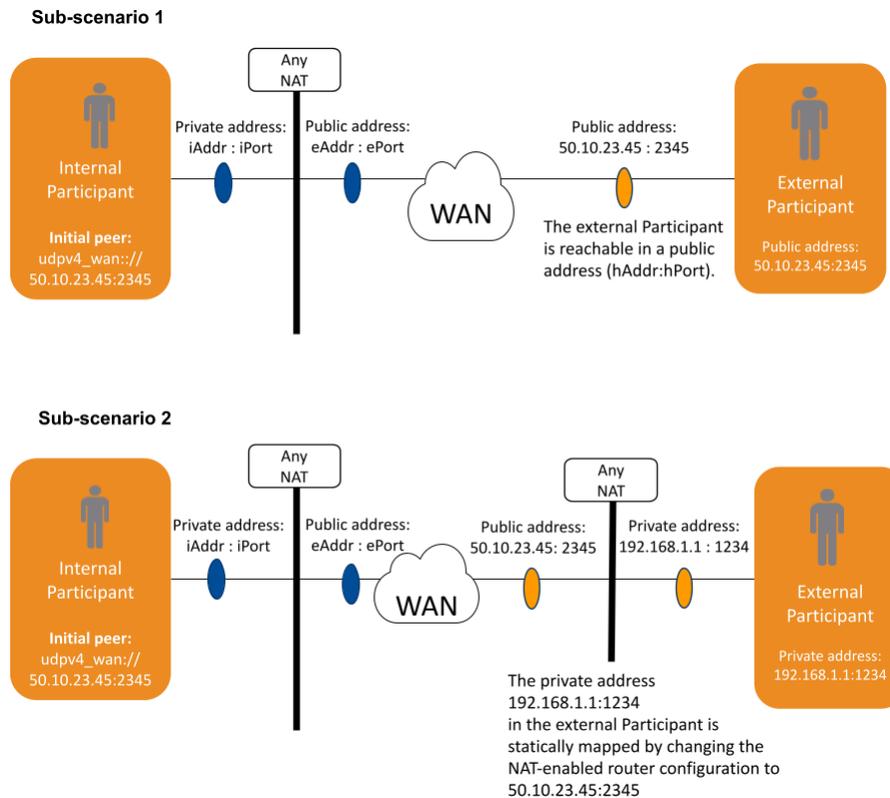

## 52.4 Communication Scenarios

*Real-Time WAN Transport* can be used to address two basic communication scenarios between *Connex DomainParticipants*.

### 52.4.1 Peer-to-Peer Communication between Internal Participant and External Participant

In this scenario, one or more *DomainParticipants* behind any kind of NAT (including symmetric NATs) communicate with a *DomainParticipant* with a well-known public IP transport address (see [Figure 52.7: Peer-to-Peer between a Participant behind Any Kind of NAT and an External Participant on the next page](#)).

Figure 52.7: Peer-to-Peer between a Participant behind Any Kind of NAT and an External Participant

Note that *Cloud Discovery Service (CDS)* is not needed to facilitate NAT traversal in this scenario because the external *DomainParticipant* can figure out the public IP transport addresses at which the Internal Participant is reachable by looking at the UDP packets coming from the Internal Participant.

The external *DomainParticipant* must be reachable at a well-known public address (50.10.23.45:2345 in this example). What this means is that the address must be routable on the WAN.

There are two configurations that allow the association of External Participant with a well-known public address:

- **Sub-Scenario 1:** The *DomainParticipant* is associated directly with the public address 50.10.23.45:2345, or
- **Sub-Scenario 2:** The *DomainParticipant* is behind a NAT-enabled router in which you have created a static NAT mapping from the *DomainParticipant* private IP transport address 192.168.1.1:1234 to the public IP transport address 50.10.23.45:2345.

For a detailed description of how the communication establishment protocol works in this scenario, see [52.10.4 Communication Establishment Protocol for Peer-to-Peer Communication with a Participant that has a Public Address](#) on page 1037.

The following section provides an example configuration for the scenario described in [Figure 52.7: Peer-to-Peer between a Participant behind Any Kind of NAT and an External Participant](#) on the previous page.

### 52.4.1.1 External Participant Configuration: Sub-Scenario 1

```
<dds>
  <qos_profile name="ExternalParticipant">
    <domain_participant_qos>
      <transport_builtin>
        <mask>UDPv4_WAN</mask>
        <udpv4_wan>
          <public_address>50.10.23.45</public_address>
          <comm_ports>
            <default>
              <host>2345</host>
            </default>
          </comm_ports>
        </udpv4_wan>
      </transport_builtin>
    </domain_participant_qos>
  </qos_profile>
</dds>
```

- To enable *Real-Time WAN Transport*, <mask> within <transport\_builtin> must contain UDPv4\_WAN.
- <public\_address> contains the IP address of the host where the external *DomainParticipant* is running.
- <comm\_ports> defines the port (<host>) in which the external *DomainParticipant* receives/sends data.

### 52.4.1.2 External Participant Configuration: Sub-Scenario 2

```
<dds>
  <qos_profile name="ExternalParticipant">
    <domain_participant_qos>
      <transport_builtin>
        <mask>UDPv4_WAN</mask>
        <udpv4_wan>
          <public_address>50.10.23.45</public_address>
          <comm_ports>
            <default>
              <host>1234</host>
              <public>2345</public>
            </default>
          </comm_ports>
        </udpv4_wan>
      </transport_builtin>
    </domain_participant_qos>
  </qos_profile>
</dds>
```

```

        </udpv4_wan>
    </transport_builtin>
</domain_participant_qos>
</qos_profile>
</dds>

```

- To enable *Real-Time WAN Transport*, <mask> within <transport\_builtin> must contain UDPv4\_WAN.
- <public\_address> contains the public IP address in the NAT-enabled router to which the private IP address is mapped.
- <comm\_ports> defines the mapping between the following ports:
  - <host>: local UDP port in which the external *DomainParticipant* receives/sends data in the machine where it is running.
  - <public>: public port to which the local UDP port is mapped in the NAT-enabled router.

### 52.4.1.3 Internal Participants Configuration

```

<dds>
  <qos_profile name="InternalParticipant">
    <domain_participant_qos>
      <transport_builtin>
        <mask>UDPv4_WAN</mask>
      </transport_builtin>
      <discovery>
        <initial_peers>
          <element>0@udpv4_wan://50.10.23.45:2345</element>
        </initial_peers>
      </discovery>
    </domain_participant_qos>
  </qos_profile>
</dds>

```

- To enable *Real-Time WAN Transport*, <mask> within <transport\_builtin> must contain UDPv4\_WAN.
- In addition, the InternalParticipant must set its initial peers to point to the external *DomainParticipant* public address.

## 52.4.2 Peer-to-Peer Communication between Two Internal Participants

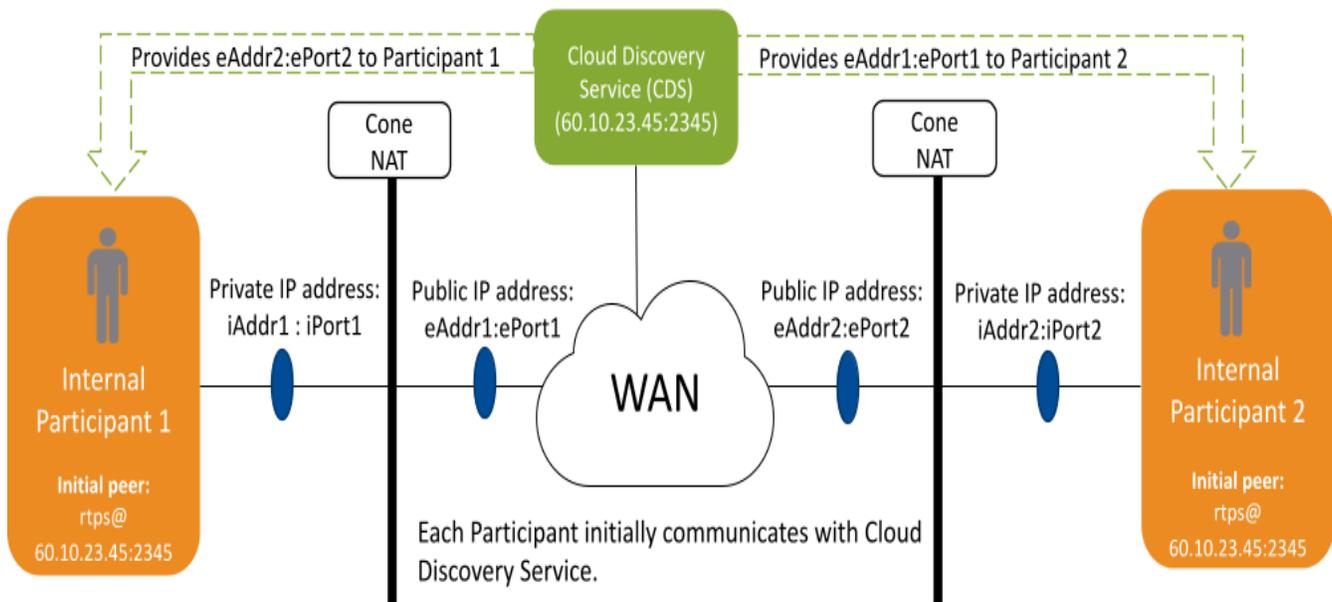

In this communication scenario, the two *DomainParticipants* trying to communicate with each other are internal participants; therefore, they are not reachable at a well-known public address.

This scenario requires *Cloud Discovery Service* (CDS) to map the private addresses of the *DomainParticipants* into public addresses (called service reflexive addresses) and provide these public addresses to other *DomainParticipants* so that they can start communicating peer-to-peer.

This scenario requires that the *DomainParticipants* communicating over a WAN are behind cone NATs (see [Figure 52.8: Peer-to-Peer between Participants behind Cone NATs](#) below), or that one of the *DomainParticipants* is behind a full-cone NAT and the other is behind any kind of NAT.

To verify the type of NAT the applications run, see [52.3.3 Identifying the NAT Type on page 991](#).

**Figure 52.8: Peer-to-Peer between Participants behind Cone NATs**

Cloud Discovery Service also serves as a directory, so that a participant only needs to know about the CDS public address to connect to multiple peers automatically.

The service reflexive addresses obtained by CDS are provided as part of the WAN locators contained in the participant announcement sent from CDS to the application *DomainParticipants*.

In [Figure 52.8: Peer-to-Peer between Participants behind Cone NATs](#) above, eAddr2:ePort2 is the service reflexive address that CDS obtains for Internal Participant 2, and eAddr1:ePort1 is the service reflexive address that CDS obtains for Internal Participant 1. CDS provides eAddr2:ePort2 to Internal Participant 1 so that it can reach Internal Participant 2; it provides eAddr1:ePort1 to Internal Participant 2 so that it can reach Internal Participant 1.

For a detailed description of how the communication establishment protocol works when the *DomainParticipants* are behind cone NATs, see [52.10.3 Communication Establishment Protocol for Peer-to-Peer Communication with Participants behind Cone NATs on page 1034](#).

The following section provides an example configuration for the scenario described in [Figure 52.8: Peer-to-Peer between Participants behind Cone NATs](#) above.

### 52.4.2.1 Internal and External Participants Configuration

```
<dds>
  <qos_profile name="InternalParticipant">
    <domain_participant_qos>
      <transport_builtin>
        <mask>UDpv4_WAN</mask>
      </transport_builtin>
      <discovery>
        <initial_peers>
          <element>rtps@udpv4_wan://60.10.23.45:2345</element>
        </initial_peers>
      </discovery>
    </domain_participant_qos>
  </qos_profile>
</dds>
```

- To enable the *Real-Time WAN Transport*, specify the transport in `<transport_builtin>/<mask>` as `UDpv4_WAN`.
- When you specify the initial peers of the `InternalParticipant` in `<initial_peers>/<element>`, use the public address of the *Cloud Discovery Service*.

### 52.4.2.2 Cloud Discovery Service Configuration

```
<dds>
  <cloud_discovery_service name="CDS">
    <transport>
      <element>
        <alias>builtin.udpv4_wan</alias>
        <receive_port>2345</receive_port>
        <property>
          <element>
            <name>dds.transport.UDpv4_WAN.builtin.public_address</name>
            <value>60.10.23.45</value>
          </element>
        </property>
      </element>
    </transport>
  </cloud_discovery_service>
</dds>
```

- To enable *Real-Time WAN Transport* in CDS, set `<alias>` to `builtin.udpv4_wan`.
- `<receive_port>` contains the public UDP port in which CDS is reachable by the *DomainParticipants*.
- `dds.transport.UDpv4.builtin.public_address` contains the public IP address in which CDS is reachable by the *DomainParticipants*.

For additional details on each one of the parameters of the CDS instance configuration, see the *RTI Cloud Discovery Service* documentation.

As described above, CDS must be reachable in a well-known public address, in this example 60.10.23.45:2345. A "well-known" public address is an address that is routable on the WAN.

There are two configurations that allow the association of CDS with a well-known public address:

1. The CDS network interface card (NIC) is associated directly with the public address.
2. CDS is behind a NAT-enabled router, and you have created a static NAT mapping from the CDS private address `iAddr:iPort` to the public address 60.10.23.45:2345.

If CDS is behind a NAT-enabled router, the host port (iPort) must be the same as the `<receive_port>` (2345). If you want to use a different host port, it will be necessary to configure the property `dds.transport.UDPv4.WAN.builtin.comm_ports` ([52.8.2.1.1 Changing the UDP Port Mapping on page 1025](#)).

## 52.5 Deployment Scenarios

The communication scenarios described in [52.4 Communication Scenarios on page 995](#) provide the building blocks for WAN communication using *Real-Time WAN Transport*. However, they do not take into consideration important communication aspects such as scalability.

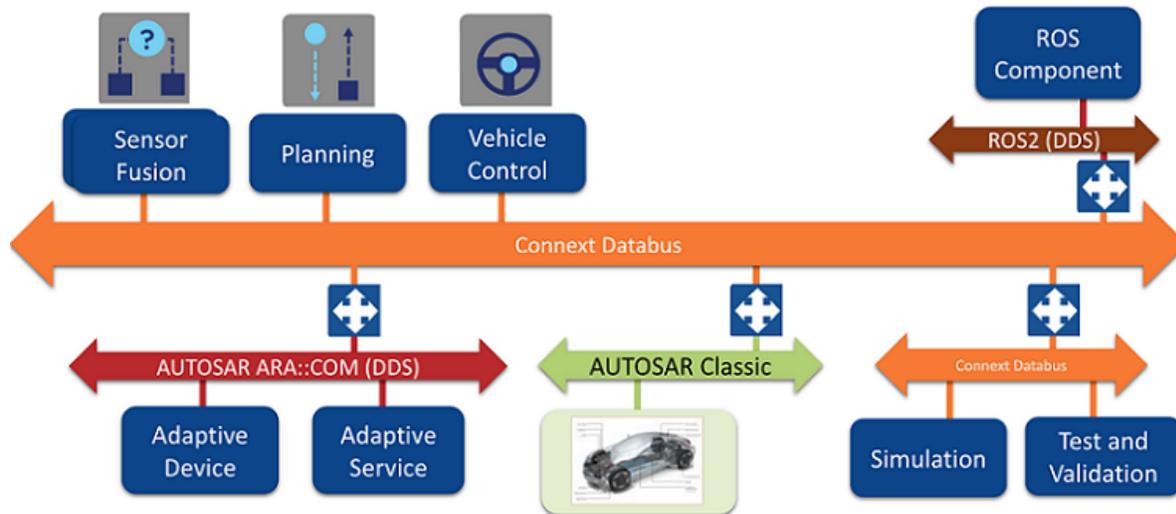

The intent of this section is to describe some of the most common deployment scenarios for *Real-Time WAN Transport*.

### 52.5.1 Edge-to-Data Center Deployment Scenario

In traditional *Connex*t applications, most of the data processing is done on the edge devices. However, as these applications are distributed across the WAN, it becomes necessary to move some computation and storage to data centers or clouds.

Consider the use case of autonomous driving technology. In this scenario, each vehicle has one or more internal *Connex*t databuses in which different applications run to provide capabilities such as sensor fusion, path planning, vehicle control, and so on.

Figure 52.9: In-Vehicle Edge Connex Databus

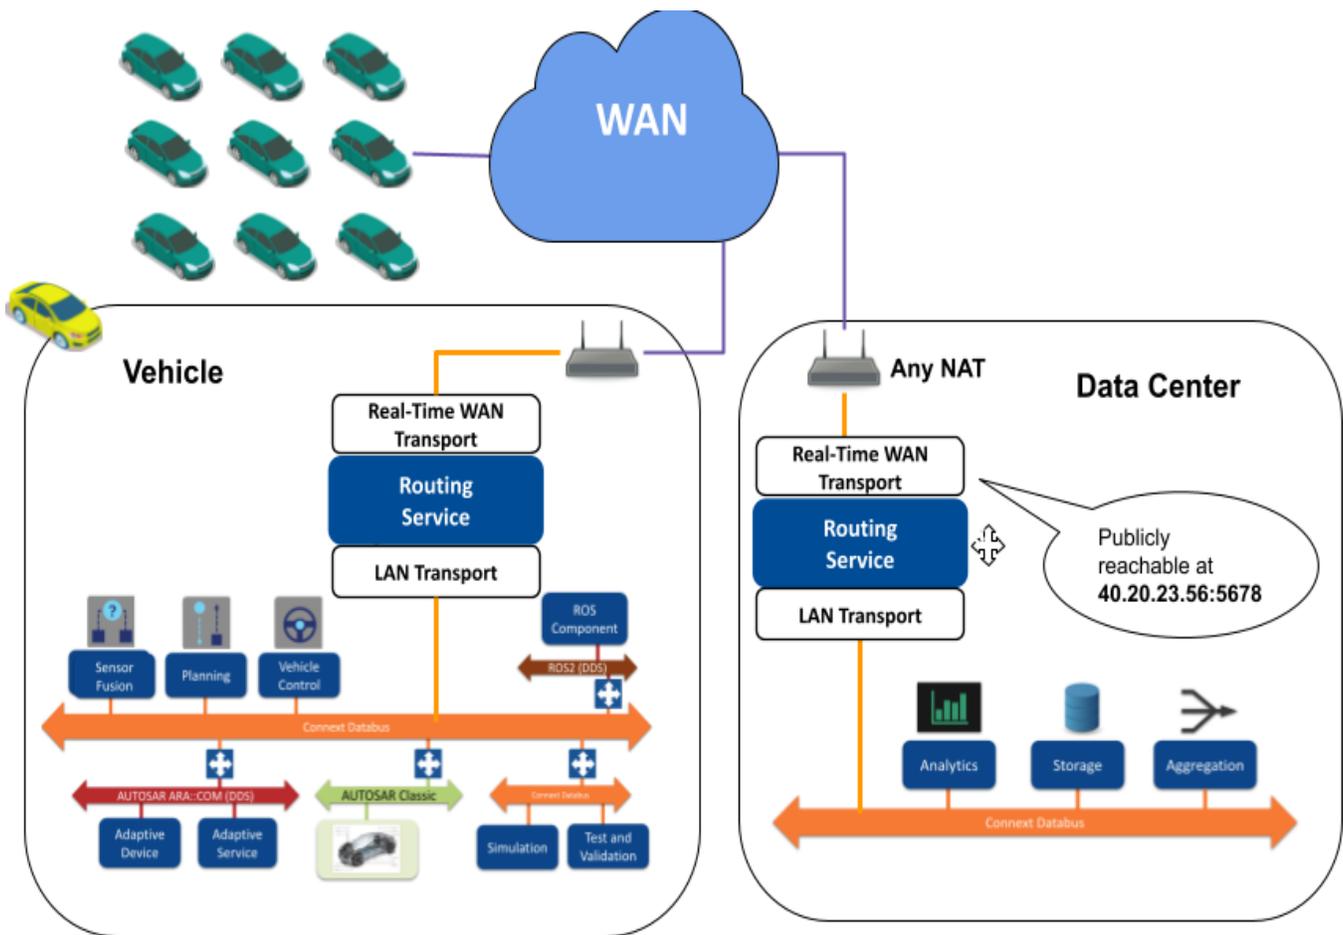

Some of the information generated in the Edge Connex Databus may have to be sent outside the vehicle to different data centers and/or clouds to support use cases such as data storage, data analytics, and others. Likewise, the vehicle may have to receive information from the data centers and/or cloud such as over-the-air (OTA) updates.

Instead of configuring a large number of *DomainParticipants* running inside the vehicle to use *Real-Time WAN Transport*, it is more scalable and secure to provide a gateway component within the vehicle whose main purpose is to send and receive the necessary information from the data centers. This gateway component is provided by *RTI Routing Service*.

There is also a gateway *Routing Service* instance running in the data center in order to send and receive information from the vehicles. That way it is not necessary to configure every *DomainParticipant* running in the data center to use *Real-Time WAN Transport*.

[Figure 52.10: Edge-to-Data Center Communication on the next page](#) shows the deployment scenario for a fleet of vehicles using a *Routing Service* in the vehicles and in the data center.

Figure 52.10: Edge-to-Data Center Communication

The following sections provide an example configuration for the scenario described in [Figure 52.10: Edge-to-Data Center Communication](#) above. The *Routing Service* instances are configured to propagate every *Topic*. However, in a real scenario only a subset of the *Topics* would be propagated.

### 52.5.1.1 Data Center Routing Service Configuration

```
<dds>
  <routing_service name="RS">
    <domain_route name="TwoWayDomainRoute">
      <participant name="0">
        <domain_participant_qos>
          <transport_builtin>
            <mask>UDPv4</mask>
          </transport_builtin>
        </domain_participant_qos>
      </participant>

      <participant name="1">
        <domain_participant_qos>
```

```

    <transport_builtin>
      <mask>UDpv4_WAN</mask>
      <udpv4_wan>
        <public_address>40.20.23.56</public_address>
        <comm_ports>
          <default>
            <host>4500</host>
            <public>5678</public>
          </default>
        </comm_ports>
      </udpv4_wan>
    </transport_builtin>
  </domain_participant_qos>
</participant>

<session name="Session1">
  <auto_topic_route name="AllForward">
    <input participant="0">
      <allow_topic_name_filter>*</allow_topic_name_filter>
      <allow_registered_type_name_filter>*</allow_registered_type_name_filter>
    </input>
    <output participant="1">
      <allow_topic_name_filter>*</allow_topic_name_filter>
      <allow_registered_type_name_filter>*</allow_registered_type_name_filter>
    </output>
  </auto_topic_route>
</session>

<session name="Session2">
  <auto_topic_route name="AllBackward">
    <input participant="1">
      <allow_topic_name_filter>*</allow_topic_name_filter>
      <allow_registered_type_name_filter>*</allow_registered_type_name_filter>
    </input>
    <output participant="0">
      <allow_topic_name_filter>*</allow_topic_name_filter>
      <allow_registered_type_name_filter>*</allow_registered_type_name_filter>
    </output>
  </auto_topic_route>
</session>

  </domain_route>
</routing_service>
</dds>

```

Participant 0 in the domain route is the *DomainParticipant* that will be used to send/receive data from the internal *Connex* databus running in the data center network. The *DomainParticipant* is configured to use the builtin UDPv4 transport.

Participant 1 is used to send/receive data to/from the WAN, and it has the role of the External Participant described in Sub-scenario 2 in [52.4.1 Peer-to-Peer Communication between Internal Participant and External Participant](#) on page 995.

**Note:** By making Participant 1 reachable at a well-known public address 40.20.23.56:5678 (by configuring the data center's NAT router to do port forwarding), the system doesn't depend on the kinds of NATs in the vehicles and the rest of the components in the system. Communication is always allowed.

### 52.5.1.2 In-Vehicle Routing Service Configuration

```
<dds>
  <routing_service name="RS">
    <domain_route name="TwoWayDomainRoute">
      <participant name="0">
        <domain_participant_qos>
          <transport_builtin>
            <mask>UDPv4</mask>
          </transport_builtin>
        </domain_participant_qos>
      </participant>

      <participant name="1">
        <domain_participant_qos>
          <transport_builtin>
            <mask>UDPv4_WAN</mask>
          </transport_builtin>
          <discovery>
            <initial_peers>
              <element>0@udpv4_wan://40.20.23.56:5678</element>
            </initial_peers>
          </discovery>
        </domain_participant_qos>
      </participant>

      <session name="Session1">
        <auto_topic_route name="AllForward">
          <input participant="0">
            <allow_topic_name_filter>*</allow_topic_name_filter>
            <allow_registered_type_name_filter>*</allow_registered_type_name_filter>
          </input>
          <output participant="1">
            <allow_topic_name_filter>*</allow_topic_name_filter>
            <allow_registered_type_name_filter>*</allow_registered_type_name_filter>
          </output>
        </auto_topic_route>
      </session>

      <session name="Session2">
```

```

    <auto_topic_route name="AllBackward">
      <input participant="1">
        <allow_topic_name_filter>*</allow_topic_name_filter>
        <allow_registered_type_name_filter>*</allow_registered_type_name_filter>
      </input>
      <output participant="0">
        <allow_topic_name_filter>*</allow_topic_name_filter>
        <allow_registered_type_name_filter>*</allow_registered_type_name_filter>
      </output>
    </auto_topic_route>
  </session>

</domain_route>
</routing_service>
</dds>

```

Participant 0 in the domain route is the *DomainParticipant* that will be used to send/receive data from the internal *Connex*t databus running in the in-vehicle network. The *DomainParticipant* is configured to use the builtin UDPv4 transport.

Participant 1 is used to send/receive data to/from the WAN and it has the role of the Internal Participant described in Sub-scenario 2 in [52.4.1 Peer-to-Peer Communication between Internal Participant and External Participant on page 995](#).

Notice the use of the ‘0@’ as the participant ID limit in the `<initial_peers>` for Participant 1. This is done to minimize the amount of discovery traffic sent to the *Routing Service* running in the data center. There is no need to use a number different than 0 when using *Real-Time WAN Transport*. (You can, but there will be more traffic.) See [24.1 Peer Descriptor Format on page 326](#) for additional information on the participant ID limit.

## 52.5.2 Relayed Edge-to-Edge Deployment Scenario

For this deployment scenario, consider a webinar platform built using *Connex*t. In this use case, the platform provider does not have any control over the attendees or the presenter network environment, including the NAT configuration. Communication cannot be peer-to-peer for two main reasons:

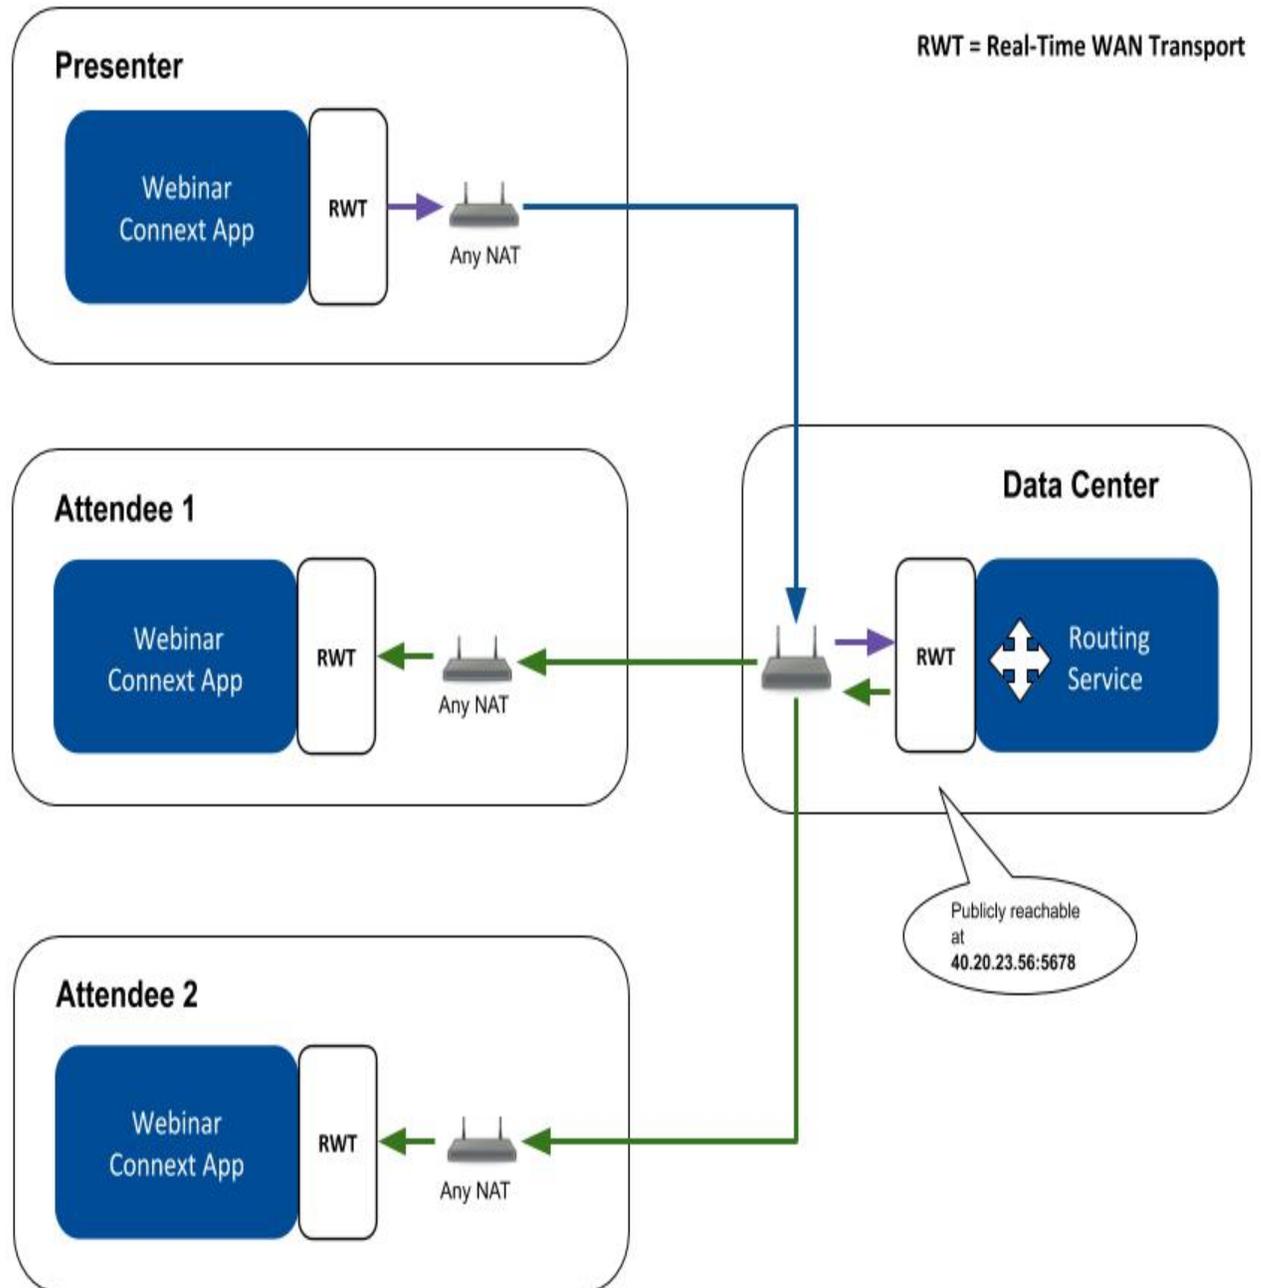

- The NATs environment is not known in advance.
- Communication is one-to-many. The presenter computer may not have enough resources (CPU and bandwidth) to broadcast the webinar content to all attendees.

To implement this use case, the *Connex*t application running in the presenter’s computer will distribute the webinar content to a *Routing Service* instance running in a data center or the cloud. Unlike in the edge-to-data center scenario, where *Routing Service* is used as a gateway distributing information to components that are running inside the cloud, in this scenario *Routing Service* is used as a relay service. The edge applications cannot communicate with each other directly, so in order to exchange messages,

an application sends the message to *Routing Service*, which relays this message to the other applications.

In this case, the *Routing Service* instance will be in charge of relaying the content to the different attendees. Note that, for the sake of simplicity, we only have one *Routing Service* in this example. In a real use case, there may be multiple *Routing Services* organized in a hierarchical manner relaying the signal to different sets of attendees.

Figure 52.11: Relayed Edge-to-Edge Communication

The following sections provide an example configuration for the scenario described in [Figure 52.11: Relayed Edge-to-Edge Communication on the previous page](#). The *Routing Service* instance is configured to propagate every *Topic* using an *AutoTopicRoute*.

### 52.5.2.1 Data Center Routing Service Configuration

```
<dds>
  <routing_service name="RS">
    <domain_route name="TwoWayDomainRoute">
      <participant name="1">
        <domain_participant_qos>
          <transport_builtin>
            <mask>UDpv4_WAN</mask>
            <udpv4_wan>
              <public_address>40.20.23.56</public_address>
              <comm_ports>
                <default>
                  <host>4500</host>
                  <public>5678</public>
                </default>
              </comm_ports>
            </udpv4_wan>
          </transport_builtin>
        </domain_participant_qos>
      </participant>

      <session name="Session1">
        <auto_topic_route name="AllForward">
          <input participant="1">
            <allow_topic_name_filter>*</allow_topic_name_filter>
            <allow_registered_type_name_filter>*</allow_registered_type_name_filter>
          </input>
          <output participant="1">
            <allow_topic_name_filter>*</allow_topic_name_filter>
            <allow_registered_type_name_filter>*</allow_registered_type_name_filter>
          </output>
        </auto_topic_route>
      </session>

      <session name="Session2">
        <auto_topic_route name="AllBackward">
          <input participant="1">
            <allow_topic_name_filter>*</allow_topic_name_filter>
            <allow_registered_type_name_filter>*</allow_registered_type_name_filter>
          </input>
          <output participant="1">
            <allow_topic_name_filter>*</allow_topic_name_filter>
            <allow_registered_type_name_filter>*</allow_registered_type_name_filter>
          </output>
        </auto_topic_route>
      </session>
    </domain_route>
  </routing_service>
</dds>
```

```

        </output>
      </auto_topic_route>
    </session>

  </domain_route>
</routing_service>
</dds>

```

The domain route in *Routing Service* only creates one Participant that is used to relay the webinar content and that has the role of the External Participant described in Sub-Scenario 2 in [52.4.1 Peer-to-Peer Communication between Internal Participant and External Participant on page 995](#). The *Routing Service* Participant is reachable at a well-known public IP transport address, 40.20.23.56:5678.

### 52.5.2.2 Webinar Application Configuration

```

<dds>
  <qos_profile name="WebinarParticipant">
    <domain_participant_qos>
      <transport_builtin>
        <mask>UDPv4_WAN</mask>
      </transport_builtin>
      <discovery>
        <initial_peers>
          <element>0@udpv4_wan://40.20.23.56:5678</element>
        </initial_peers>
      </discovery>
    </domain_participant_qos>
  </qos_profile>
</dds>

```

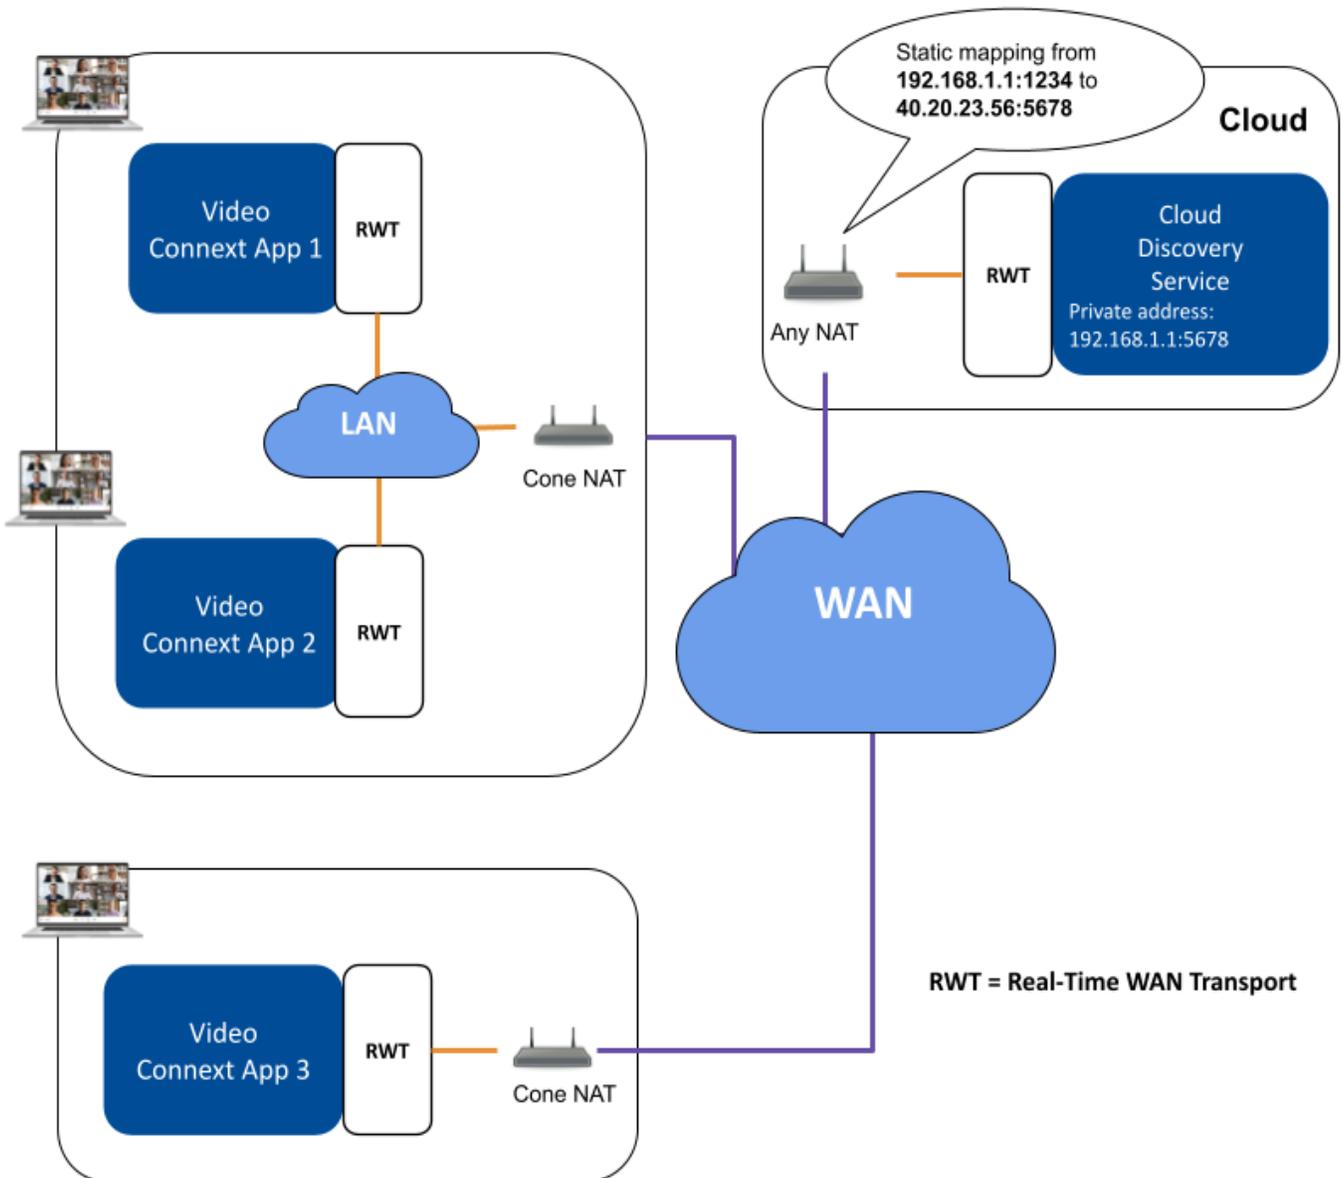

The Participant in the webinar application is used to send/receive webinar data to/from the WAN. This WebinarParticipant has the role of the Internal Participant described in Sub-scenario 2 in [52.4.1 Peer-to-Peer Communication between Internal Participant and External Participant on page 995](#).

Notice the use of the ‘0@’ participant index in the `<initial_peers>`. This is done to minimize the amount of discovery traffic sent to the *Routing Service* running in the data center. There is no need to use a number different than 0 when using *Real-Time WAN Transport*. (You can, but there will be more traffic.) See [24.1 Peer Descriptor Format on page 326](#) for additional information on the participant ID limit.

### 52.5.3 Peer-to-Peer, Edge-to-Edge Deployment Scenario

Currently, this scenario is only supported in environments in which the NATs involved in the communication are cone NATs. Consider a videoconferencing system in which users establish 1-1 calls with each other. Users communicate with other users within their own LAN and in different LANs across a WAN.

Figure 52.12: Peer-to-Peer and Edge-to-Edge Communication

Because each user is behind a cone NAT, the users can communicate peer-to-peer with other users across the WAN with the help of *Cloud Discovery Service* to facilitate both the NAT traversal process and the discovery of *DomainParticipants* as described in [52.4.2 Peer-to-Peer Communication between Two Internal Participants on page 998](#).

In addition, some users will be running in the same LAN. Because NAT loopback (see [52.3.6 NAT Hairpinning on page 994](#)) is not allowed by NAT routers in most cases, it is necessary to use the builtin UDPv4 transport in combination with the *Real-Time WAN Transport* to enable communications within the LAN.

The following sections provide an example configuration for the scenario described in [Figure 52.12: Peer-to-Peer and Edge-to-Edge Communication on the previous page](#).

### 52.5.3.1 Video Connex Application Configuration

```
<dds>
  <qos_profile name="VideoAppParticipant">
    <domain_participant_qos>
      <transport_builtin>
        <mask>UDpv4|UDpv4_WAN</mask>
      </transport_builtin>
      <discovery>
        <initial_peers>
          <element>udpv4://239.255.0.1</element>
          <element>rtps@udpv4_wan://40.20.23.56:5678</element>
        </initial_peers>
      </discovery>
      <discovery_config>
        <locator_reachability_assert_period>
          <sec>15</sec>
          <nanosec>0</nanosec>
        </locator_reachability_assert_period>
        <locator_reachability_lease_duration>
          <sec>60</sec>
          <nanosec>0</nanosec>
        </locator_reachability_lease_duration>
      </discovery_config>
    </domain_participant_qos>
  </qos_profile>
</dds>
```

Within the LAN, discovery is configured to be done over multicast by setting `<initial_peers>` to `udpv4://239.255.0.1`. Over the WAN, discovery will occur using *Cloud Discovery Service*.

### 52.5.3.2 Cloud Discovery Service Configuration

```
<dds>
  <cloud_discovery_service name="CDS">
    <transport>
      <element>
        <alias>builtin.udpv4_wan</alias>
        <receive_port>5678</receive_port>
        <property>
          <element>
            <name>dds.transport.UDpv4.builtin.public_address</name>
            <value>50.10.23.45</value>
          </element>
        </property>
      </element>
    </transport>
  </cloud_discovery_service>
</dds>
```

## 52.6 Enabling Real-Time WAN Transport

To use *Real-Time WAN Transport*, you have two options:

- **(Recommended for all platforms that support dynamic library loading)** Automatic dynamic loading of the transport library. This approach only requires you to make sure the *Real-Time WAN Transport* dynamic Release or Debug library is available in your library path. See the [RTI Connex Core Libraries Platform Notes](#) for the platforms that support dynamic *Real-Time WAN Transport* libraries. See [52.6.1 Dynamically Loading the Real-Time WAN Transport](#) below.
- Manual link against the applicable transport library. See the [RTI Connex Core Libraries Platform Notes](#) for a list of the *Real-Time WAN Transport* libraries available for your platform. See [52.6.2 Linking the Real-Time WAN Transport against your Application](#) below for details.

**Note:** Normally, you cannot mix static and dynamic libraries (see Building Applications chapter in the [RTI Connex Core Libraries Platform Notes](#)). For *Real-Time WAN Transport*, however, it is recommended that you load the library dynamically, regardless of how you load your core libraries. There is one exception: if your platform does not support dynamic loading, follow the instructions in [52.6.2 Linking the Real-Time WAN Transport against your Application](#) below for more information on how to link your application against the corresponding *Real-Time WAN Transport* library.

### 52.6.1 Dynamically Loading the Real-Time WAN Transport

The recommended way to use the transport is to let *Connex* automatically load the *Real-Time WAN Transport* dynamic library. (Not all platforms support dynamic loading. See the [RTI Connex Core Libraries Platform Notes](#) for details.)

To allow *Connex* to load the *Real-Time WAN Transport* dynamic library, simply make sure that the applicable *Real-Time WAN Transport* dynamic Release or Debug library is available in your system library search path (e.g., LD\_LIBRARY\_PATH in Linux systems, PATH on Windows systems, DYLD\_LIBRARY\_PATH on macOS systems).

### 52.6.2 Linking the Real-Time WAN Transport against your Application

If the method described in [52.6.1 Dynamically Loading the Real-Time WAN Transport](#) above is not available on your system (because your architecture does not support dynamic library loading), you can still use the *Real-Time WAN Transport* by linking your application against the transport library.

Compared with dynamic loading, you need to pay attention to two things:

First, include the *Real-Time WAN Transport* library in the list of libraries used during your application linking. See the [RTI Connex Core Libraries Platform Notes](#) for the specific library to link for your target platform.

Second, manually tell *Connex* the pointer to the function of the entry point of the *Real-Time WAN Transport* library before you create the *DomainParticipant*. Setting this pointer requires setting the `dds.transport.UDPv4_WAN.builtin.plugin_enabled_function_ptr` property. (See [52.8.1 Setting Real-Time WAN Transport Properties on page 1016](#).) Here is an example of how to set this pointer in code:

```
/* Include the symbol for NDDS_Transport_UDP_WAN_Library_is_plugin_enabled */
#include "transport/transport_udp_wan_library.h"

/* The property name "dds.transport.UDPv4_WAN.builtin.plugin_enabled_function_ptr"
 * indicates the entry point for the Real-Time WAN Transport library.
 * The value MUST be the stringified value of the function pointer of
 * NDDS_Transport_UDP_WAN_Library_is_plugin_enabled. Note that
 * add_pointer_property() API will automatically convert the
 * function pointer to a string.
 */
if (DDS_PropertyQosPolicyHelper_add_pointer_property(
    &participantQos.property,
    "dds.transport.UDPv4_WAN.builtin.plugin_enabled_function_ptr",
    (void *) NDDS_Transport_UDP_WAN_Library_is_plugin_enabled)
    != DDS_RETCODE_OK) {
    /* error */
}
```

## 52.7 Transport Initial Peers

The initial peers (see [44.2.2 Setting the ‘Initial Peers’ List on page 700](#)) for *Real-Time WAN Transport* have the following form:

```
0 @ udpv4_wan :// <peer_public_IP_address> <peer_public_port>
```

Notice that the participant ID limit should always be ‘0@’, since there can be only one *DomainParticipant* associated with the public IP transport address `<peer_public_IP_address>:<peer_public_port>`. Note that a participant ID limit different than 0 will be accepted, but it will generate more discovery traffic than necessary.

`<peer_public_IP_address>:<peer_public_port>` defines the public IP transport address at which the remote *DomainParticipant* is reachable. For example, assume the following configuration for a remote *DomainParticipant*:

```
<dds>
  <qos_profile name="ExternalParticipant">
    <domain_participant_qos>
      <transport_builtin>
        <mask>UDPv4_WAN</mask>
        <udpv4_wan>
          <public_address>50.10.23.45</public_address>
          <comm_ports>
            <default>
```

```

        <host>1234</host>
        <public>2345</public>
    </default>
</comm_ports>
</udpv4_wan>
</transport_builtin>
</domain_participant_qos>
</qos_profile>
</dds>

```

The initial peer that can be used to establish communication with the remote *DomainParticipant* is:

```
0 @ udpv4_wan :// 50.10.23.45 2345
```

For scenarios in which *Cloud Discovery Service* (CDS) is involved, the initial peers have the following form:

```
rtps @ udpv4_wan :// <CDS_public_IP_address> <CDS_public_port>
```

<CDS\_public\_IP\_address>:<CDS\_public\_port> defines the public IP transport address at which CDS is reachable. For example, assume the following CDS configuration:

```

<dds>
  <cloud_discovery_service name="CDS">
    <transport>
      <element>
        <alias>builtin.udpv4_wan</alias>
        <receive_port>5678</receive_port>
        <property>
          <element>
            <name>dds.transport.UDPv4.builtin.public_address</name>
            <value>50.10.23.45</value>
          </element>
        </property>
      </element>
    </transport>
  </cloud_discovery_service>
</dds>

```

The initial peer that can be used to establish communication with CDS is:

```
rtps @ udpv4_wan :// 50.10.23.45 5678
```

## 52.8 Transport Configuration

*Real-Time WAN Transport* is a transport plugin that can be configured in three different ways:

- Programmatically by calling `set_builtin_transport_property()` (see [51.5 Setting Builtin Transport Properties of Default Transport Instance—get/set\\_builtin\\_transport\\_properties\(\)](#) on page 959).
- By specifying predefined property strings in the *DomainParticipant's* `PropertyQosPolicy` (see [51.6 Setting Builtin Transport Properties with the PropertyQosPolicy](#) on page 960).
- By using the tag `<domain_participant_qos>/<transport_builtin>/<udpv4_wan>` in the XML configuration.

## 52.8.1 Setting Real-Time WAN Transport Properties

Table 52.1 [Properties for Real-Time WAN Transport](#) describes the configuration parameters for *Real-Time WAN Transport*:

Table 52.1 Properties for *Real-Time WAN Transport*

XML tag (under <code>&lt;udpv4_wan&gt;</code> )	Property Name (prefix with 'dds.transport.UDPv4_ WAN.builtin.')	Property Value Description
General Transport Properties		
<code>&lt;gather_send_buffer_count_max&gt;</code>	<code>parent.gather_send_buffer_count_max</code>	<p>Specifies the maximum number of buffers that <i>Connex</i>t can pass to the <code>send()</code> method of a transport plugin.</p> <p>The transport plugin <code>send()</code> API supports a gather-send concept, where the <code>send()</code> call can take several discontinuous buffers, assemble and send them in a single message. This enables <i>Connex</i>t to send a message from parts obtained from different sources without first having to copy the parts into a single contiguous buffer.</p> <p>However, most transports that support a gather-send concept have an upper limit on the number of buffers that can be gathered and sent. Setting this value will prevent <i>Connex</i>t from trying to gather too many buffers into a send call for the transport plugin.</p> <p><i>Connex</i>t requires all transport-plugin implementations to support a gather-send of least a minimum number of buffers. This minimum number is <code>NDDS_TRANSPORT_PROPERTY_GATHER_SEND_BUFFER_COUNT_MIN</code>.</p> <p>See <a href="#">51.6.1 Setting the Maximum Gather-Send Buffer Count for UDP Transports on page 977</a>.</p> <p>Default: 16</p>
<code>&lt;message_size_max&gt;</code>	<code>parent.message_size_max</code>	<p>The maximum size of a message in bytes that can be sent or received by the transport plugin. Above this size, DDS-level fragmentation will occur. See <a href="#">34.3 Large Data Fragmentation on page 524</a>.</p> <p>This value must be set before the transport plugin is registered, so that <i>Connex</i>t can properly use the plugin.</p> <p>Default for Integrity platforms: 9216 Default for non-Integrity platforms: 65507</p>

XML tag (under <udpv4_wan>)	Property Name (prefix with 'dds.transport.UDPv4_ WAN.builtin.')	Property Value Description
<allow_interfaces_list>	parent.allow_interfaces_list	<p>A list of strings, each identifying a range of interface addresses or an interface name.</p> <p>As a property value, interfaces must be specified as comma-separated strings, with each comma delimiting an interface. In XML, they are provided as a set of elements (&lt;element&gt;) under &lt;allow_interfaces_list&gt;. For example, the following are acceptable strings:</p> <p>192.168.1.1 192.168.1.* 192.168.* 192.* ether0</p> <p>If the list is non-empty, this "white" list is applied before the <b>parent.deny_interfaces_list</b> list.</p> <p>The <i>DomainParticipant</i> will use the resulting list of interfaces to inform its remote participant(s) about which unicast addresses may be used to contact the <i>DomainParticipant</i>.</p> <p><b>Note:</b> This property does not affect the interfaces that the transport uses to send unicast data <i>from</i> that <i>DomainParticipant</i>. That decision is made by the OS based on the destination address.</p> <p>You must manage the memory of the list. The memory may be freed after the <i>DomainParticipant</i> is deleted.</p> <p>The left-to-right order of this list matters if you are using the <b>max_interface_count</b> to limit the allowable interfaces further. See <b>max_interface_count</b>.</p> <p>Default: empty list that represents all available interfaces</p>
<deny_interfaces_list>	parent.deny_interfaces_list	<p>A list of strings, each identifying a range of interface addresses or an interface name. If the list is non-empty, deny the use of these interfaces.</p> <p>As a property value, interfaces must be specified as comma-separated strings, with each comma delimiting an interface. In XML, they are provided as a set of elements (&lt;element&gt;) under &lt;deny_interfaces_list&gt;. For example, the following are acceptable strings:</p> <p>192.168.1.1 192.168.1.* 192.168.* 192.* ether0</p> <p>This "black" list is applied after the <b>parent.allow_interfaces_list</b> and filters out the interfaces that should not be used for receiving data. The resulting list restricts <i>reception</i> to a particular set of interfaces for unicast UDP.</p> <p><b>Note:</b> This property does not affect the interfaces that the transport uses to send unicast data <i>from</i> the <i>DomainParticipant</i>. That decision is made by the OS based on the destination address.</p> <p>You must manage the memory of the list. The memory may be freed after the <i>DomainParticipant</i> is deleted.</p> <p>Default: empty list that represents no deny interfaces</p>

XML tag (under <udpv4_wan>)	Property Name (prefix with 'dds.transport.UDPv4_ WAN.builtin.')	Property Value Description
<max_interface_count>	parent.max_interface_count	<p>How many of the addresses in your allowed interfaces list are used, at most, at any time.</p> <p>This feature is useful if you want to control the network interfaces on which your <i>DomainParticipants</i> receive data. For example, if you have one wired and one wireless interface in your allowed interfaces list <i>both</i> up and running, and <b>max_interface_count</b> is set to 1, the <i>DomainParticipant</i> will receive data over the interface you list first in the <b>allow_interfaces_list</b>—for example, the wired one. If the wired interface is not in use (for example, the device is undocked), then the <i>DomainParticipant</i> will receive data only over the next available up-and-running interface in your <b>allow_interfaces_list</b>, which would be the wireless one.</p> <p><i>Connex</i>t selects the preferred interface(s) by iterating over the list of allowed interfaces until the first <b>max_interfaces_count</b> of active interfaces encountered are announced. The order of iteration is left to right as specified in the <b>allow_interfaces_list</b> setting.</p> <p>This setting applies only if the <b>allow_interfaces_list</b> is not empty.</p> <p>The <b>max_interface_count</b> setting does not consider end-to-end connectivity to select interfaces. The decision is based purely on whether interfaces are up or down in a node. Therefore, this feature is not intended to be used in the following scenarios:</p> <ul style="list-style-type: none"> <li>• A <i>DomainParticipant</i> is not reachable by other <i>DomainParticipants</i> in all the interfaces in the <b>allow_interfaces_list</b>. This could occur if the <i>DomainParticipant</i> is in different subnets, and some of these subnets cannot be reached by other <i>DomainParticipants</i>.</li> <li>• End-to-end connectivity issues lead to situations in which the interfaces selected after applying <b>max_interface_count</b> cannot be reached by other <i>DomainParticipants</i>.</li> </ul> <p><b>Note:</b> If a pattern string in the <b>allow_interfaces_list</b> matches multiple interface addresses, and <b>max_interface_count</b> is set to a finite value, the order for the matching allowed interfaces is decided based on the order in which the operating system provides these interfaces.</p> <p>Default: LENGTH_UNLIMITED Range: [1, LENGTH_UNLIMITED]</p>
<properties_bitmap>	parent.properties_bitmap	<p>A bitmap that defines various properties of the transport to the <i>Connex</i>t core. Currently, the only property supported is whether or not the transport plugin will always loan a buffer when <i>Connex</i>t tries to receive a message using the plugin. This is in support of a zero-copy interface.</p> <p>Default: 0</p>

XML tag (under <udpv4_wan>)	Property Name (prefix with 'dds.transport.UDPv4_WAN.builtin.')	Property Value Description
N/A	property_validation_action	<p>By default, property names given in the <a href="#">47.19 PROPERTY QosPolicy (DDS Extension) on page 837</a> are validated to avoid using incorrect or unknown names (for example, due to a typo). This property configures the validation of the property names associated with the transport:</p> <ul style="list-style-type: none"> <li>• VALIDATION_ACTION_EXCEPTION: validate the properties. Upon failure, log errors and fail.</li> <li>• VALIDATION_ACTION_SKIP: skip validation.</li> <li>• VALIDATION_ACTION_WARNING: validate the properties. Upon failure, log warnings and do not fail.</li> </ul> <p>If this property is not set, the property validation behavior will be the same as that of the <i>DomainParticipant</i>, which by default is VALIDATION_ACTION_EXCEPTION. See <a href="#">47.19.1 Property Validation on page 840</a> for more information.</p>
<thread_name_prefix>	thread_name_prefix	<p>If you do not set this field, <i>Connex</i>t creates the following prefix:</p> <p>'r' + 'Tr' + participant identifier + '\0'</p> <p>Where 'r' indicates this is a thread from RTI, 'Tr' indicates the thread is related to a transport, and participant identifier contains 5 characters as follows:</p> <ul style="list-style-type: none"> <li>• If <b>participant_name</b> is set: The participant identifier will be the first 3 characters and the last 2 characters of the <b>participant_name</b>.</li> <li>• If <b>participant_name</b> is not set, then the identifier is computed as <b>domain_id</b> (3 characters) followed by <b>participant_id</b> (2 characters).</li> <li>• If <b>participant_name</b> is not set and the <b>participant_id</b> is set to -1 (default value), then the participant identifier is computed as the last 5 digits of the <b>rtps_instance_id</b> in the participant GUID.</li> </ul> <p>See <a href="#">Chapter 72 Identifying Threads Used by Connex</a>t on page 1196.</p>
<b>General UDP Properties</b>		
<protocol_overhead_max>	protocol_overhead_max	<p>Maximum size in bytes of protocol overhead, including headers.</p> <p>This value is the maximum size, in bytes, of protocol-related overhead. Normally, the overhead accounts for UDP and IP headers. The default value is set to accommodate the most common UDP/IP header size.</p> <p>Note that when <b>parent.message_size_max</b> plus this overhead is larger than the UDPv4 maximum message size (65535 bytes), the middleware will automatically reduce the effective <b>message_size_max</b> to 65535 minus this overhead.</p> <p>Default: 28</p>

XML tag (under <udpv4_wan>)	Property Name (prefix with 'dds.transport.UDPv4_WAN.builtin.')	Property Value Description
<send_socket_buffer_size>	send_socket_buffer_size	<p>Size in bytes of the send buffer of a socket used for sending. On most operating systems, <b>setsockopt()</b> will be called to set the SENDBUF to the value of this parameter.</p> <p>This value must be greater than or equal to <b>parent.message_size_max</b>. The maximum value is operating system-dependent.</p> <p>If -1, <b>setsockopt()</b> (or equivalent) will not be called to size the send buffer of the socket. The transport will use the OS default.</p> <p>Default: 131072</p>
<recv_socket_buffer_size>	recv_socket_buffer_size	<p>Size in bytes of the receive buffer of a socket used for receiving. On most operating systems, <b>setsockopt()</b> will be called to set the RECVBUF to the value of this parameter.</p> <p>This value must be greater than or equal to <b>parent.message_size_max</b>. The maximum value is operating system-dependent.</p> <p>If -1, <b>setsockopt()</b> (or equivalent) will not be called to size the receive buffer of the socket. The transport will use the OS default.</p> <p>Default: 131072</p>
<ignore_loopback_interface>	ignore_loopback_interface	<p>Prevents the transport plugin from using the IP loopback interface. Three values are allowed:</p> <ul style="list-style-type: none"> <li>• 0: Forces local traffic to be sent over loopback, even if a more efficient transport (such as shared memory) is installed (in which case traffic will be sent over both transports).</li> <li>• 1: Disables local traffic via this plugin. The IP loopback interface will not be used, even if no NICs are discovered. This is useful when you want applications running on the same node to use a more efficient transport (such as shared memory) instead of the IP loopback.</li> <li>• -1: Automatic. Enables local traffic via this plugin. To avoid redundant traffic, <i>Connex</i>t will selectively ignore the loopback destinations that are also reachable through shared memory.</li> </ul> <p>Default: -1</p>
DEPRECATED N/A	DEPRECATED ignore_nonup_interfaces	<p>This property is only supported on Windows platforms with statically configured IP addresses.</p> <p>It allows/disallows the use of interfaces that are not reported as UP (by the operating system) in the UDPv4_WAN transport. Two values are allowed:</p> <ul style="list-style-type: none"> <li>• 0: Allow interfaces that are reported as DOWN. <ul style="list-style-type: none"> <li>• Setting this value to 0 supports communication scenarios in which interfaces are enabled after the participant is created. Once the interfaces are enabled, discovery will not occur until the participant sends the next periodic announcement (controlled by the parameter <b>participant_qos.discovery_config.participant_liveliness_assert_period</b>).</li> <li>• To reduce discovery time, you may want to decrease the value of <b>participant_liveliness_assert_period</b>. For the above scenario, there is one caveat: non-UP interfaces must have a static IP assigned.</li> </ul> </li> <li>• 1: Do not allow interfaces that are reported as DOWN.</li> </ul> <p>Default: 1</p>

XML tag (under <udpv4_wan>)	Property Name (prefix with 'dds.transport.UDPv4_ WAN.builtin.')	Property Value Description
<ignore_nonrunning_interfaces>	ignore_nonrunning_interfaces	<p>Prevents the transport plugin from using a network interface that is not reported as RUNNING by the operating system.</p> <p>The transport checks the flags reported by the operating system for each network interface upon initialization. An interface which is not reported as UP will not be used. This property allows the same check to be extended to the IFF_RUNNING flag implemented by some operating systems. The RUNNING flag is defined to mean that "all resources are allocated", and may be off if there is no link detected, e.g., the network cable is unplugged. Two values are allowed:</p> <ul style="list-style-type: none"> <li>• 0: Do not check the RUNNING flag when enumerating interfaces, just make sure the interface is UP.</li> <li>• 1: Check the flag when enumerating interfaces, and ignore those that are not reported as RUNNING. This can be used on some operating systems to cause the transport to ignore interfaces that are enabled but not connected to the network.</li> </ul> <p>By default this property is set to 1, so <i>Connex</i>t will ignore non-running interfaces.</p>
DEPRECATED N/A	DEPRECATED no_zero_copy	<p>Prevents the transport plugin from doing a zero copy.</p> <p>By default, this plugin will use the zero copy on OSs that offer it. While this is good for performance, it may sometimes tax the OS resources in a manner that cannot be overcome by the application.</p> <p>The best example is if the hardware/device driver lends the buffer to the application itself. If the application does not return the loaned buffers soon enough, the node may error or malfunction. In case you cannot reconfigure the hardware, device driver, or the OS to allow the zero-copy feature to work for your application, you may have no choice but to turn off zero-copy.</p> <p>By default this is set to 0, so <i>Connex</i>t will use the zero-copy API if offered by the OS.</p>
<send_blocking>	send_blocking	<p>Controls the blocking behavior of send sockets. <b>CHANGING THIS FROM THE DEFAULT CAN CAUSE SIGNIFICANT PERFORMANCE PROBLEMS.</b> Currently two values are defined:</p> <ul style="list-style-type: none"> <li>• 1 (NDDS_TRANSPORT_UDP_BLOCKING_ALWAYS): Sockets are blocking (default socket options for operating system).</li> <li>• 0 (NDDS_TRANSPORT_UDP_BLOCKING_NEVER): Sockets are modified to make them non-blocking. <b>This may cause significant performance problems.</b></li> </ul> <p>Default: 1</p>

XML tag (under <udpv4_wan>)	Property Name (prefix with 'dds.transport.UDPv4_WAN.builtin.')	Property Value Description
<transport_priority_mask>	transport_priority_mask	<p>Sets the mask for the transport priority field. This is used in conjunction with <b>transport_priority_mapping_low</b> and <b>transport_priority_mapping_high</b> to define the mapping from the <a href="#">47.26 TRANSPORT_PRIORITY QoSPolicy on page 856</a> to the IPv4 TOS field. Defines a contiguous region of bits in the 32-bit transport priority value that is used to generate values for the IPv4 TOS field on an outgoing socket.</p> <p>For example, the value 0x0000ff00 causes bits 9-16 (8 bits) to be used in the mapping. The value will be scaled from the mask range (0x0000 - 0xff00 in this case) to the range specified by low and high.</p> <p>If the mask is set to zero, then the transport will not set IPv4 TOS for send sockets.</p> <p>Default: 0</p>
<transport_priority_mapping_low>	transport_priority_mapping_low	<p>Sets the low and high values of the output range to IPv4 TOS.</p> <p>These values are used in conjunction with <b>transport_priority_mask</b> to define the mapping from the <a href="#">47.26 TRANSPORT_PRIORITY QoSPolicy on page 856</a> to the IPv4 TOS field. Defines the low and high values of the output range for scaling.</p>
<transport_priority_mapping_high>	transport_priority_mapping_high	<p>Note that IPv4 TOS is generally an 8-bit value.</p> <p>Default: 0 for <b>transport_priority_mapping_low</b> and 0xFF for <b>transport_priority_mapping_high</b></p>
<send_ping>	send_ping	<p>This property specifies whether to send a PING message before commencing the discovery process. On certain operating systems or with certain switches the initial UDP packet, configuring the ARP table, was unfortunately dropped. To avoid dropping the initial RTPS discovery sample, a PING message is sent to preconfigure the ARP table in those environments.</p> <p>Default: 1</p>
<use_checksum>	use_checksum	<p>This property specifies whether the UDP checksum will be computed. On Windows and Linux systems, the UDP checksum will not be set when <b>use_checksum</b> is set to 0. This is useful when RTPS protocol statistics related to corrupted messages need to be collected through the operation <b>get_participant_protocol_status()</b> (see <a href="#">16.3.14 Getting Participant Protocol Status on page 105</a>).</p> <p>Default: 1</p>
<b>IP Mobility Properties</b>		
<interface_poll_period>	interface_poll_period	<p>Specifies the period in milliseconds to query for changes in the state of all the interfaces.</p> <p>When possible, the detection of an IP address changes is done asynchronously using the APIs offered by the underlying OS. If there is no mechanism to do that, the detection will use a polling strategy where the polling period can be configured by setting this property.</p> <p>Default: 500</p>

XML tag (under <udpv4_wan>)	Property Name (prefix with 'dds.transport.UDPv4_ WAN.builtin.')	Property Value Description
<force_interface_poll_detection>	force_interface_poll_detection	<p>This property forces the interface tracker to use a polling method to detect changes to the network interfaces in IP mobility scenarios. It only applies to operating systems that support asynchronous notifications of interface changes.</p> <p>If set to TRUE, the interface tracker will use a polling method that queries the interfaces periodically to detect the changes. If set to FALSE, the interface tracker will use the operating system's default method.</p> <p>Basically, this property allows you—for an operating system that supports asynchronous notification—to use the polling method instead.</p> <p>Default: FALSE</p>
<disable_interface_tracking>	disable_interface_tracking	<p>Disables detection of network interface changes.</p> <p>By default, network interfaces changes are propagated in the form of locators to other applications. This is done to support IP mobility scenarios. For example, you could start an application with Wi-Fi and move to a wired connection. In order to continue communicating with other applications, this interface change must be propagated.</p> <p>You can disable the notification and propagation of interface changes by setting this property to 1.</p>
<b>WAN Properties</b>		
<public_address>	public_address	<p>Public IP address associated with the transport instantiation. The address is the public IP address of the NAT-enabled router that provides access to the WAN.</p> <p>Setting the public IP address is only necessary for the <i>Real-Time WAN Transport</i> associated with an external <i>DomainParticipant</i> in order to support the communication scenario described in <a href="#">52.4.1 Peer-to-Peer Communication between Internal Participant and External Participant on page 995</a>.</p> <p>When this property is set, the <i>DomainParticipant</i> will announce PUBLIC+UUID locators to other <i>DomainParticipants</i>. These locators are reachable locators because they contain a public IP transport address for the <i>DomainParticipant</i>. For additional information on <i>Real-Time WAN Transport</i> locators, see <a href="#">52.10.1 Transport Locators on page 1032</a>.</p> <p>By default, the public address is not set.</p>

XML tag (under <udpv4_wan>)	Property Name (prefix with 'dds.transport.UDPv4_ WAN.builtin.')	Property Value Description
<binding_ping_period>	binding_ping_period	<p>Configures the period in milliseconds at which BINDING_PING messages are sent by a local transport instance to a remote transport instance. For example, 1000 means to send BINDING_PING messages every second.</p> <p>BINDING_PING messages are used on the sending side to open NAT bindings from a local transport instance to a remote transport instance and they are sent periodically to keep the bindings open.</p> <p>For additional information on the role of BINDING_PING messages opening NAT bindings, see <a href="#">52.10.3 Communication Establishment Protocol for Peer-to-Peer Communication with Participants behind Cone NATs on page 1034</a>.</p> <p>On the receiving side, BINDING_PINGS are used to calculate the public IP transport address of a UUID locator. This address will be used to send data to the locator.</p> <p>For additional information on the role of BINDING_PING to associate UUID locators to public IP transport addresses, see <a href="#">52.10.4 Communication Establishment Protocol for Peer-to-Peer Communication with a Participant that has a Public Address on page 1037</a>.</p> <p>From a configuration point of view, and to avoid communication disruptions, the period at which a transport instance sends BINDING_PING messages should be smaller than the NAT binding session timeout. This timeout depends on the NAT router configuration.</p> <p>Default: 1000 (1 sec)</p>
<port_offset>	port_offset	<p>This property allows using the builtin UDPv4 transport and the <i>Real-Time WAN Transport</i> at the same time.</p> <pre data-bbox="878 1136 1224 1205">&lt;transport_builtin&gt;   &lt;mask&gt;UDPv4_WAN UDPv4&lt;/mask&gt; &lt;/transport_builtin&gt;</pre> <p>When the UDP ports used by <i>Real-Time WAN Transport</i> are not explicitly set, they are calculated as follows: RTPS port + port_offset. See <a href="#">52.8.2 Managing UDP Ports Used for Communication on the next page</a> for additional details.</p> <p>Default: 125</p>

## 52.8.2 Managing UDP Ports Used for Communication

### 52.8.2.1 Receiving Data

By default, *Real-Time WAN Transport* uses one UDP port per RTPS port to receive data. The UDP port number is calculated as RTPS port + port\_offset.

A *DomainParticipant* uses two RTPS ports, one for discovery and one for user data. Therefore, *Real-Time WAN Transport* uses two UDP ports out-of-the-box. For information on how the RTPS ports are obtained, see [44.9.2 Ports Used for Discovery on page 732](#).

You can also configure a specific *DataWriter* and *DataReader* to receive unicast data in a different RTPS port by configuring the [47.28 TRANSPORT\\_UNICAST QosPolicy \(DDS Extension\) on page 859](#)). This will also lead to the usage of a different UDP port by *Real-Time WAN Transport*.

There are two main use cases in which the default mapping from RTPS ports to UDP ports is not suitable:

- The first use case involves the configuration of the External Participant described in [52.4.1 Peer-to-Peer Communication between Internal Participant and External Participant on page 995](#). In this use case, you must be able to select the private and public UDP ports used for communication because you have to create a static NAT binding on the router for the External Participant.
- The second use case involves the use of UDP load balancers. With UDP load balancers, you must be able to configure a single UDP port to handle all data reception because the load balancer would not know how to map different ports to the same *DomainParticipant*.

For these use cases, *Real-Time WAN Transport* provides a way to specify the private and public UDP ports that will be used to serve specific RTPS ports.

#### 52.8.2.1.1 Changing the UDP Port Mapping

The <comm\_ports> XML tag or the property **dds.transport.UDIPv4\_WAN.builtin.comm\_ports** can be used to change the mapping of UDP ports to RTPS ports.

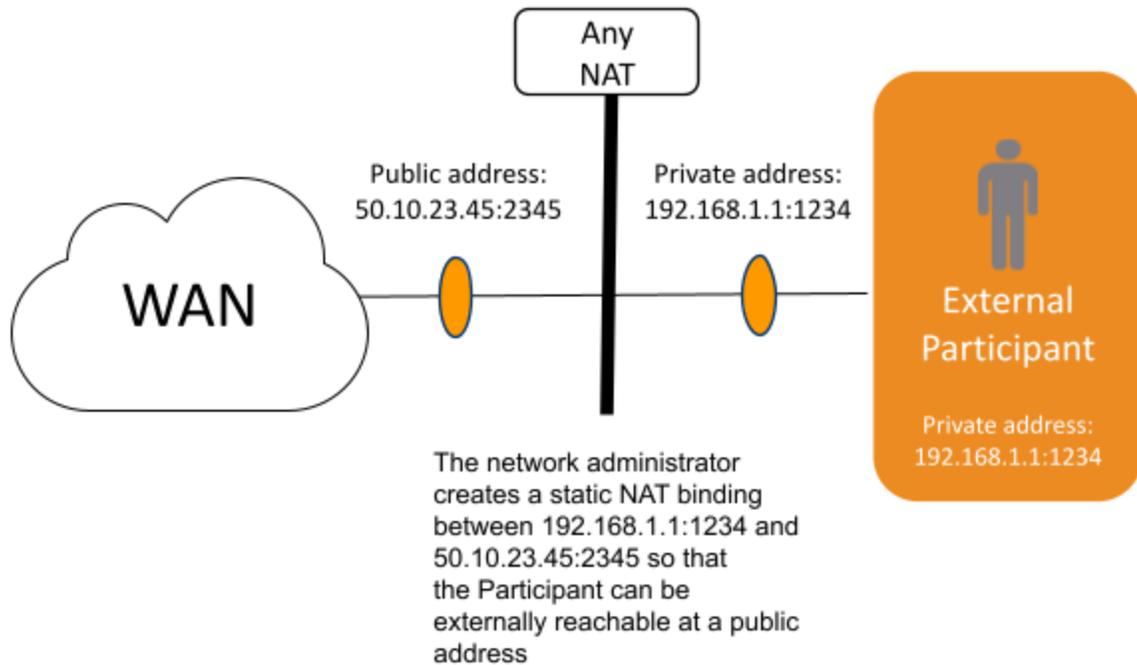

You can specify a list of mappings from an RTPS port to a host, and (optionally) a public UDP port. For RTPS ports that are not part of the list, you can provide a default mapping.

When the property **dds.transport.UDIPv4\_WAN.builtin.comm\_ports** is used instead of XML, the list is a JSON string.

#### 52.8.2.1.2 Configuring the Transport to Use a Single Port for an External Participant behind a NAT

This configuration will be needed for the External Participant behind a NAT in the scenario described in [52.4.2 Peer-to-Peer Communication between Two Internal Participants on page 998](#).

Figure 52.13: Single Port External Participant

XML:

```
<udpv4_wan>
  <comm_ports>
    <default>
      <host>1234</host>
      <public>2345</public>
    </default>
  </comm_ports>
</udpv4_wan>
```

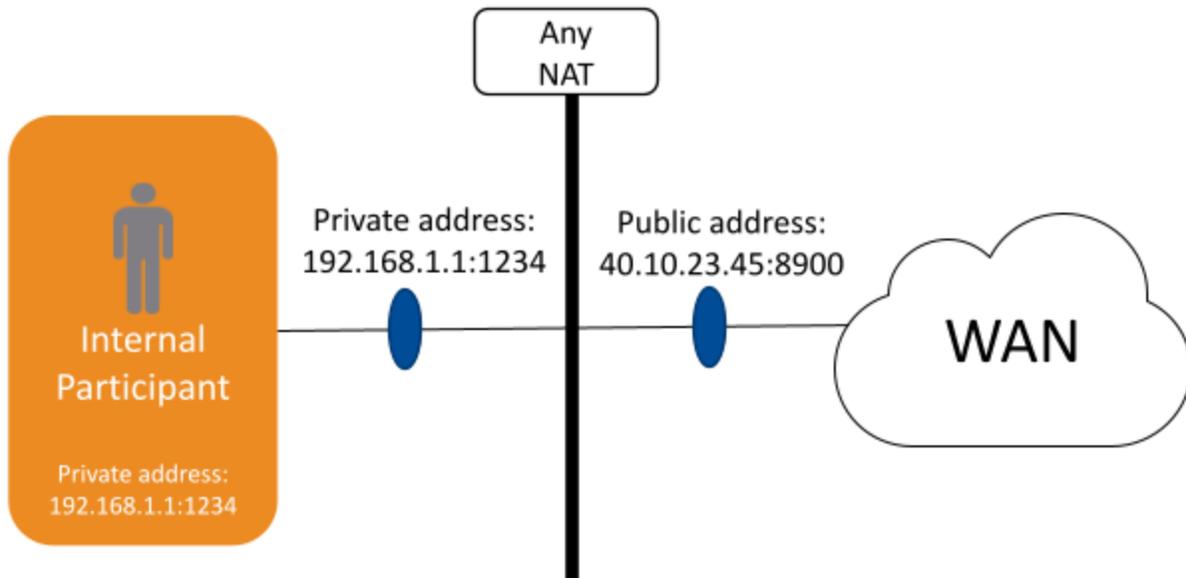

Property `dds.transport.UDPv4_WAN.builtin.comm_ports`:

```
{
  "default": {
    "host": 1234,
    "public": 2345
  }
}
```

### 52.8.2.2 Configuring the Transport to Use a Single Port for an Internal Participant behind a NAT

For the Internal Participants behind NATs used in the scenarios described in [52.4 Communication Scenarios on page 995](#), it is not necessary to configure the public port. The public port will be automatically assigned by the NAT once packages are sent from the private address.

Figure 52.14: Single Port Internal Participant

The mapping between the private address 192.168.1.1:1234 and the public address 40.10.23.45:8900 is automatically created by the NAT-enabled device when the Internal Participant sends a packet out

XML:

```
<udpv4_wan>
  <comm_ports>
    <default>
      <host>1234</host>
    </default>
  </comm_ports>
</udpv4_wan>
```

Property `dds.transport.UDPv4_WAN.builtin.comm_ports`:

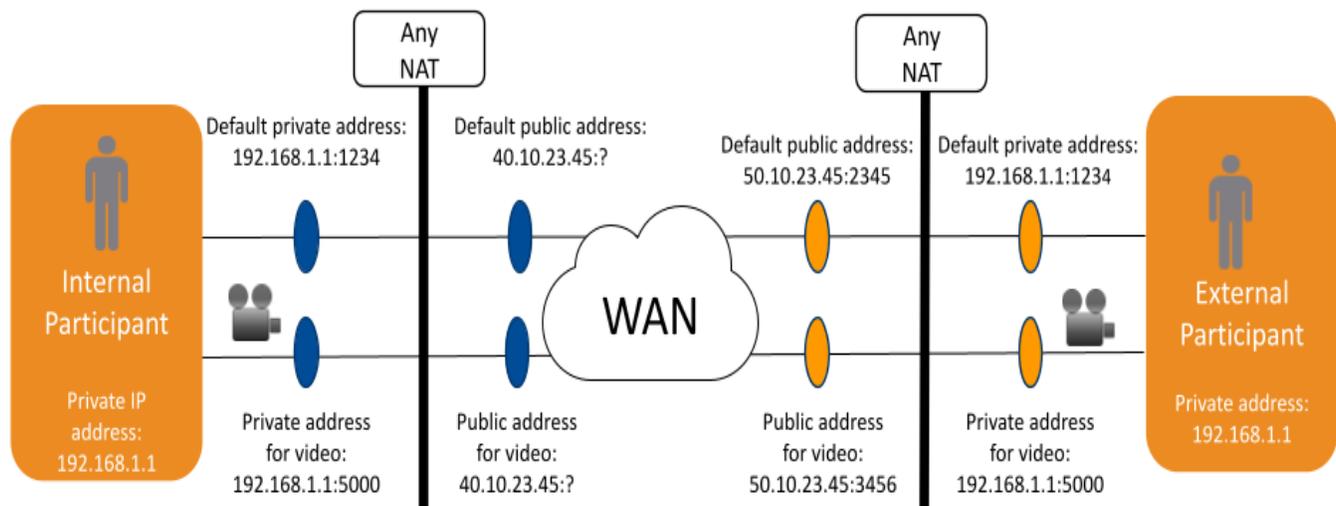

```
{
  "default": {
    "host": 1234,
  }
}
```

}

### 52.8.2.3 Configuring the Transport to Segregate Traffic for a Topic in its own Port

In some cases, you may want to segregate the RTPS traffic for a *Topic*, such as a *Video Topic*, in its own port. This *Topic* will get its own socket and receive a socket buffer. It will also get its own receive thread, which will make data reception on the *Topic* completely concurrent. For details on the middleware threads, see [Part 11: Connex Threading Model on page 1180](#).

Figure 52.15: Traffic Segregation in Different Port

#### 52.8.2.3.1 External Participant Configuration

```
<dds>
  <qos_profile name="ExternalParticipant">
    <domain_participant_qos>
      <transport_builtin>
        <mask>UDpv4_WAN</mask>
        <udpv4_wan>
          <public_address>50.10.23.45</public_address>
          <comm_ports>
            <default>
              <host>1234</host>
              <public>2345</public>
            </default>
            <mappings>
              <element>
                <rtps>5001</rtps>
                <host>5000</host>
                <public>3456</public>
              </element>
            </mappings>
          </comm_ports>
        </udpv4_wan>
      </transport_builtin>
    </domain_participant_qos>
  </qos_profile>
</dds>
```

```

    </domain_participant_qos>
  </qos_profile>

  <qos_profile name="VideoTopic" base_name="ExternalParticipant">
    <datareader_qos>
      <unicast>
        <value>
          <element>
            <receive_port>5001</receive_port>
            <transports>
              <element>udpv4_wan</element>
            </transports>
          </element>
        </value>
      </unicast>
    </datareader_qos>
  </qos_profile>
</dds>

```

To use a different port for the *Video Topic*, you will have to first change the [47.28 TRANSPORT\\_UNICAST QosPolicy \(DDS Extension\) on page 859](#) to specify an RTPS port (<unicast><receiver\_port>) for video data reception. Then, you will have to configure the mapping to UDP ports by updating the **comm\_ports** configuration.

If you choose to configure the **comm\_ports** using the property **dds.transport.UDPv4\_WAN.built-in.comm\_ports**, the following example will be the JSON string for the scenario described in [Figure 52.15: Traffic Segregation in Different Port on the previous page](#)

```

{
  "default": {
    "host": 1234,
    "Public": 2345
  }
  "mappings":
  [
    {
      "rtps": 5001,
      "Host": 5000,
      "Public": 3456
    }
  ]
}

```

#### 52.8.2.4 Sending Data

Data is always sent from a single UDP port. There is no way to send data using different UDP ports for different *Topics*.

The UDP port used for sending data corresponds to the port associated with the discovery RTPS port according to the rules described in [52.8.2.1 Receiving Data on page 1025](#). When the <comms\_port><default> is defined, the port used for sending data is the one provided in <comms\_port><default>.

## 52.8.3 Disabling IP Fragmentation for Real-Time WAN Transport

For WAN communications, it is not a good idea to rely on IP fragmentation. IP fragmentation causes significant issues in UDP, where there is no integrated support for a path MTU (maximum transmission unit) discovery protocol as there is in TCP. These are some of the problems associated with IP fragmentation:

- To successfully reassemble a packet, all fragments must be delivered. If a fragment is lost, the whole packet will be lost.
- Before reassembly, a host must hold partial fragment datagrams in memory. This opens an opportunity for memory exhaustion attacks.
- Subsequent fragments lack the higher-layer header. The TCP or UDP header is only present in the first fragment, making it impossible for firewalls to filter fragment datagrams based on criteria like source or destination ports.

For more information on IP-level versus *Connex*-level fragmentation, see [34.3 Large Data Fragmentation on page 524](#).

This section describes how to disable IP fragmentation in *Connex* applications using the *RTI Real-Time WAN Transport*. Instead, *Connex* will be responsible for fragmentation, done at the RTPS level. The key changes involve:

- Setting the *Real-Time WAN Transport* MTU (<message\_size\_max>) to be smaller than the typical IP MTU of around 1500 bytes. The recommendation is to be even more conservative and set the transport MTU to 1400 bytes.
- Enabling DDS fragmentation for reliable *Topics* (user and built-in *Topics*) by configuring the [47.20 PUBLISH\\_MODE QosPolicy \(DDS Extension\) on page 843](#).

For example:

```
<qos_profile name="DisableIPFragmentationWAN">
  <domain_participant_qos>
    <discovery_config>
      <publication_writer_publish_mode>
        <kind>ASYNCHRONOUS_PUBLISH_MODE_QOS</kind>
      </publication_writer_publish_mode>
      <subscription_writer_publish_mode>
        <kind>ASYNCHRONOUS_PUBLISH_MODE_QOS</kind>
      </subscription_writer_publish_mode>
      <secure_volatile_writer_publish_mode>
        <kind>ASYNCHRONOUS_PUBLISH_MODE_QOS</kind>
      </secure_volatile_writer_publish_mode>
      <service_request_writer_publish_mode>
        <kind>ASYNCHRONOUS_PUBLISH_MODE_QOS</kind>
      </service_request_writer_publish_mode>
    </discovery_config>
  </domain_participant_qos>
</qos_profile>
```

```

</discovery_config>
<transport_builtin>
  <mask>UDPv4_WAN</mask>
  <udpv4_wan>
    <message_size_max>1400</message_size_max>
  </udpv4_wan>
</transport_builtin>
</domain_participant_qos>

<datawriter_qos>
  <publish_mode>
    <kind>ASYNCHRONOUS_PUBLISH_MODE_QOS</kind>
  </publish_mode>
</datawriter_qos>
</qos_profile>

```

Or, you can replace the above configuration by using the built-in XML snippet `Transport.UDP.WAN`, which does the same thing as the above example: it enables the WAN transport and disables IP fragmentation. You can use that snippet as follows:

```

<qos_profile name="DisableIPFragmentationWAN">
  <base_name>
    <element>Transport.UDP.WAN</element>
  </base_name>
</qos_profile>

```

The following XML shows what the `Transport.UDP.WAN` snippet sets, for reference:

```

<qos_profile name="Transport.UDP.WAN">
  <base_name>
    <element>BuiltinQosSnippetLib::Transport.UDP.AvoidIPFragmentation</element>
  </base_name>
  <domain_participant_qos>
    <transport_builtin>
      <mask>UDPv4_WAN</mask>
    </transport_builtin>
  </domain_participant_qos>
</qos_profile>

```

The `Transport.UDP.WAN` snippet is composed of the `Transport.UDP.AvoidIPFragmentation` snippet (described in [34.3.1 Avoiding IP-Level Fragmentation on page 527](#)), except that it changes the transport to `UDPv4_WAN`. (See [50.2.3.3 QoS Profile Composition on page 914](#) for more information on QoS snippets in XML files.)

**Note:** Batching does not currently support RTPS fragmentation. If you use batching, you will currently not be able to take advantage of *Connex* fragmentation. This means that your batch size, including RTPS protocol overhead, has to be limited to the transport MTU. See [34.3 Large Data Fragmentation on page 524](#) for more information.

## 52.9 Security

Fine-grained security and access control at the *Topic* level is provided through the use of *RTI Security Plugins*, which are the *Connex* implementation of the [OMG 'DDS Security' specification, version 1.1](#), builtin plugins. For detailed information on how to secure your *Connex* system, see the *RTI Security Plugins User's Manual*.

In addition, you can use symmetric cryptography using pre-shared keys to protect the integrity of the Binding Ping messages (see [52.10.2 Binding Ping Messages on page 1034](#)) and the communication with *Cloud Discovery Service*. For further details, see the "Support for RTI Real-Time WAN Transport" chapter in the *RTI Security Plugins User's Manual*.

## 52.10 Advanced Concepts

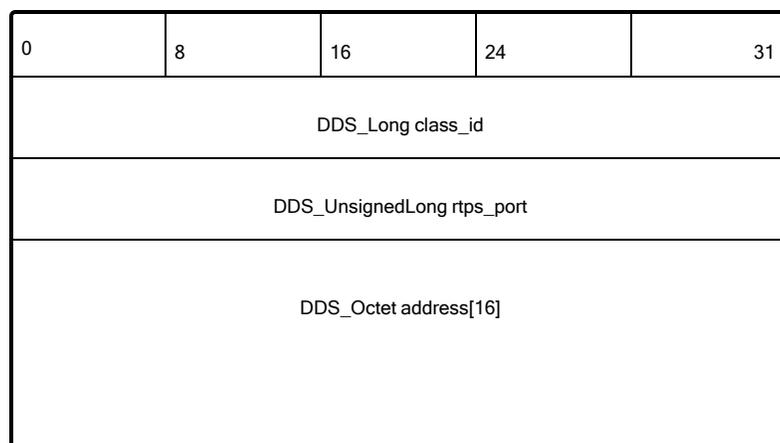

### 52.10.1 Transport Locators

This section provides information about the format of the locators associated with the *Real-Time WAN Transport*. For general information about RTPS locators, see [Chapter 26 Discovered RTPS Locators and Changes with IP Mobility on page 348](#).

An RTPS locator is an address at which a DDS endpoint (*DataWriter* or *DataReader*) can be reached. Default locators for discovery endpoints and user data endpoints are exchanged with the Participant Announcement (PA).

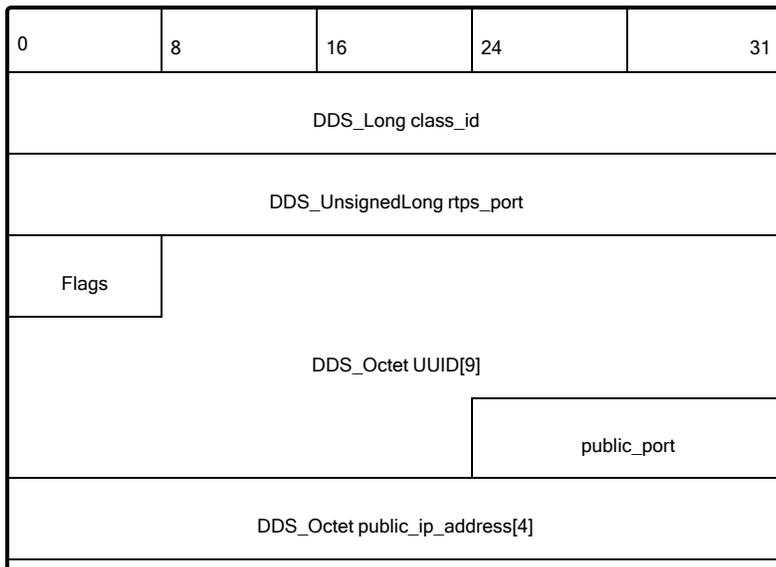

An RTPS locator consists of a transport Class ID, an address of 128 bits, and a logical port called the RTPS port, as shown in [Figure 52.16: RTPS Locator below](#).

**Figure 52.16: RTPS Locator**

The locators for *Real-Time WAN Transport* use the following mapping:

Figure 52.17: RTPS WAN Locator

**Flags** has the following format: x|x|x|x|x|B|P|U

The B flag indicates whether the locator is unidirectional or bidirectional. Bidirectional locators can send/receive RTPS traffic. Unidirectional locators can only receive RTPS traffic. If the B flag is set, the P flag must be set, too. Locators with the B flag set are called **BIDIRECTIONAL** locators.

The P flag indicates that the locator contains a public IP address and public port where a DDS endpoint can be reached. **public\_ip\_address** contains the public IP address, and **public\_port** contains the public UDP port. The public UDP port is always used to receive data, and, if the B flag is set, it is also used to send data. Locators with the P flag set are called **PUBLIC** locators.

The U flag indicates whether the locator contains a UUID. While this identifier by itself cannot be directly used to reach a DDS endpoint in a *DomainParticipant* DP1, the UUID can be mapped to a public address by *Cloud Discovery Service* and other *DomainParticipants*. Also, a locator can have both the U flag and the P flag, enabled simultaneously. Locators with the U flag set are called **UUID** locators.

A **PUBLIC+UUID locator** is a locator in which both the U flag and P flag are set.

Initial peers locators will have the B and P flags set and the U flag unset.

The U flag will be set for locators generated automatically by a *DomainParticipant*.

The P flag will be automatically set for locators generated for a transport that is configured using the property **dds.transport.UDPv4\_WAN.builtin.public\_address**. The flag will be also be set by *Cloud Discovery Service* when generating locators that contain the service reflexive address for a UUID locator.

## 52.10.2 Binding Ping Messages

As described in [52.8.1 Setting Real-Time WAN Transport Properties on page 1016](#), *Real-Time WAN Transport* uses special RTPS messages called Binding Ping messages to open NAT bindings and to resolve UUID locators into public IP transport addresses.

Binding Ping messages contain the UUID and the RTPS port of the locator with which they are associated. This information allows the receiving *Real-Time WAN Transport* to create and update the mapping between a (UUID, RTPS port) pair and its corresponding public address. [Figure 52.18: BINDING\\_PING messages below](#) depicts the structure of a Binding Ping message.

**Figure 52.18: BINDING\_PING messages**

0	7	15	31
BINDING_PING	X X X X X B L E	octetsToNextHeader	
DDS_UnsignedLong rtps_port			
DDS_Octet address[12] [If L=0]			
DDS_Octet address[16] [If L=1]			

The security of the Binding Pings can be configured using the `com.rti.serv.secure.cryptography.rtps_protection_key` property. For further details, see the "Support for RTI Real-Time WAN Transport" chapter in the *RTI Security Plugins User's Manual*.

## 52.10.3 Communication Establishment Protocol for Peer-to-Peer Communication with Participants behind Cone NATs

This section describes the communication establishment protocol for the scenario described in [52.4.2 Peer-to-Peer Communication between Two Internal Participants on page 998](#).

Communication is established as indicated in [Figure 52.19: Public Address Resolution Phase Using Cloud Discovery Service \(CDS\) on the next page](#) and [Figure 52.20: UDP Hole Punching Phase on page 1036](#).

Figure 52.19: Public Address Resolution Phase Using Cloud Discovery Service (CDS)

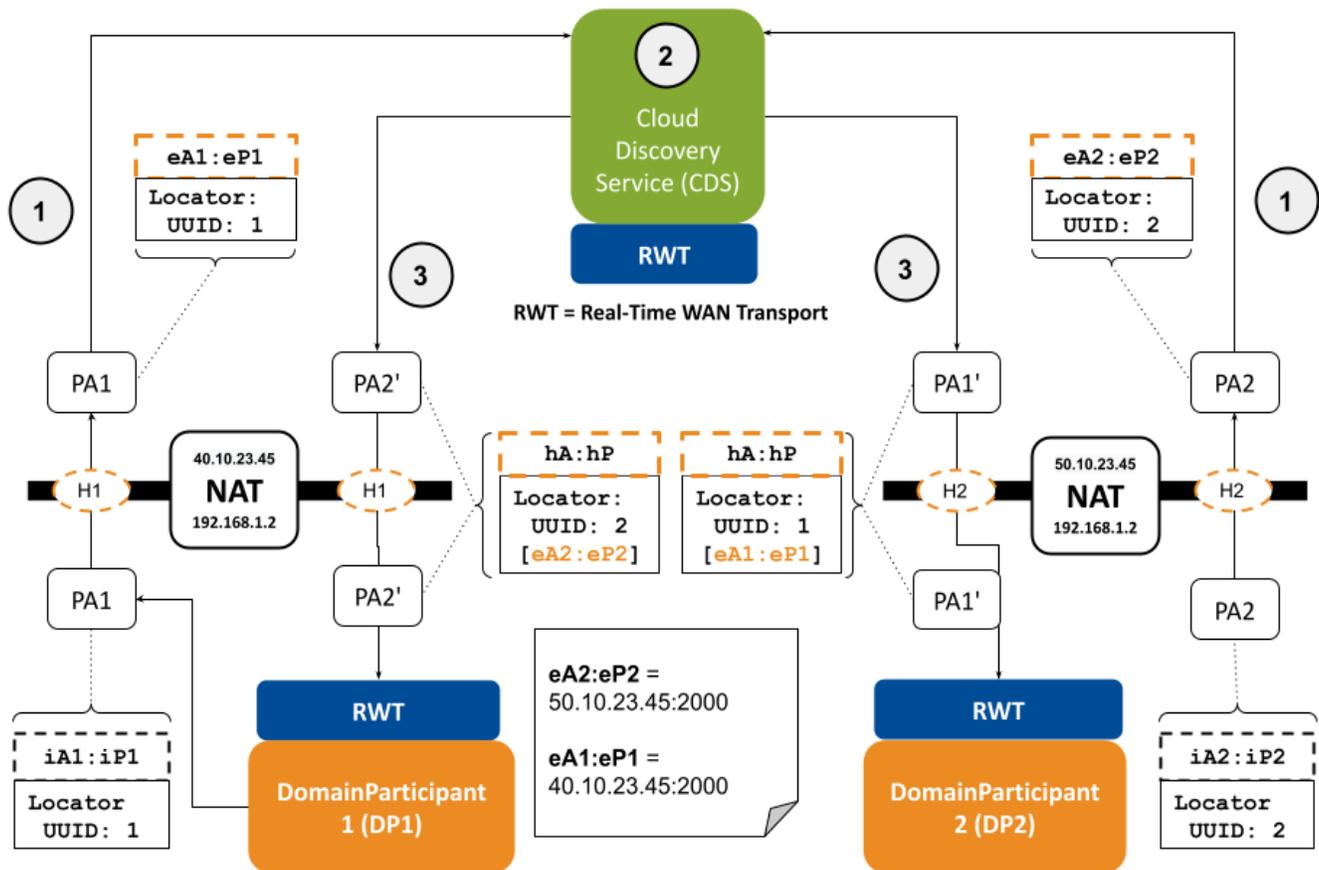

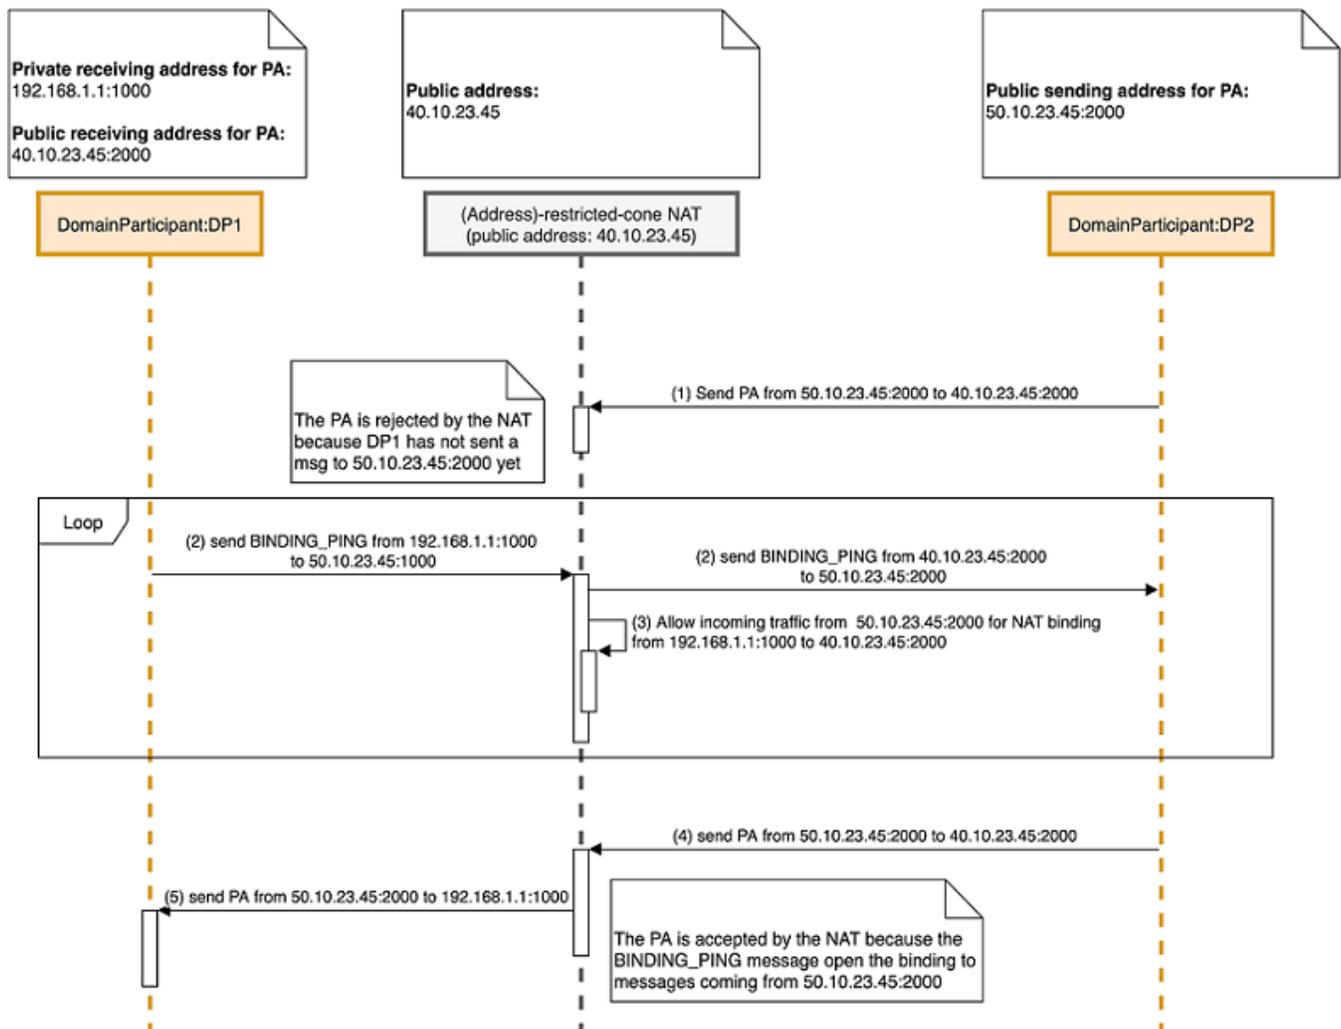

Figure 52.20: UDP Hole Punching Phase on the next page illustrates how UDP hole punching works to allow sending PAs (PA1 and PA2) from DP2 data to DP1. For simplicity, the restricted-cone NAT for DP2 has been removed from the sequence diagram.

Figure 52.20: UDP Hole Punching Phase

In the initial state, DP2 has received a PUBLIC+UUID locator from *Cloud Discovery Service* indicating that DP1 can be reached at the address 40.10.23.45:2000. The PUBLIC+UUID locator was part of PA1' in [Figure 52.19: Public Address Resolution Phase Using Cloud Discovery Service \(CDS\) on the previous page](#).

1. When DP2 tries to send a PA to DP1, the NAT router for DP1 will drop the message because the NAT binding from 192.168.1.1:100 to 40.10.23.45:2000 does not allow incoming traffic from 50.10.23.445:2000 (see [52.3.2 NAT Kinds on page 989](#) for additional details).
2. To allow incoming traffic from DP2, DP1 sends an RTPS BINDING\_PING message to DP2 public address 50.10.23.445:2000.
3. After the BINDING\_PING is sent, the NAT router for DP1 will allow PA traffic from DP2 through the NAT binding from 192.168.1.1:100 to 40.10.23.45:2000. For additional details on the BINDING\_PING message see [52.10.2 Binding Ping Messages on page 1034](#).

4. and 5) The next PA announcement coming from DP2 to DP1 will make it through the NAT router for DP1.

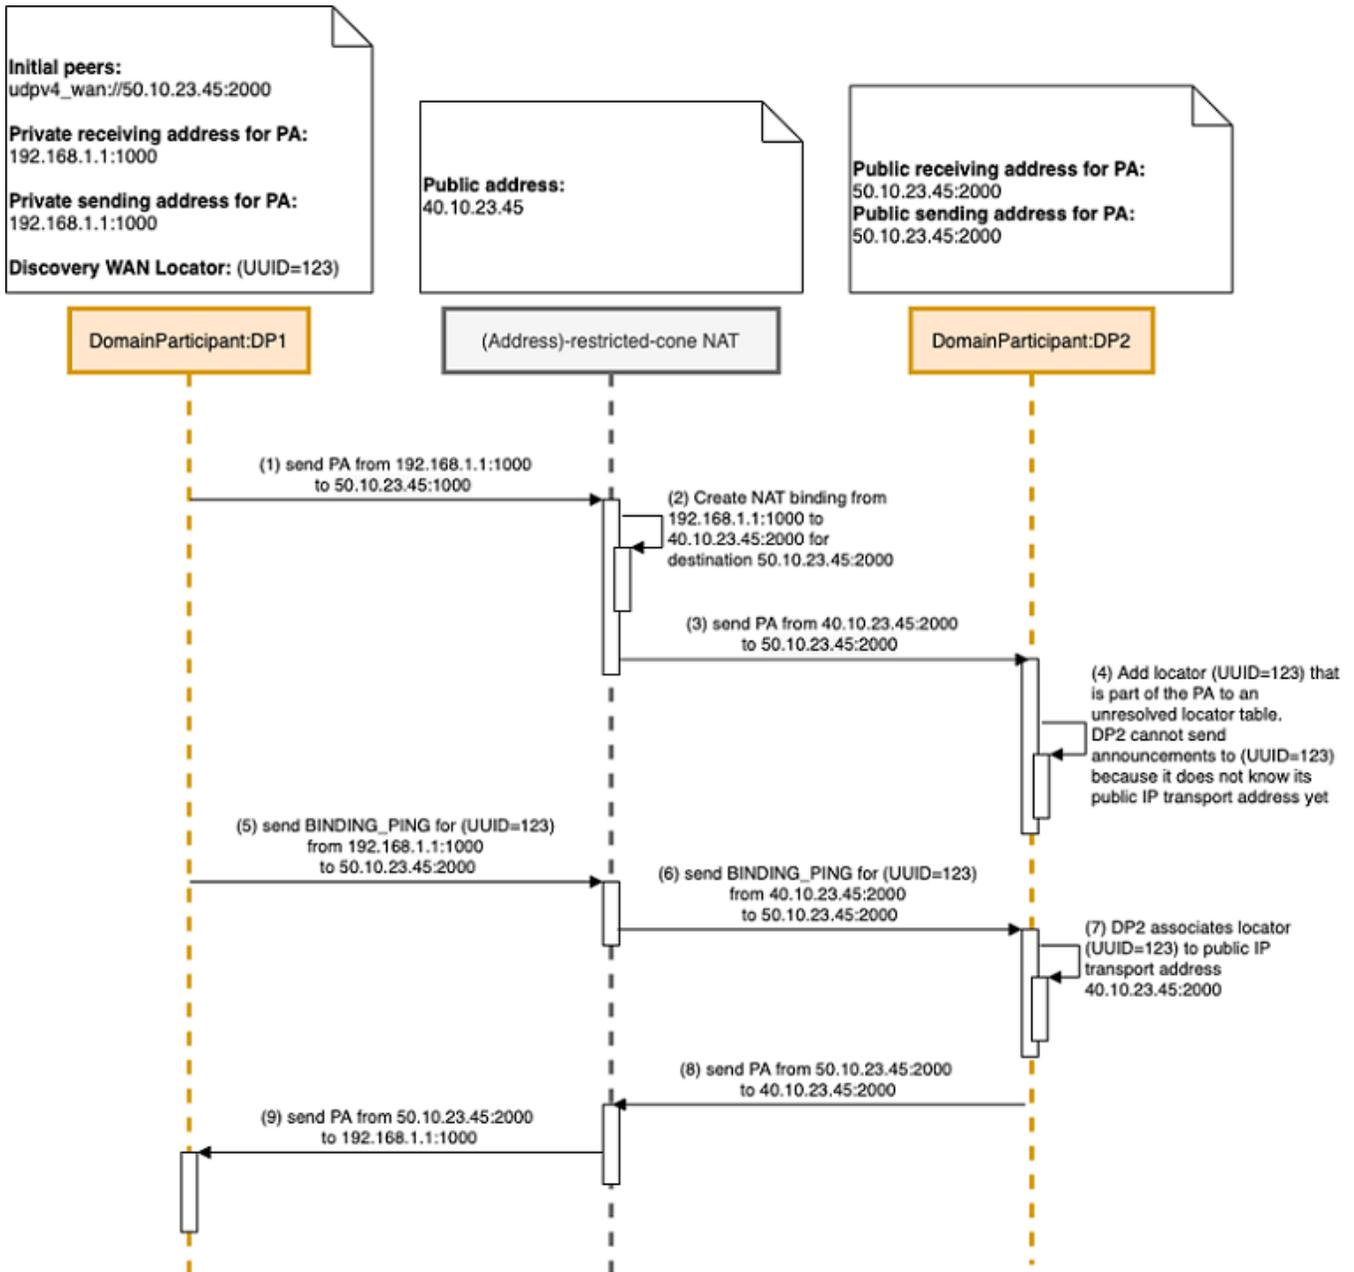

The same UDP hole punching mechanism is also used in the opposite direction so that DP1 can send PAs to DP2.

### **52.10.4 Communication Establishment Protocol for Peer-to-Peer Communication with a Participant that has a Public Address**

This section describes the communication establishment protocol for the scenario described in [52.4.1 Peer-to-Peer Communication between Internal Participant and External Participant on page 995](#).

Communication is established using a technique called “Connection Reversal” as described in [Figure 52.21: Connection Reversal Protocol on the next page](#).

Figure 52.21: Connection Reversal Protocol

1. DP1 sends a PA to DP2 by using the public IP transport address contained in DP1's initial peers (50.10.23.45:2000).
2. The PA creates a NAT binding in the DP1 NAT router from 192.168.1.1:100 to 40.10.23.45:2000 for the destination address 50.10.23.45:2000.
3. The NAT router sends the PA from DP1 to DP2 by replacing the source IP transport address with 40.10.23.45:2000.

4. When DP2 receives the PA from DP1, it will add the discovery UUID locator for DP1 contained in the PA to an unresolved locator table. DP1 cannot send PAs to DP2 yet because it does not know the public IP transport address corresponding to the discovery UUID locator for DP1.
5. DP1 sends a BINDING\_PING message from the address associated with the discovery UUID locator to the initial peer for DP2. The initial peer contains the address from which DP2 will send PAs.
6. Explained in 5).
7. When DP2 receives the BINDING\_PING from DP1, it extracts the source IP transport address (40.10.23.45:2000) from the UDP packet containing the BINDING\_PING and associates this address to the unresolved discovery UUID locator from DP1.
8. and 9) At this point, DP2 can send a PA to DP1.

## 52.11 Transport Debugging

It is recommended that you read [52.10 Advanced Concepts on page 1032](#) before proceeding with this section.

The *Real-Time WAN Transport* operation can be debugged by setting the *Connex* verbosity to LOCAL for the COMMUNICATION category:

```
<participant_factory_qos>
  <logging>
    <category>COMMUNICATION</category>
    <verbosity>LOCAL</verbosity>
  </logging>
</participant_factory_qos>
```

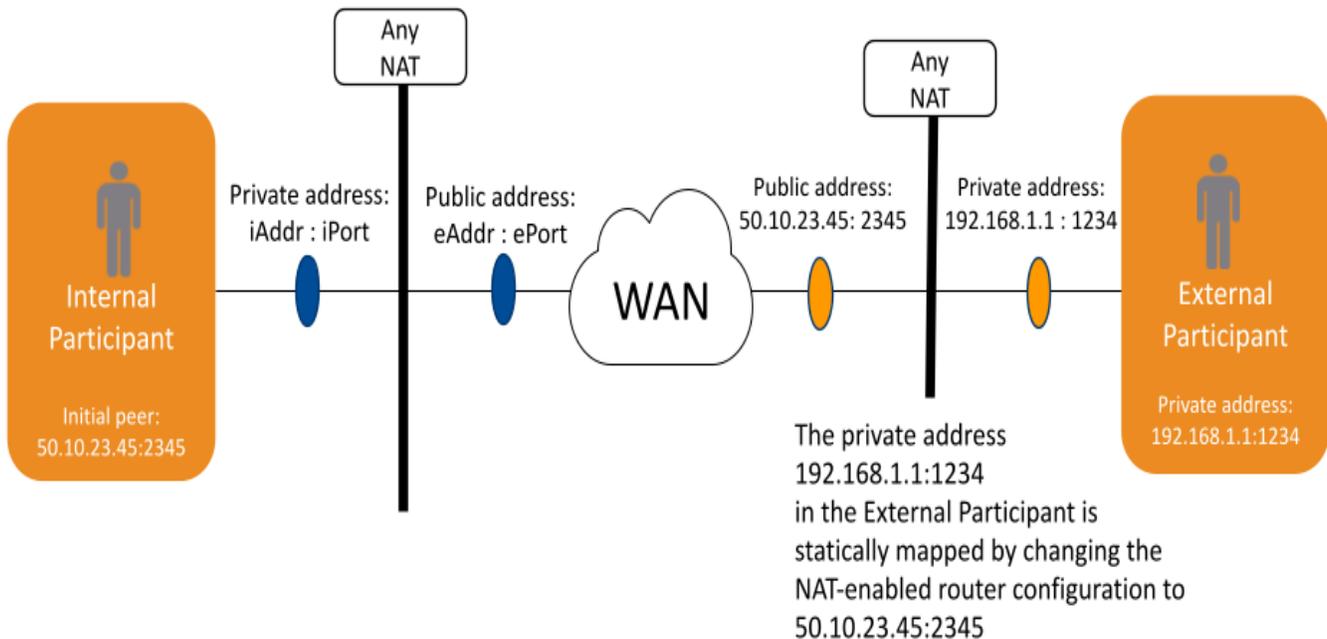

Or programmatically, shown here in modern C++ (other languages are similar):

```
Logger::instance().verbosity_by_category(LogCategory::COMMUNICATION, Verbosity::STATUS_
LOCAL);
```

### 52.11.1 Debugging Peer-to-Peer Communication with a Participant that has a Public Address

Consider the communication scenario described in [52.4.1 Peer-to-Peer Communication between Internal Participant and External Participant on page 995](#). Let's assume the External Participant creates a *DataReader* on a *Topic* 'Example' and the Internal Participant a *DataWriter* on the same *Topic* 'Example'.

Figure 52.22: Peer-to-Peer with Any-NAT with a Public Participant

After enabling logging verbosity as indicated above, we can follow the *Real-Time WAN Transport* life-cycle by looking at the logging output:

1. When the Internal Participant is started, it creates a send resource for the locator provided in the initial peers 50.10.23.45:2345:

```
[0x01015FAF,0xBA456FDC,0x040952B8:0x000001C1{Domain=0}|CREATE DP|ENABLE]
NDDS_Transport_UDP_create_sendresource_srEA:Created send resource for
f=BP,u={00,00,00,00,00,00,00,00,00,00},p=50.10.23.45:2345:7410
```

A send resource is a transport object that can be used to send data to a locator.

We know this is the initial peer locator because:

- The locator UUID is all zeros: `u={00,00,00,00,00,00,00,00,00,00}`.
- The public address is the one provided in the initial peers: 50.10.23.45:2345.

7410 is the RTPS port for discovery data on domain 0. To see how RTPS ports are calculated, see [44.9.2 Ports Used for Discovery on page 732](#).

At this point, the Internal Participant starts sending PAs to the External Participant.

2. When the External Participant receives the PA from the Internal Participant, it creates a send resource for the discovery UUID locator contained in the PA.

```
[0x01017AA5,0x4B4691C4,0x600386AD:0x000100C7{Entity=DR,MessageKind=DATA}|RECEIVE FROM
0x00000000,0x00000000,0x00000000:0x000100C2]
NDDS_Transport_UDP_create_sendresource_srEA:Created send resource for
f=U,u={47,82,BA,ED,A3,27,6F,A8,42},p=172.31.11.80:0:7410
```

The UUID locator is a non-reachable locator.

- f=U indicates that this is a non-reachable UUID locator.
- u={47,82,BA,ED,A3,27,6F,A8,42} is the UUID of the discovery locator coming from the Internal Participant.
- Even though the public address field has the value (p=172.31.11.80:0:7410), the IP address in the log message is not reachable and it corresponds to the private IP address of the Internal Participant.

The External Participant also creates a send resource for the user data UUID locator contained in the PA once it discovers the *DataWriter* created by the Internal Participant. The user data locator will be used to send RTPS traffic for *Topic* ‘Example’.

```
[0x01017AA5,0x4B4691C4,0x600386AD:0x80000004{Entity=DR,Topic=Example
Quote,Type=Quote,Domain=0}|LINK
0x01010402,0x1CA21E93,0xB02F44C3:0x80000003{Type=Quote}]
NDDS_Transport_UDP_create_sendresource_srEA:Created send resource for
f=U,u={47,82,BA,ED,A3,27,6F,A8,42},p=172.31.11.80:0:7411
```

The distinction between discovery and user data locators is based on the RTPS port. 7410 is discovery and 7411 is user data.

3. The External Participant cannot send a PA to the Internal Participant until it resolves the public address for the locator with UUID {47,82,BA,ED,A3,27,6F,A8,42} and the RTPS port 7410 associated with the discovery send resource created in step 2.

The public address resolution is done when a BINDING\_PING is received from the Internal Participant.

```
[0x01017AA5,0x4B4691C4,0x600386AD:0x000001C1|PROCESS BINDING PING]
NDDS_Transport_UDPv4_WAN_PublicAddressMappingInfo_log:added
P=7410,u={47,82,BA,ED,A3,27,6F,A8,42},k=3,p=54.151.6.102:7535,f=BPU,r=0
```

- P=7410 is the RTPS port.
- u={47,82,BA,ED,A3,27,6F,A8,42} is the UUID of the locator coming from the Internal Participant.
- f=BPU indicates that the resolved locator is a PUBLIC+UUID locator that can be used for bidirectional communication. This means that the Internal Participant will be sending RTPS messages using the address 54.151.6.102:7535.
- k=3 and r=0 are internal fields not relevant for this discussion.

The External Participant also will not be able to send RTPS data for *Topic* ‘T’ until it resolves the public address for the locator identified by the UUID {47,82,BA,ED,A3,27,6F,A8,42} and the RTPS port 7411. This resolution is also done by the reception of a BINDING\_PING:

```
[0x01017AA5,0x4B4691C4,0x600386AD:0x000001C1|PROCESS_BINDING_PING]
NDDS_Transport_UDPv4_WAN_PublicAddressMappingInfo_log:added
P=7411,u={47,82,BA,ED,A3,27,6F,A8,42},k=3,p=54.151.6.102:7536,f=PU,r=0
```

4. The Internal Participant receives a PA from the External Participant, and it creates two transport send resources: one for sending discovery data and one for sending user data:

Discovery data:

```
[0x01010402,0x1CA21E93,0xB02F44C3:0x000100C7{Entity=DR,MessageKind=DATA}|RECEIVE_FROM
0x00000000,0x00000000,0x00000000:0x000100C2]
NDDS_Transport_UDP_create_sendresource_srEA:Created send resource for
f=BPU,u={F2,7D,8B,5D,90,AF,93,DD,90},p=50.10.23.45:2345:7410
```

User data:

```
[0x01010402,0x1CA21E93,0xB02F44C3:0x80000003{Entity=DW,Topic=Example
Quote,Type=Quote,Domain=0}|LINK
0x01017AA5,0x4B4691C4,0x600386AD:0x80000004{Type=Quote}]
NDDS_Transport_UDP_create_sendresource_srEA:Created send resource for
f=BPU,u={F2,7D,8B,5D,90,AF,93,DD,90},p=50.10.23.45:2345:7411
```

The user data locator will be used to send RTPS traffic for *Topic* ‘Example’.

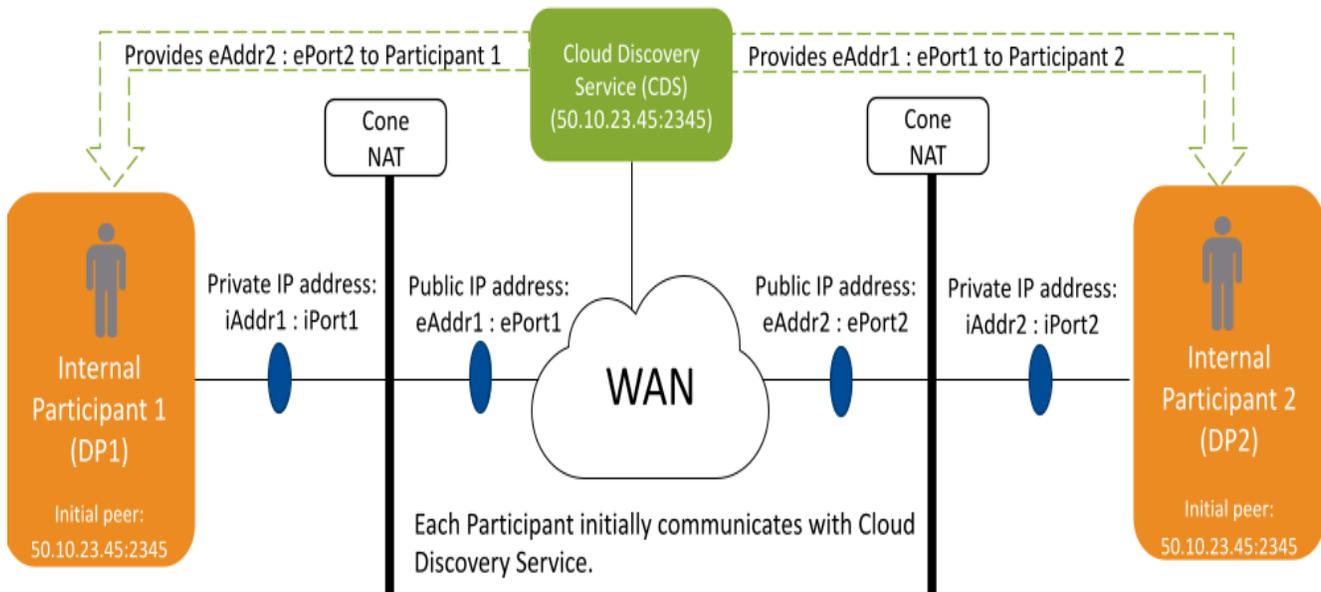

Note that the public address 50.10.23.45:2345 is the same for both send resources because we are configuring the External Participant to use a single UDP port for communications. The distinction between user data and discovery data is done by looking at the RTPS port. 7410 is the port for discovery and 7411 is the port for user data.

5. At this point, both Participants can communicate with each other. The External Participant will start receiving samples for *Topic* ‘Example’ from the Internal Participant.

## 52.11.2 Peer-to-Peer Communication with Participants behind Cone NATs

This section covers the scenario described in [52.4.2 Peer-to-Peer Communication between Two Internal Participants on page 998](#). It is recommended that you read that section to interpret some of the log messages.

Figure 52.23: Peer-to-Peer with Cone NATs

Cloud Discovery Service also serves as a directory, so that a participant only needs to know about the CDS to connect to multiple peers automatically.

The Internal Participant 1 (DP1) will create a *DataWriter* publishing data on a *Topic* 'T', and the Internal Participant 2 (DP2) will create a *DataReader* subscribing to *Topic* 'T'.

This section will focus on debugging the *Real-Time WAN Transport* lifecycle for DP1 and DP2. For details on how to debug *Cloud Discovery Service* (CDS), see "Debugging Cloud Discovery Service with the UDP WAN Transport," in the *NAT Traversal* section of the *RTI Cloud Discovery Service* documentation .

1. When DP1 is started, it creates a send resource for the locator provided as the initial peer 50.10.23.45:2345. This locator corresponds to the CDS locator.

```
[0x01016F1B,0x2294D448,0x8060E06B:0x000001C1{Domain=0}|CREATE DP|ENABLE]
NDDS_Transport_UDP_create_sendresource_srEA:Created send resource for
f=BP,u={00,00,00,00,00,00,00,00,00,00},p=50.10.23.45:2345:2345
```

We know this is the initial peer locator because:

- The locator UUID is all zeros: `u={00,00,00,00,00,00,00,00,00,00}`.
- The public address is the one provided in the initial peers: 50.10.23.45:2345.

At this point the DP1 starts sending PAs to CDS.

- Likewise, when DP2 is started, it creates a send resource for the CDS locator provided as the initial peer 50.10.23.45:2345.

```
[0x01017116,0xF14A169C,0xE7799A94:0x000001C1{Domain=0}|CREATE_DP|ENABLE]
NDDS_Transport_UDP_create_sendresource_srEA:Created send resource for
f=BP,u={00,00,00,00,00,00,00,00,00},p=50.10.23.45:2345:2345
```

At this point, DP2 starts sending PAs to CDS.

- To start sending PAs to DP2, DP1 must receive a PA from CDS on behalf of DP2 containing the discovery UUID+PUBLIC locator at which DP2 can be reached.
- Once DP1 receives the PA from CDS, it creates a send resource for the discovery UUID+PUBLIC locator used for discovery and starts sending PAs to DP2.

```
[0x01016F1B,0x2294D448,0x8060E06B:0x000100C7{Entity=DR,MessageKind=DATA}|RECEIVE_FROM
0x00000000,0x00000000,0x00000000:0x000100C2]
NDDS_Transport_UDP_create_sendresource_srEA:Created send resource for
f=BPU,u={50,26,6D,EA,B7,11,AC,B9,5F},p=99.35.17.233:7535:7410
```

99.35.17.233:7535 is the public address at which DP2 will receive RTPS discovery traffic.

- To start sending PAs to DP1, DP2 must receive a PA from CDS on behalf of DP1 containing the discovery UUID+PUBLIC locator at which DP1 can be reached.
- Once DP2 receives the PA from CDS, it creates a send resource for the UUID+PUBLIC locator used for discovery and starts sending PAs to DP1.

```
[0x01017116,0xF14A169C,0xE7799A94:0x000100C7{Entity=DR,MessageKind=DATA}|RECEIVE_FROM
0x00000000,0x00000000,0x00000000:0x000100C2]
NDDS_Transport_UDP_create_sendresource_srEA:Created send resource for
f=BPU,u={B1,1D,4B,B5,A1,58,5E,E1,58},p=54.151.6.102:7535:7410
```

54.151.6.102:7535 is the public address at which DP 1 will receive RTPS discovery traffic.

- After DP1 discovers DP2's *DataReader* for *Topic* 'T', DP1 will create a send resource to send RTPS data for *Topic* 'T' (samples, GAPS, and HBs) to the *DataReader* in DP2.

```
[0x01016F1B,0x2294D448,0x8060E06B:0x80000003{Entity=DW,Topic=Example
Quote,Type=Quote,Domain=0}|LINK
0x01017116,0xF14A169C,0xE7799A94:0x80000004{C=Quote}]
NDDS_Transport_UDP_create_sendresource_srEA:Created send resource for
f=PU,u={50,26,6D,EA,B7,11,AC,B9,5F},p=99.35.17.233:7536:7411
```

99.35.17.233:7536 is the public address at which DP1 will receive RTPS user data traffic for *Topic* 'T'.

- After DP2 discovers DP1's *DataWriter* for *Topic* 'T', DP2 will create a send resource to send RTPS data for *Topic* 'T' (NACKs) to the *DataWriter* in DP1.

```
[0x01017116,0xF14A169C,0xE7799A94:0x80000004{Entity=DR,Topic=Example
Quote,Type=Quote,Domain=0}|LINK
0x01016F1B,0x2294D448,0x8060E06B:0x80000003{Type=Quote}]
NDDS_Transport_UDP_create_sendresource_srEA:Created send resource for
f=U,u={B1,1D,4B,B5,A1,58,5E,E1,58},p=172.31.11.80:0:7411
```

Note that in this case, the send resource has been created with a UUID locator that is not reachable. When this occurs, the public IP transport address for the UUID locator will be resolved by receiving a `BINDING_PING` from DP1.

```
[0x01017116,0xF14A169C,0xE7799A94:0x80000004{Entity=DR,Topic=Example
Quote,Type=Quote,Domain=0}|MODIFY
LINK 0x01016F1B,0x2294D448,0x8060E06B:0x80000003{Type=Quote}]
NDDS_Transport_UDPv4_WAN_PublicAddressMappingInfo_log:updated
P=7411,u={B1,1D,4B,B5,A1,58,5E,E1,58},k=1,p=54.151.6.102:7536,f=PU,r=1
```

- At this point, both Participants can communicate with each other. DP2's *DataReader* will start receiving samples for *Topic* 'Example' from DP1's *DataWriter*.

## 52.12 Tools Integration

RTI Tools such as *RTI Admin Console* can use *Real-Time WAN Transport* if they are configured appropriately.

*Admin Console* ships with a builtin profile that enables use of the *Real-Time WAN Transport*:

**AdminConsole::RealTimeWAN**. Make sure you select that profile in the *Admin Console* Preferences and provide the right initial peers (see [52.7 Transport Initial Peers on page 1014](#)) to *Admin Console* to inspect *Connnext* applications running across the WAN. See [Figure 52.24: Real-Time WAN Transport and Admin Console on the next page](#).

```
<qos_library name="AdminConsole">
  <qos_profile name="RealTimeWAN" base_name="AdminConsole::Default">
    <domain_participant_qos>
      <transport_builtin>
        <mask>MASK_DEFAULT|UDPv4_WAN</mask>
      </transport_builtin>
    </domain_participant_qos>
  </qos_profile>
</qos_library>
```

**Important:** The auto-join feature will not work when using *Real-Time WAN Transport* because multicast is not available in WAN environments. You will have to join the WAN domain(s) explicitly.

Figure 52.24: *Real-Time WAN Transport and Admin Console*

The screenshot displays the Administration console for Real-Time WAN Transport. The interface includes several sections:

- Cleanup Not Present Entities:** A dropdown menu showing "The period (in seconds) to automatically cleanup" set to 30.
- Graph visualization options:** A dropdown menu showing "Connection nodes to show on graph startup" set to 5.
- Domains:** A section explaining that distributed systems can be divided into domains and that specific communication characteristics called Quality of Service (QoS) can be specified for each domain.
- QoS Profile Selection:** A dropdown menu showing "AdminConsole::Default (default)" selected. A red box highlights this dropdown, and a red line points to the text "Select AdminConsole::RealTimeWAN".
- Discovery Peers:** A text input field with a pencil icon. A red box highlights the pencil icon, and a red line points to the text "Enter initial peers".
- Domain Management:** Two radio buttons: "Automatically discover and join domains" (unselected) and "Manually join and leave domains" (selected). A red box highlights the selected radio button, and a red line points to the text "Manually join/leave".
- Files specifying QoS profiles:** A text input field with "Add File(s)..." and "Remove File(s)" buttons.

At the bottom of the console, there are "Apply and Close" and "Cancel" buttons.

## 52.13 Troubleshooting Real-Time WAN Transport

### 52.13.1 Communication Stops Working after Application Transitions to Different Network

**Possible Root Cause:**

If you are using *Cloud Discovery Service*, it is possible that before the network transition, all the applications were behind cone NATs. When the transition occurs, the application that is changing to a new network connects to a symmetric NAT.

This configuration is not currently supported. Symmetric NATs are only supported in scenarios like the one described in [Figure 52.7: Peer-to-Peer between a Participant behind Any Kind of NAT and an External Participant on page 996](#).

To validate if you are behind a symmetric NAT in the new network, you can run the application *natat* as described in [52.3.3 Identifying the NAT Type on page 991](#).

### Solution:

When you do not know in advance whether the networks in which applications run are behind cone NATs or symmetric NATs, you may want to do a relay deployment as indicated in [52.5.2 Relayed Edge-to-Edge Deployment Scenario on page 1006](#).

## 52.13.2 Communication not Established after Changing Cloud Discovery Service <receiver\_port>

For example, when changing the *Cloud Discovery Service* configuration from:

```
<dds>
  <cloud_discovery_service name="CDS">
    <transport>
      <element>
        <alias>builtin.udpv4_wan</alias>
        <receive_port>2345</receive_port>
        <property>
          <element>
            <name>dds.transport.UDPv4_WAN.builtin.public_address</name>
            <value>50.10.23.45</value>
          </element>
        </property>
      </element>
    </transport>
  </cloud_discovery_service>
</dds>
```

To:

```
<dds>
  <cloud_discovery_service name="CDS">
    <transport>
      <element>
        <alias>builtin.udpv4_wan</alias>
        <receive_port>6001</receive_port>
        <property>
          <element>
            <name>dds.transport.UDPv4_WAN.builtin.public_address</name>
            <value>50.10.23.45</value>
          </element>
        </property>
      </element>
    </transport>
  </cloud_discovery_service>
</dds>
```

```

        </element>
      </property>
    </element>
  </transport>
</cloud_discovery_service>
</dds>

```

**Possible Root Cause:**

If *Cloud Discovery Service* (CDS) is running behind a NAT-enabled router, it is possible that you have not created a static NAT binding in the router for the new public address: 50.10.23.45:6001.

**Solution:**

Create a new static NAT binding to support the port change. The NAT binding must create this mapping:

$$\begin{aligned} \text{<CDS private address X>:<port number Y>} &\rightarrow \text{<new public address Z>:<port number Y>} \\ \text{<CDS private address>:6001} &\rightarrow 50.10.23.45:6001 \end{aligned}$$

Note that the private host CDS port and public port must be the same (6001 is the port number for both in the example above). To make them different, use the transport property `dds.transport.UDPv4_WAN.builtin.comm_ports`. See [52.8.1 Setting Real-Time WAN Transport Properties on page 1016](#).

## 52.13.3 Communication not Established even though Transport Settings are Set Correctly

**Possible Root Cause:**

There may be an IP fragmentation problem. For WAN communications, it is not a good idea to rely on IP fragmentation. IP fragmentation causes significant issues in UDP, where there is no support for an MTU (maximum transmission unit) discovery protocol as there is in TCP. These are some of the problems associated with IP fragmentation:

- To successfully reassemble a packet, all fragments must be delivered. No fragment can become corrupt or get lost in-flight. If a fragment is lost, the whole packet will be lost.
- Before reassembly, a host must hold partial, fragment datagrams in memory. This opens an opportunity for memory exhaustion attacks.
- Subsequent fragments lack the higher-layer header. The TCP or UDP header is only present in the first fragment, making it impossible for firewalls to filter fragment datagrams based on criteria like source or destination ports.

When testing over some cellular networks, in some cases you may not be able to send samples larger than the IP MTU, such as images, without losing a large percentage of the frames.

**Solution:**

Disable IP fragmentation by letting *Connex* do fragmentation at the RTPS level. For details, see section [52.8.3 Disabling IP Fragmentation for Real-Time WAN Transport on page 1030](#).

## 52.13.4 Slow Discovery using Cloud Discovery Service

### Possible Root Cause:

If you are using *Cloud Discovery Service*, it is possible that the Participant Announcements sent by *Cloud Discovery Service* to other *DomainParticipants* are lost when discovering a new *DomainParticipant* or when there are changes in the configuration of a *DomainParticipant*. This may delay the discovery process in lossy network environments.

### Solution:

You can increase the number of times that a Participant Announcement from a new *DomainParticipant* is forwarded by *Cloud Discovery Service* to other *DomainParticipants*. The default is 5 times.

You can also adjust the frequency at which the Participant Announcements are forwarded to the other *DomainParticipants*. The default is 1 second.

For example:

```
<dds>
  <cloud_discovery_service name="CDS">
    <transport>
      <element>
        <alias>builtin.udpv4_wan</alias>
        <receive_port>2345</receive_port>
        <property>
          <element>
            <name>dds.transport.UDPv4_WAN.builtin.public_address</name>
            <value>60.10.23.45</value>
          </element>
        </property>
      </element>
    </transport>
    <forwarder>
      <event>
        <!-- Set to a high value of 10 for lossy networks -->
        <new_or_change_participant_announcements>
          10
        </new_or_change_participant_announcements>
        <min_new_or_change_participant_announcements_period>
          <sec>1</sec>
          <nanosec>0</nanosec>
        </min_new_or_change_participant_announcements_period>
        <!-- Increase the spacing between resend event samples -->
        <max_new_or_change_participant_announcements_period>
          <sec>2</sec>
          <nanosec>0</nanosec>
        </max_new_or_change_participant_announcements_period>
      </event>
    </forwarder>
  </cloud_discovery_service>
</dds>
```

```
        </event>
    </forwarder>
</cloud_discovery_service>
</dds>
```

For additional information, see "XML Tags for Configuring RTI Cloud Discovery Service," in the *Configuration* section of the *RTI Cloud Discovery Service* documentation.

# Chapter 53 RTI TCP Transport

*RTI TCP Transport* is only available on specific architectures. See the [RTI Connex Core Libraries Platform Notes](#) for details.

Out of the box, *Connex* uses the UDPv4 and Shared Memory transport to communicate with other DDS applications. This configuration is appropriate for systems running within a single LAN. However, using UDPv4 introduces some problems when *Connex* applications in different LANs need to communicate:

- UDPv4 traffic is usually filtered out by the LAN firewalls for security reasons.
- Forwarded ports are usually TCP ports.
- Each LAN may run in its own private IP address space and use NAT (Network Address Translation) to communicate with other networks.

*TCP Transport* enables participant discovery and data exchange using the TCP protocol (either on a local LAN, or over the public WAN). *TCP Transport* allows *Connex* to address the challenges of using TCP as a low-level communication mechanism between peers and limits the number of ports exposed to one. (When using the default UDP transport, a *Connex* application uses multiple UDP ports for communication, which may make it unsuitable for deployment across firewalled networks).

## 53.1 TCP Communication Scenarios

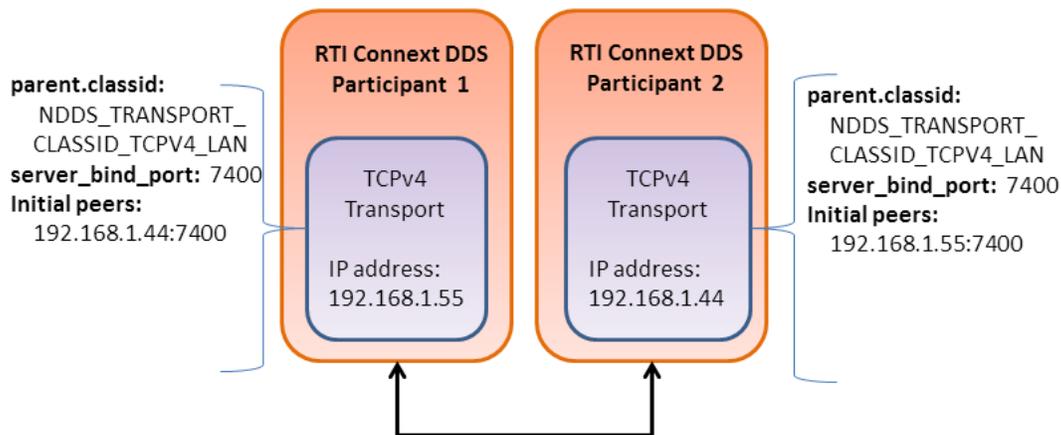

*TCP Transport* can be used to address multiple communication scenarios—from simple communication within a single LAN, to complex communication scenarios across LANs where NATs and firewalls may be involved. This section describes these scenarios:

- [53.1.1 Communication Within a Single LAN below](#)
- [53.1.2 Symmetric Communication Across NATs on the next page](#)
- [53.1.3 Asymmetric Communication Across NATs on page 1053](#)

### 53.1.1 Communication Within a Single LAN

*TCP Transport* can be used as an alternative to UDPv4 to communicate with *Connex* applications running inside the same LAN. [Figure 53.1: Communication within a Single LAN on the next page](#) shows how to configure the TCP transport in this scenario.

Figure 53.1: Communication within a Single LAN

- [parent.classid on page 1067](#) and [server\\_bind\\_port on page 1072](#) are transport properties configured using the PropertyQosPolicy of the participant. (Note: When the TCP transport is instantiated, by default it is configured to work in a LAN environment using symmetric communication and binding to port 7400 for incoming connections.) For additional information about these properties, see [Table 53.1 Properties for NDDS\\_Transport\\_TCPv4\\_Property\\_t](#).
- Initial Peers represents the peers to which the participant will be announced to. Usually, these peers are configured using the DiscoveryQosPolicy of the participant or the environment variable NDDS\_DISCOVERY\_PEERS. For information on the format of initial peers, see [53.2.1 Choosing a Transport Mode on page 1055](#).

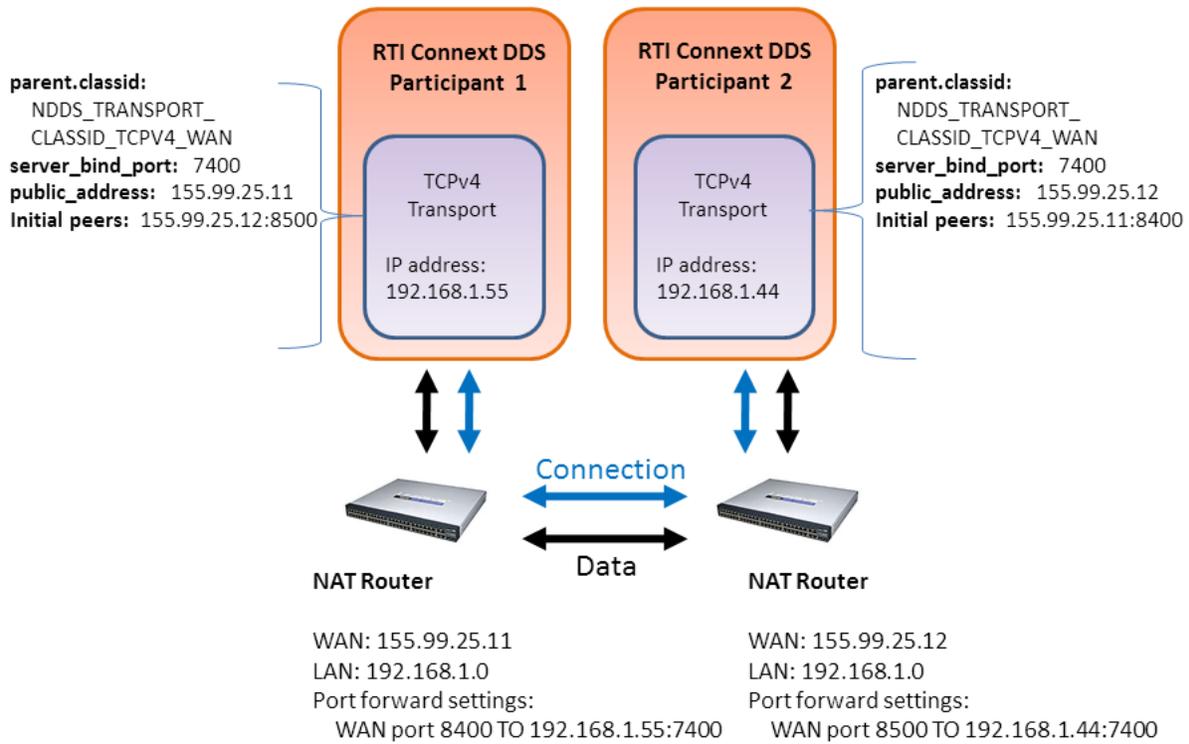

Unlike the UDPv4 transport, **you must specify the initial peers**, because multicast cannot be used with TCP.

## 53.1.2 Symmetric Communication Across NATs

In NAT communication scenarios, each one of the LANs has a private IP address space. The communication with other LANs is done through NAT routers that translate private IP addresses and ports into public IP addresses and ports.

In symmetric communication scenarios, any *Connex* application can initiate TCP connections with other applications. [Figure 53.2: Symmetric Communication Across NATs on the next page](#) shows how to configure the TCP transport in this scenario.

Figure 53.2: Symmetric Communication Across NATs

Notice that initial peers refer to the public address of the remote LAN where the *Connex* application is deployed and not the private address of the node where the application is running. In addition, the transport associated with a *Connex* instance will have to be configured with its public address ([public address on page 1071](#)) so that this information can be propagated as part of the discovery process.

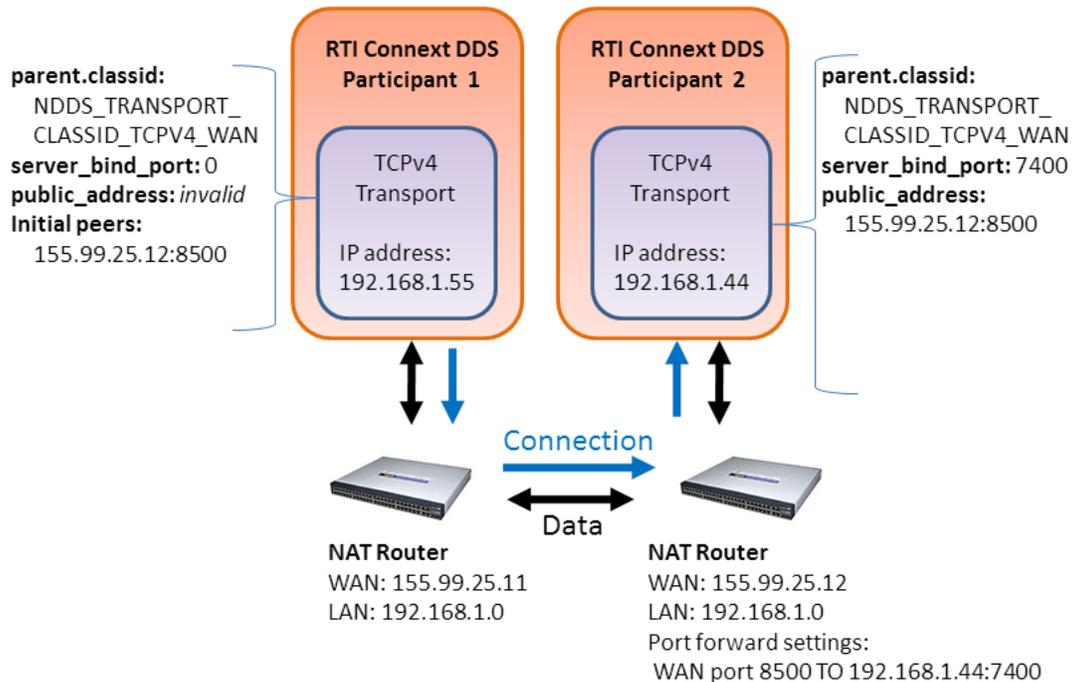

Because the public address and port of the *Connex* instances must be known before the communication is established, the NAT Routers will have to be configured statically to translate (forward) the private [server\\_bind\\_port on page 1072](#) into a public port. This process is known as static NAT or port forwarding; it allows traffic originating in outer networks to reach designated peers in the LAN behind the NAT router. You will need to refer to your router's configuration manual to understand how to correctly set up port forwarding.

### 53.1.3 Asymmetric Communication Across NATs

This scenario is similar to the previous one, except in this case the TCP connections can be initiated only by the *Connex* instance in LAN1. For security reasons, incoming connections to LAN1 are not allowed. In this case, the peer in LAN1 is considered 'unreachable.' Unreachable peers can publish and subscribe just like any other peer, but communication can occur only to a 'reachable' peer.

Figure 53.3: [Asymmetric Communication Across NATs below](#) shows how to configure the TCP transport in this scenario. Notice that the transport property `server_bind_port` is set to 0 to configure the node as unreachable.

Figure 53.3: Asymmetric Communication Across NATs

In an asymmetric configuration, an unreachable peer (that is behind a firewall or NAT without port forwarding) can still publish and subscribe like a reachable peer, but with some important limitations:

- An unreachable peer can only communicate with reachable peers: two unreachable peers cannot establish a direct communication since they are both behind a firewall and/or NAT.

Note that since *Connex* always relies on a direct connection between peers (even if there is a third node that can be reachable by both unreachable peers), **communication can never occur between unreachable peers**. For example, suppose Peers A and B are unreachable and Peer C is reachable. Communication can take place between A and C, and between B and C, but not between A and B.

- It can take longer to discover unreachable peers than reachable ones. This is because a reachable peer has to wait for the unreachable peer to establish the communication first.

For example, suppose Peer A (unreachable) starts before Peer B (reachable). The discovery mechanism of A attempts to connect to the (not-yet existing) Peer B. Since it fails, it will retry after  $n$  seconds. Right after that, B starts. If A would be reachable (and in B's peer list), the discovery

mechanism will immediately contact A. In this case, since A cannot be reached, B needs to wait until the discovery process of A decides to retry.

This effect can be minimized by modifying the QoS that controls the discovery mechanism used by A. In particular, you should set the *DomainParticipant's* DiscoveryConfig QoS policy's **min\_initial\_participant\_announcement\_period** to a small value.

Note that the concept of symmetric/asymmetric configuration is a local concept that only describes the communication mechanism between two peers. A reachable peer can be involved in symmetric communication with another reachable peer, and at the same time have asymmetric communication with an unreachable peer. When a peer attempts to communicate with a remote peer, it knows if the remote peer is reachable or not by looking at the transport address provided.

## 53.2 Configuring the TCP Transport

*TCP Transport* is distributed as a both shared and static library in `<NDDSHOME>/lib/<architecture>`. The library is called **nddstransporttcp**.

Mechanisms for Configuring the Transport:

- **By explicitly instantiating a new transport** (see [53.2.2 Explicitly Instantiating the TCP Transport Plugin on the next page](#)) and then registering it with the *DomainParticipant* (see [51.7 Installing Additional Builtin Transport Plugins with register\\_transport\(\) on page 979](#)). (Not available in the Java and C# APIs.)
- **Through the Property QoS policy** of the *DomainParticipant* (on Linux and Windows systems only). This process is described in [53.2.3 Configuring the TCP Transport with the Property QoSPolicy on page 1058](#).

This section describes:

- [53.2.1 Choosing a Transport Mode below](#)
- [53.2.2 Explicitly Instantiating the TCP Transport Plugin on the next page](#)
- [53.2.3 Configuring the TCP Transport with the Property QoSPolicy on page 1058](#)
- [53.2.4 Setting the Initial Peers on page 1061](#)
- [53.2.6 Support for External Hardware Load Balancers in TCP Transport Plugin on page 1063](#)
- [53.2.7 TCP/TLS Transport Properties on page 1065](#)

### 53.2.1 Choosing a Transport Mode

When you configure the TCP transport, you must choose one of the following types of communication:

- **TCP over LAN** — Communication between the two peers is not encrypted (data is written directly to a TCP socket). Each node can use all the possible interfaces available on that machine to receive connections. The node can only receive connections from machines that are on a local LAN.
- **TCP over WAN** — Communication is not encrypted (data is written directly to a TCP socket). The node can only receive connections from a specific port, which must be configured in the public router of the local network (WAN mode).
- **TLS over LAN** — This is similar to the TCP over LAN, where the node can use all the available network interfaces to TX/RX data (LAN nodes only), but in this mode, the data being written on the physical socket is encrypted first (through the **openssl** library). Performance (throughput and latency) may be less than TCP over LAN since the data needs to be encrypted before going on the wire. Discovery time may be longer with this mode because when the first connection is established, the two peers exchange handshake information to ensure line protection.
- **TLS over WAN** — The data is encrypted just like TLS over LAN, but it can be sent and received only from a specific port of the router.

**Note:** To use either TLS mode, you also need *RTI TLS Support*, which is available for purchase as a separate package. *TLS Support* uses TLS 1.3.

An instance of the transport can only communicate with other nodes that use the same transport mode.

You can specify the transport mode in either the `NDDS_Transport_TCPv4_Property_t` structure (see [53.2.7 TCP/TLS Transport Properties on page 1065](#)) or in the `parent.classid` on [page 1067](#) field of the Properties QoS (see [53.2.3 Configuring the TCP Transport with the Property QoSPolicy on page 1058](#)). Your choice of transport mode will also be reflected in the prefix you use for setting the initial peers (see [53.2.4 Setting the Initial Peers on page 1061](#)).

## 53.2.2 Explicitly Instantiating the TCP Transport Plugin

As described on [Page 1055](#), there are two ways to configure a transport plugin. This section describes the way that includes explicitly instantiating and registering a new transport. (The other way is to use the Property QoS mechanism, described in [53.2.3 Configuring the TCP Transport with the Property QoSPolicy on page 1058](#)).

Notes:

**This way of instantiating a transport is not supported in the Java and C# APIs.** If you are using Java or .NET, use the Property QoS mechanism described in [53.2.3 Configuring the TCP Transport with the Property QoSPolicy on page 1058](#).

To use this mechanism, there are **extra libraries that you must link into your program and an additional header file** that you must include. Please see [53.2.2.1 Additional Header Files and Include Directories on the next page](#) and [53.2.2.2 Additional Libraries and Compiler Flags on the next page](#) for details.

**To instantiate a TCP transport:**

Include the extra header file described in [53.2.2.1 Additional Header Files and Include Directories](#) below.

Instantiate a new transport by calling `NDDS_Transport_TCPv4_new()`:

```
NDDS_Transport_Plugin* NDDS_Transport_TCPv4_new (
    const struct NDDS_Transport_TCPv4_Property_t * property_in)
```

Register the transport by calling `NDDSTransportSupport::register_transport()`.

See the API Reference HTML documentation for details on these functions and the contents of the `NDDS_Transport_TCPv4_Property_t` structure.

**53.2.2.1 Additional Header Files and Include Directories**

To use the TCP Transport API, you must include an extra header file (in addition to those in listed in the Building Applications chapter in the [RTI Connex Core Libraries Platform Notes](#)):

```
#include "ndds/transport_tcp/transport_tcp_tcpv4.h"
```

Since the TCP Transport is in the same directory as Connex, no additional include paths need to be added for the TCP Transport API. (If this is not the case, you will need to specify the appropriate include path.)

**53.2.2.2 Additional Libraries and Compiler Flags**

To use the TCP Transport, you must add the `nddstransporttcp` library to the link phase of your application. There are four different kinds of libraries, depending on if you want a debug or release version, and static or dynamic linking with *Connex*.

**Note:** Make sure your chosen kinds of libraries (static, dynamic, release, or debug) are consistent with the other *Connex* libraries that your application links with. For example, if you are using RTI static core libraries, also use the static TCP Transport libraries. See Building Applications chapter in the [RTI Connex Core Libraries Platform Notes](#) .

For Linux systems, the libraries are:

- `libnddstransporttcp.a` — Release version, dynamic libraries
- `libnddstransporttcpd.a` — Debug version, dynamic libraries
- `libnddstransporttcpz.a` — Release version, static libraries
- `libnddstransporttcpzd.a` — Debug version, static libraries

For Windows systems, the libraries are:

- **NDDSTRANSPORTTCP.LIB** — Release version, dynamic libraries
- **NDDSTRANSPORTTCPD.LIB** — Debug version, dynamic libraries
- **NDDSTRANSPORTTCPZ.LIB** — Release version, static libraries
- **NDDSTRANSPORTTCPZD.LIB** — Debug version, static libraries

#### Notes for using TLS:

To use either TLS mode (see [53.2.1 Choosing a Transport Mode on page 1055](#)), you also need *RTI TLS Support*, which is available for purchase as a separate package. The TLS library (**libnddstls.so** or **NDDSTLS.LIB**, depending on your platform) must be in your library search path (pointed to by the environment variable `LD_LIBRARY_PATH` on Linux systems, `Path` on Windows systems, `DYLD_LIBRARY_PATH` on macOS systems).

If you already have `$NDDSHOME/lib/<architecture>` in your library search path, no extra steps are needed to use TLS once *TLS Support* is installed.

Even if you link everything statically, you must make sure that the location for `$NDDSHOME/lib/<architecture>` (or wherever the TLS library is located) is in your search path. When the TCP Transport Plugin is explicitly instantiated, the TLS library is loaded dynamically, even if you use static linking for everything else. To load TLS libraries statically, please see [53.2.3 Configuring the TCP Transport with the Property QoSPolicy below](#).

Your search path must also include the location for the OpenSSL library, which is used by the TLS library.

### 53.2.3 Configuring the TCP Transport with the Property QoSPolicy

The [47.19 PROPERTY QoSPolicy \(DDS Extension\) on page 837](#) allows you to set up name/value pairs of data and attach them to an entity, such as a *DomainParticipant*.

Like all QoS policies, there are two ways to specify the Property QoS policy:

**Programmatically**, as described in this section and [Chapter 49 Configuring QoS Programmatically on page 900](#). This includes using the `add_property()` operation to attach name/value pairs to the Property QoSPolicy and then configuring the *DomainParticipant* to use that QoSPolicy (by calling `set_qos()` or specifying QoS values when the *DomainParticipant* is created).

**With an XML QoS Profile**, as described in [Configuring QoS with XML \(Chapter 50 on page 905\)](#). This causes *Connex*t to dynamically load the TCP Transport library at runtime and then implicitly create and register the transport plugin.

**Note:** Dynamically load the TCP Transport library only if your application also links dynamically with the *Connex*t core libraries. Do not mix static and dynamic libraries; see Building Applications chapter in the [RTI Connex](#)t Core Libraries Platform Notes .

To add name/value pairs to the Property QoS policy, use the **add\_property()** operation:

```
DDS_ReturnCode_t DDSPropertyQoSPolicyHelper::add_property
    (DDS_PropertyQoSPolicy policy, const char * name,
     const char * value, DDS_Boolean propagate)
```

For more information on **add\_property()** and the other operations in the `DDSPropertyQoSPolicyHelper` class, see [Table 47.34 PropertyQoSPolicyHelper Operations](#), as well as the API Reference HTML documentation.

The ‘name’ part of the name/value pairs is a predefined string. The property names for the *TCP Transport* are described in [Table 53.1 Properties for NDDS\\_Transport\\_TCPv4\\_Property\\_t](#).

Here are the basic steps, taken from the example Hello World application (for details, please see the example application.)

1. Get the default *DomainParticipant* QoS from the `DomainParticipantFactory`.

```
DDSDomainParticipantFactory::get_instance()->
    get_default_participant_qos(participant_qos);
```

2. Disable the builtin transports.

```
participant_qos.transport_builtin.mask =
    DDS_TRANSPORTBUILTIN_MASK_NONE;
```

3. Set up the *DomainParticipant*'s Property QoS.

- a. Load the plugin.

```
DDSPropertyQoSPolicyHelper::add_property (
    participant_qos.property,
    "dds.transport.load_plugins",
    "dds.transport.TCPv4.tcpl",
    DDS_BOOLEAN_FALSE);
```

- b. Specify the transport plugin library.

```
DDSPropertyQoSPolicyHelper::add_property (
    participant_qos.property,
    "dds.transport.TCPv4.tcpl.library",
    "nddstransporttcp",
    DDS_BOOLEAN_FALSE);
```

- c. Specify the transport's ‘create’ function.

```
DDSPropertyQoSPolicyHelper::add_property (
    participant_qos.property,
    "dds.transport.TCPv4.tcpl.create_function",
    "NDDS_Transport_TCPv4_create", DDS_BOOLEAN_FALSE);
```

- d. Set the transport to work in a WAN configuration with a public address:

```
DDSPropertyQoSPolicyHelper::add_property (
    participant_qos.property,
```

```
"dds.transport.TCPv4.tcp1.parent.classid",
"NDDS_TRANSPORT_CLASSID_TCPV4_WAN", DDS_BOOLEAN_FALSE);
DDSPropertyQoSPolicyHelper::add_property (
    participant_qos.property,
    "dds.transport.TCPv4.public_address",
    "182.181.2.31",
    DDS_BOOLEAN_FALSE);
```

- e. Specify any other properties, as needed.

#### 4. Create the *DomainParticipant* using the modified QoS.

```
participant =
    DDSTheParticipantFactory->create_participant (
        domainId,
        participant_qos,
        NULL /* listener */,
        DDS_STATUS_MASK_NONE);
```

**Property changes should be made before the transport is loaded**—either before the *DomainParticipant* is enabled, before the first *DataWriter/DataReader* is created, or before the builtin topic reader is looked up, whichever one happens first.

### 53.2.3.1 Configuring the TCP Transport to be Loaded Statically

Similar to the previous example, here are the basic steps to load the TCP Transport plugin statically.

**Note:** Statically load the TCP Transport library only if your application also links statically with the *Connex* core libraries. Do not mix static and dynamic libraries; see the Building Applications chapter in the [RTI Connex Core Libraries Platform Notes](#)

#### 1. Get the default *DomainParticipant* QoS from the *DomainParticipantFactory*.

```
DDSDomainParticipantFactory::get_instance()->
    get_default_participant_qos(participant_qos);
```

#### 2. Disable the builtin transports.

```
participant_qos.transport_builtin.mask =
    DDS_TRANSPORTBUILTIN_MASK_NONE;
```

#### 3. Set up the *DomainParticipant*'s Property QoS.

- a. Load the plugin.

```
DDSPropertyQoSPolicyHelper::add_property
    (participant_qos.property,
     "dds.transport.load_plugins",
     "dds.transport.TCPv4.tcp1", DDS_BOOLEAN_FALSE);
```

- b. Specify the transport's 'create' function pointer.

```
DDSPropertyQoSPolicyHelper::add_pointer_property
(participant_qos.property,
 "dds.transport.TCPv4.tcpl.create_function_ptr",
 (void*)NDDS_Transport_TCPv4_create);
```

- c. Set the transport to work in a WAN configuration with a public address:

```
DDSPropertyQoSPolicyHelper::add_property
(participant_qos.property,
 "dds.transport.TCPv4.tcpl.parent.classid",
 "NDDS_TRANSPORT_CLASSID_TCPV4_WAN",
 DDS_BOOLEAN_FALSE);
DDSPropertyQoSPolicyHelper::add_property
(participant_qos.property,
 "dds.transport.TCPv4.tcpl.public_address",
 "182.181.2.31",
 DDS_BOOLEAN_FALSE);
```

- d. Specify any other properties, as needed.

4. Create the *DomainParticipant* using the modified QoS.

```
participant = DDSTheParticipantFactory->create_participant
(domainId, participant_qos,
 NULL /* listener */, DDS_STATUS_MASK_NONE);
```

### 53.2.3.2 Loading the TLS Support Library Statically

The process to load the TLS Support library statically is similar, but in this case both the **tls\_create\_function\_ptr** and **tls\_delete\_function\_ptr** properties need to be set as follows:

```
DDSPropertyQoSPolicyHelper::add_pointer_property
(participant_qos.property,
 "dds.transport.TCPv4.tcpl.tls_create_function_ptr",
 (void*)RTITLS_ConnectionEndpointFactoryTLsv4_create);
DDSPropertyQoSPolicyHelper::add_pointer_property
(participant_qos.property,
 "dds.transport.TCPv4.tcpl.tls_delete_function_ptr",
 (void*)RTITLS_ConnectionEndpointFactoryTLsv4_delete);
```

## 53.2.4 Setting the Initial Peers

**Note:** You must specify the initial peers (you cannot use the defaults because multicast cannot be used with TCP).

For *TCP Transport*, the addresses of the initial peers (NDDS\_DISCOVERY\_PEERS) that will be contacted during the discovery process have the following format:

- For WAN communication using TCP: **tcpv4\_wan://<IP address or hostname>:<port>**
- For WAN communication using TLS: **tlsv4\_wan://<IP address or hostname>:<port>**
- For LAN communication using TCP: **tcpv4\_lan://<IP address or hostname>:<port>**
- For LAN communication using TLS: **tlsv4\_lan://<IP address or hostname>:<port>**

For example (enter this on one line):

```
export NDDS_DISCOVERY_PEERS=
tcpv4_wan://10.10.1.165:7400,tcpv4_wan://10.10.1.111:7400,tcpv4_lan://192.168.1.1:7500
```

When the TCP transport is configured for LAN communication (with the [parent.classid on page 1067](#) property), the IP address is the LAN address of the peer and the port is the server port used by the transport (the [server\\_bind\\_port on page 1072](#) property).

When the TCP transport is configured for WAN communication (with the [parent.classid on page 1067](#) property), the IP address is the WAN or public address of the peer and the port is the public port that is used to forward traffic to the server port in the TCP transport.

## 53.2.5 RTPS Locator Format

As described in [Chapter 26 Discovered RTPS Locators and Changes with IP Mobility on page 348](#), an RTPS locator is an n-tuple (transport, address, port) that describes how to reach a remote endpoint.

The RTI TCP Transport locator has the following format:

0	8	16	24	31
DDS_Long kind				
DDS_UnsignedLong rtps_port				
DDS_Octet address[16]				

where kind can be one of the following values:

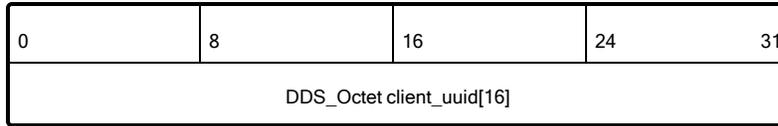

```
#define NDDS_TRANSPORT_CLASSID_TCPV4_LAN (8)
#define NDDS_TRANSPORT_CLASSID_TCPV4_WAN (9)
#define NDDS_TRANSPORT_CLASSID_TLSV4_LAN (10)
#define NDDS_TRANSPORT_CLASSID_TLSV4_WAN (11)
```

There are two subkinds of RTI TCP locator, which differ in the way the address field is mapped. You can distinguish the two subkinds from each other by comparing bytes address[8] and address[9]:

- If address[8]==0xFF and address[9]==0xFF, the RTI TCP locator is an RTI TCP server locator, and the format of the address[16] is as follows:

0	8	16	24	31
DDS_Octet network_address[8]				
0xFF	0xFF	DDS_UnsignedShort public_address_port		
DDS_Octet ip_address[4]				

- Otherwise, the RTI TCP locator is an RTI TCP client locator, and the format of the address[16] is as follows:

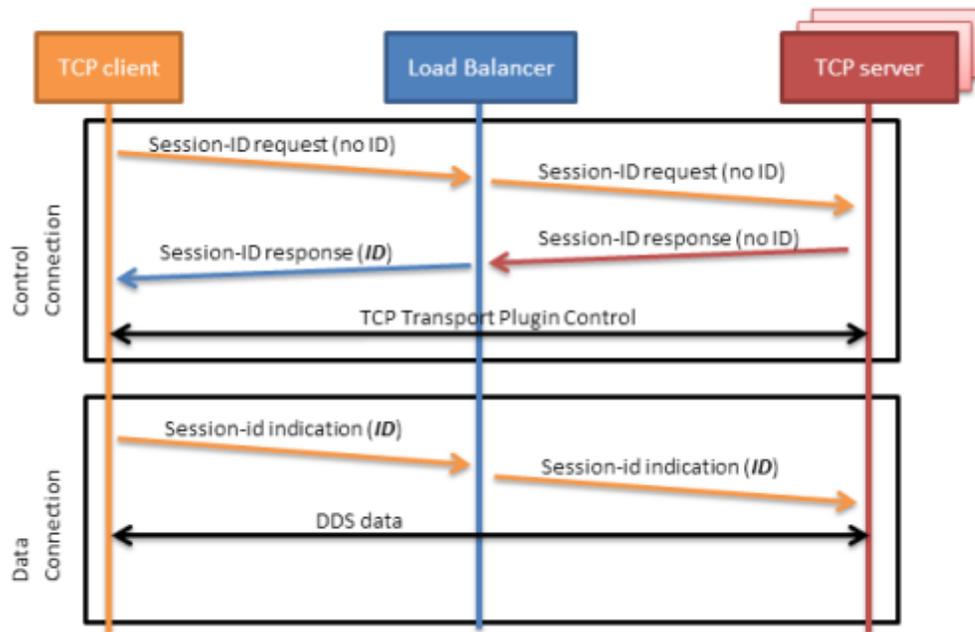

## 53.2.6 Support for External Hardware Load Balancers in TCP Transport Plugin

For two *Connex*t applications to communicate, the TCP Transport Plugin needs to establish 4-6 connections between the two communicating applications. The plugin uses these connections to exchange DDS data (discovery or user data) and TCP Transport Plugin control messages.

With the default configuration, the TCP Transport Plugin does not support external load balancers. This is because external load balancers do not forward the traffic to a unique TCP Transport Plugin server, but they divide the connections among multiple servers. Because of this behavior, when an application running a TCP Transport Plugin client tries to establish all the connections to an application running a TCP Transport Plugin server, the server may not receive all the required connections.

In order to support external load balancers, the TCP Transport Plugin provides a session-ID negotiation feature. When session-ID negotiation is enabled (by setting the `negotiate_session_id` property to true), the TCP Transport Plugin will perform the negotiation depicted in [Figure 53.4: Session-ID Negotiation on the next page](#).

Figure 53.4: Session-ID Negotiation

During the session-ID negotiation, the TCP Transport Plugin exchanges three types of messages:

**Session-ID Request:** This message is sent from the client to the server. The server must respond with a session-ID response.

**Session-ID Response:** This message is sent from the server to the client as a response to a session-ID request. The client will store the session ID contained in this message.

**Session-ID Indication:** This message is sent from the client to the server; it does not require a response from the server.

The negotiation consists of the following steps:

1. The TCP client sends a session-ID request with the session ID set to zero.
2. The TCP server sends back a session-ID response with the session ID set to zero.
3. The external load balancer modifies the session-ID response, setting the session ID with a value that is meaningful to the load balancer and identifies the session.
4. The TCP client receives the session-ID response and stores the received session ID.
5. For each new connection, the TCP client sends a session-ID indication containing the stored session ID. This will allow the load balancer to redirect to the same server all the connections with the same session ID.

### 53.2.6.1 Session-ID Messages

[TCP Payload for Session-ID Message below](#) depicts the TCP payload of a session-ID message. The payload consists of 48 bytes. In particular, your load balancer needs to read/modify the following two fields:

**CTRLTYPE:** This field allows a load balancer to identify session-ID messages. Its value (two bytes) varies according to the session-ID message type: 0x0c05 for a request, 0x0d05 for a response, or 0x0c15 for an indication.

**SESSION-ID:** This field consists of 16 bytes that the load balancer can freely modify according to its requirements.

*TCP Payload for Session-ID Message*

00	01	02	03	04	05	06	07	08	09	10	11	12	13	14	15
RTI reserved				0xDD	0x54	0xDD	0x55	CTRLTYPE		RTI reserved					
16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
RTI reserved															
32	33	34	35	36	37	38	39	40	41	42	43	44	45	46	47
SESSION-ID															

To ensure all the TCP connections within the same session are directed to the same server, you must configure your load balancer to perform the two following actions:

Modify the SESSION-ID field in the *session-id response* with a value that identifies the session within the load balancer.

Make the load-balancing decision according to the value of the SESSION-ID field in the session-ID indication.

## 53.2.7 TCP/TLS Transport Properties

[Table 53.1 Properties for NDDS\\_Transport\\_TCPv4\\_Property\\_t](#) describes the TCP and TLS transport properties.

**Note:** To use TLS, you also need *RTI TLS Support*, which is a separate component.

Table 53.1 Properties for `NDDS_Transport_TCPv4_Property_t`

Property Name (prefix with 'dds.transport.TCPv4.tcp1.')	Description
dds.transport.load_plugins (Note: this does not take a prefix)	<b>Required</b> Comma-separated strings indicating the prefix names of all plugins that will be loaded by <i>Connex</i> . For example: " <b>dds.transport.TCPv4.tcp1</b> ". You will use this string as the prefix to the property names. Note: you can load up to 8 plugins.
library	<b>Only required if linking dynamically</b> If used, must be "nddstransporttcp". This library must be in your library search path (pointed to by the environment variable LD_LIBRARY_PATH on Linux systems, Path on Windows systems, DYLD_LIBRARY_PATH on macOS systems).
create_function	<b>Only required if linking dynamically</b> If used, must be "NDDS_Transport_TCPv4_create".
create_function_ptr	<b>Only required if linking statically</b> Defines the function pointer to the TCP Transport Plugin creation function. Used for loading TCP Transport Plugin statically. Must be set to the NDDS_Transport_TCPv4_create function pointer.
tls_create_function_ptr	Defines the function pointer to the TLS Support creation function. Used for loading TLS Support libraries statically. Must be set to the RTITLS_ConnectionEndpointFactoryTLSv4_create function pointer. Note: In order to have effect, the <b>tls_delete_function_ptr</b> property must also be set.
tls_delete_function_ptr	Defines the function pointer to the TLS Support deletion function. Used for loading TLS Support libraries statically. Must be set to the RTITLS_ConnectionEndpointFactoryTLSv4_delete function pointer. Note: In order to have effect, the <b>tls_create_function_ptr</b> property must also be set.
aliases	Used to register the transport plugin returned by <b>NDDS_Transport_TCPv4_create()</b> (as specified by <b>&lt;TCP_prefix&gt;.create_function</b> ) to the <i>DomainParticipant</i> . Aliases should be specified as a comma-separated string, with each comma delimiting an alias. If it is not specified, the prefix—without the leading " <b>dds.transport</b> "—is used as the default alias for the plugin. For example, if the <b>&lt;TRANSPORT_PREFIX&gt;</b> is " <b>dds.transport.mytransport</b> ", the default alias for the plugin is " <b>mytransport</b> ".

<sup>1</sup>Assuming you used 'dds.transport.TCPv4.tcp1' as the alias to load the plugin. If not, change the prefix to match the string used with dds.transport.load\_plugins. This prefix must begin with 'dds.transport.'

Table 53.1 Properties for NDDS\_Transport\_TCPv4\_Property\_t

Property Name (prefix with 'dds.transport.TCPv4.tcp1.')	Description
parent.classid	<p>Must be set to one of the following values:</p> <ul style="list-style-type: none"> <li>• NDDS_TRANSPORT_CLASSID_TCPV4_LAN for TCP communication within a LAN</li> <li>• NDDS_TRANSPORT_CLASSID_TLSV4_LAN for TLS communication within a LAN</li> <li>• NDDS_TRANSPORT_CLASSID_TCPV4_WAN for TCP communication across LANs and firewalls</li> <li>• NDDS_TRANSPORT_CLASSID_TLSV4_WAN for TLS communication across LAN and firewalls</li> </ul> <p>Default: <b>NDDS_TRANSPORT_CLASSID_TCPV4_LAN</b></p> <p><b>Note:</b> To use either TLS mode, you also need <i>RTI TLS Support</i> which is available for purchase as a separate package.</p>
parent.gather_send_buffer_count_max	<p>Specifies the maximum number of buffers that <i>Connex</i>t can pass to the <b>send()</b> function of the transport plugin.</p> <p>The transport plugin <b>send()</b> API supports a gather-send concept, where the <b>send()</b> call can take several discontinuous buffers, assemble and send them in a single message. This enables <i>Connex</i>t to send a message from parts obtained from different sources without first having to copy the parts into a single contiguous buffer.</p> <p>However, most transports that support a gather-send concept have an upper limit on the number of buffers that can be gathered and sent. Setting this value will prevent <i>Connex</i>t from trying to gather too many buffers into a send call for the transport plugin.</p> <p><i>Connex</i>t requires all transport-plugin implementations to support a gather-send of least a minimum number of buffers. This minimum number is defined as <b>NDDS_TRANSPORT_PROPERTY_GATHER_SEND_BUFFER_COUNT_MIN</b>.</p> <p>Default: 128</p>
parent.message_size_max	<p>The maximum size of a message in bytes that can be sent or received by the transport plugin. Above this size, DDS-level fragmentation will occur. See <a href="#">34.3 Large Data Fragmentation on page 524</a>.</p> <p>Default: 65536</p>

<sup>1</sup>Assuming you used 'dds.transport.TCPv4.tcp1' as the alias to load the plugin. If not, change the prefix to match the string used with dds.transport.load\_plugins. This prefix must begin with 'dds.transport.'

Table 53.1 Properties for NDDS\_Transport\_TCPv4\_Property\_t

Property Name (prefix with 'dds.transport.TCPv4.tcp1.')	Description
parent.allow_interfaces_list	<p>A list of strings, each identifying a range of interface addresses or an interface name that can be used by the transport. Interfaces must be specified as comma-separated strings, with each comma delimiting an interface.</p> <p>For example: 10.10.*, 10.15.*</p> <p>If the list is non-empty, this "white" list is applied before <a href="#">parent.deny_interfaces_list</a> below. The <i>DomainParticipant</i> will use the resulting list of interfaces to inform its remote participant(s) about which unicast addresses may be used to send data to that <i>DomainParticipant</i>.</p> <p><b>Note:</b> This property does not affect the interfaces that the transport uses to send unicast data from that <i>DomainParticipant</i>. That decision is made by the OS based on the destination address.</p> <p>You must manage the memory of the list. The memory may be freed after the <i>DomainParticipant</i> is deleted.</p> <p>The left-to-right order of this list matters if you are using the <b>max_interface_count</b> to limit the allowable interfaces further. See <b>max_interface_count</b>.</p> <p>Default: empty list that represents all available interfaces</p>
parent.deny_interfaces_list	<p>A list of strings, each identifying a range of interface addresses or an interface name that will not be used by the transport. If the list is non-empty, deny the use of these interfaces. Interfaces must be specified as comma-separated strings, with each comma delimiting an interface.</p> <p>For example: 10.10.*</p> <p>This "black" list is applied after <a href="#">parent.allow_interfaces_list</a> above and filters out the interfaces that should <i>not</i> be used for receiving data.</p> <p><b>Note:</b> This property does not affect the interfaces that the transport uses to send unicast data from a <i>DomainParticipant</i>. That decision is made by the OS based on the destination address.</p> <p>You must manage the memory of the list. The memory may be freed after the <i>DomainParticipant</i> is deleted.</p> <p>Default: empty list that represents no denied interfaces</p>

<sup>1</sup>Assuming you used 'dds.transport.TCPv4.tcp1' as the alias to load the plugin. If not, change the prefix to match the string used with dds.transport.load\_plugins. This prefix must begin with 'dds.transport.'

Table 53.1 Properties for NDDS\_Transport\_TCPv4\_Property\_t

Property Name (prefix with 'dds.transport.TCPv4.tcp1.')	Description
parent.max_interface_count	<p>How many of the addresses in your allowed interfaces list are used, at most, at any time.</p> <p>This feature is useful if you want to control the network interfaces on which your <i>DomainParticipants</i> receive data. For example, if you have one wired and one wireless interface in your allowed interfaces list <i>both</i> up and running, and <b>max_interface_count</b> is set to 1, the <i>DomainParticipant</i> will receive data over the interface you list first in the <b>allow_interfaces_list</b>—for example, the wired one. If the wired interface is not in use (for example, the device is undocked), then the <i>DomainParticipant</i> will receive data only over the next available up-and-running interface in your <b>allow_interfaces_list</b>, which would be the wireless one.</p> <p><i>Connex</i>t selects the preferred interface(s) by iterating over the list of allowed interfaces until the first <b>max_interfaces_count</b> of active interfaces encountered are announced. The order of iteration is left to right as specified in the <b>allow_interfaces_list</b> setting.</p> <p>This setting applies only if the <b>allow_interfaces_list</b> is not empty.</p> <p>The <b>max_interface_count</b> setting does not consider end-to-end connectivity to select interfaces. The decision is based purely on whether interfaces are up or down in a node. Therefore, this feature is not intended to be used in the following scenarios:</p> <ul style="list-style-type: none"> <li>• A <i>DomainParticipant</i> is not reachable by other <i>DomainParticipants</i> in all the interfaces in the <b>allow_interfaces_list</b>. This could occur if the <i>DomainParticipant</i> is in different subnets, and some of these subnets cannot be reached by other <i>DomainParticipants</i>.</li> <li>• End-to-end connectivity issues lead to situations in which the interfaces selected after applying <b>max_interface_count</b> cannot be reached by other <i>DomainParticipants</i>.</li> </ul> <p><b>Note:</b> If a pattern string in the <b>allow_interfaces_list</b> matches multiple interface addresses, and <b>max_interface_count</b> is set to a finite value, the order for the matching allowed interfaces is decided based on the order in which the operating system provides these interfaces.</p> <p>Default: LENGTH_UNLIMITED Range: [1, LENGTH_UNLIMITED]</p>
send_socket_buffer_size	<p>Size, in bytes, of the send buffer of a socket used for sending. On most operating systems, <b>setsockopt()</b> will be called to set the <code>SO_SNDBUF</code> to the value of this parameter.</p> <p>This value must be greater than or equal to <a href="#">parent.message_size_max on page 1067</a>, or -1. The maximum value is operating system-dependent.</p> <p>When set to -1, <b>setsockopt()</b> (or equivalent) will not be called to size the send buffer of the socket. The transport will use the OS default.</p> <p>Default: 131072</p>

<sup>1</sup>Assuming you used 'dds.transport.TCPv4.tcp1' as the alias to load the plugin. If not, change the prefix to match the string used with dds.transport.load\_plugins. This prefix must begin with 'dds.transport.'

Table 53.1 Properties for NDDS\_Transport\_TCPv4\_Property\_t

Property Name (prefix with 'dds.transport.TCPv4.tcp1.')	Description
recv_socket_buffer_size	<p>Size, in bytes, of the receive buffer of a socket used for receiving. On most operating systems, <b>setsockopt()</b> will be called to set the RECVBUF to the value of this parameter.</p> <p>This value must be greater than or equal to <a href="#">parent.message_size_max on page 1067</a>, or -1. The maximum value is operating-system dependent.</p> <p>When set to -1, <b>setsockopt()</b> (or equivalent) will not be called to size the receive buffer of the socket. The transport will use the OS default.</p> <p>Default: 131072</p>
ignore_loopback_interface	<p>Prevents the transport plugin from using the IP loopback interface.</p> <p>This property is ignored when <a href="#">parent.classid on page 1067</a> is NDDS_TRANSPORT_CLASSID_TCPV4_WAN or NDDS_TRANSPORT_CLASSID_TLsv4_WAN.</p> <p>Two values are allowed:</p> <ul style="list-style-type: none"> <li>• 0: Enable local traffic via this plugin. The plugin will only use and report the IP loopback interface only if there are no other network interfaces (NICs) up on the system.</li> <li>• 1: Disable local traffic via this plugin. This means "do not use the IP loopback interface, even if no NICs are discovered." This setting is useful when you want applications running on the same node to use a more efficient plugin like shared memory instead of the IP loopback.</li> </ul> <p>Default: 1</p>
ignore_nonrunning_interfaces	<p>It prevents the transport plugin from using a network interface that is not reported as RUNNING by the operating system.</p> <p>The transport checks the flags reported by the operating system for each network interface upon initialization. An interface which is not reported as UP will not be used. This property allows the same check to be extended to the IFF_RUNNING flag implemented by some operating systems. The RUNNING flag is defined to mean that "all resources are allocated" and may be off if no link is detected (e.g., the network cable is unplugged).</p> <p>Two values are allowed:</p> <ul style="list-style-type: none"> <li>• 0: Do not check the RUNNING flag when enumerating interfaces, just make sure the interface is UP.</li> <li>• 1: Check the flag when enumerating interfaces, and ignore those that are not reported as RUNNING. This can be used on some operating systems to cause the transport to ignore interfaces that are enabled but not connected to the network.</li> </ul> <p>Default: 1</p>

<sup>1</sup>Assuming you used 'dds.transport.TCPv4.tcp1' as the alias to load the plugin. If not, change the prefix to match the string used with dds.transport.load\_plugins. This prefix must begin with 'dds.transport.'

Table 53.1 Properties for NDDS\_Transport\_TCPv4\_Property\_t

Property Name (prefix with 'dds.transport.TCPv4.tcp1.')	Description
transport_priority_mask	<p>Mask for the transport priority field. This is used in conjunction with <a href="#">transport_priority_mapping_low</a> below/ <a href="#">transport_priority_mapping_high</a> below to define the mapping from DDS transport priority to the IPv4 TOS field. Defines a contiguous region of bits in the 32-bit transport priority value that is used to generate values for the IPv4 TOS field on an outgoing socket.</p> <p>For example, the value 0x0000ff00 causes bits 9-16 (8 bits) to be used in the mapping. The value will be scaled from the mask range (0x0000 -0xff00 in this case) to the range specified by low and high.</p> <p>If the mask is set to zero, then the transport will not set IPv4 TOS for send sockets.</p> <p>Default: 0</p>
transport_priority_mapping_low	<p>Sets the low and high values of the output range to IPv4 TOS.</p> <p>These values are used in conjunction with <a href="#">transport_priority_mask</a> above to define the mapping from DDS transport priority to the IPv4 TOS field. Defines the low and high values of the output range for scaling.</p>
transport_priority_mapping_high	<p>Note that IPv4 TOS is generally an 8-bit value.</p> <p>Default transport_priority_mapping_low: 0</p> <p>Default transport_priority_mapping_high: 0xFF</p>
interface_poll_period	<p>Specifies the period in milliseconds to query for changes in the state of all the interfaces.</p> <p>See <a href="#">interface_poll_period</a> in <a href="#">51.6 Setting Builtin Transport Properties with the PropertyQosPolicy</a> on page 960</p>
server_socket_backlog	<p>The backlog parameter determines what is the maximum length of the queue of pending connections.</p> <p>Default: 5</p>
public_address	<p><b>Required for WAN communication (see note below)</b></p> <p>Public IP address and port (WAN address and port) (separated with ':') associated with the transport instantiation.</p> <p>For example: 10.10.9.10:4567</p> <p>This field is used only when <a href="#">parent.classid</a> on page 1067 is NDDS_TRANSPORT_CLASSID_TCPV4_WAN or NDDS_TRANSPORT_CLASSID_TLsv4_WAN.</p> <p>The public address and port are necessary to support communication over WAN that involves Network Address Translators (NATs). Typically, the address is the public address of the IP router that provides access to the WAN. The port is the IP router port that is used to reach the private <a href="#">server_bind_port</a> on the next page inside the LAN from the outside. This value is expressed as a string in the form: <b>ip[:port]</b>, where <b>ip</b> represents the IPv4 address and port is the external port number of the router.</p> <p>Host names are not allowed in the <b>public_address</b> because they may resolve to an internet address that is not what you want (i.e., 'localhost' may map to your local IP or to 127.0.0.1).</p> <p><b>Note:</b> If you are using an asymmetric configuration, <b>public_address</b> does not have to be set for the non-public peer.</p>

<sup>1</sup>Assuming you used 'dds.transport.TCPv4.tcp1' as the alias to load the plugin. If not, change the prefix to match the string used with dds.transport.load\_plugins. This prefix must begin with 'dds.transport.'

Table 53.1 Properties for NDDS\_Transport\_TCPv4\_Property\_t

Property Name (prefix with 'dds.transport.TCPv4.tcp1.')	Description
bind_interface_address	<p>The TCP transport can be configured to bind all sockets to a specified interface.</p> <p>If NULL, the sockets will be bound to the special IP address INADDR_ANY. This address allows the sockets to receive packets destined to any of the interfaces.</p> <p>This field should be set in multi-homed systems communicating across NAT routers.</p>
server_bind_port	<p>Private IP port (inside the LAN) used by the transport to accept TCP connections.</p> <p>If this property is set to zero (which is only a valid configuration when <b>parent.classid</b> is NDDS_TRANSPORT_CLASSID_TCPV4_WAN or NDDS_TRANSPORT_CLASSID_TLsv4_WAN), the transport will operate in "asymmetric mode" and it will disable the internal server socket, making it impossible for external peers to connect to this node. In this case, the node is considered unreachable and will communicate only using the asymmetric mode with other (reachable) peers. For more information about the available modes of operation for the transport, please refer to <a href="#">53.1 TCP Communication Scenarios on page 1051</a>.</p> <p>For WAN communication, if <b>server_bind_port</b> is set to a value other than zero, this port must be forwarded to a public port in the NAT-enabled router that connects to the outer network.</p> <p>The <b>server_bind_port</b> cannot be shared among multiple participants on a common host. On most operating systems, attempting to reuse the same <b>server_bind_port</b> for multiple participants on a common host will result in a "port already in use" error. However, Windows systems will not recognize if the <b>server_bind_port</b> is already in use; therefore care must be taken to properly configure Windows systems.</p> <p>Default: 7400</p>
read_buffer_allocation	<p>Allocation settings applied to read buffers.</p> <p>These settings configure the initial number of buffers, the maximum number of buffers and the buffers to be allocated when more buffers are needed.</p> <p>Default:</p> <ul style="list-style-type: none"> <li>• <b>read_buffer_allocation.initial_count</b> = 2</li> <li>• <b>read_buffer_allocation.max_count</b> = -1 (unlimited)</li> <li>• <b>read_buffer_allocation.incremental_count</b> = -1 (number of buffers will keep doubling on each allocation until it reaches <b>max_count</b>)</li> </ul>

<sup>1</sup>Assuming you used 'dds.transport.TCPv4.tcp1' as the alias to load the plugin. If not, change the prefix to match the string used with dds.transport.load\_plugins. This prefix must begin with 'dds.transport.'

Table 53.1 Properties for NDDS\_Transport\_TCPv4\_Property\_t

Property Name (prefix with 'dds.transport.TCPv4.tcp1.')	Description
write_buffer_allocation	<p>Allocation settings applied to buffers used for asynchronous (non-blocking) send. To enable asynchronous send, set the property <b>force_asynchronous_send</b> to 1.</p> <p>These settings configure the initial number of buffers, the maximum number of buffers, and the buffers to be allocated when more buffers are needed.</p> <p>Default:</p> <ul style="list-style-type: none"> <li>• <b>write_buffer_allocation.initial_count</b> = 4</li> <li>• <b>write_buffer_allocation.max_count</b> = 32</li> <li>• <b>write_buffer_allocation.incremental_count</b> = 2</li> </ul> <p>The pool of buffers can be configured to be shared across all the TCP connections created by the TCP Transport or to be exclusive for a connection by setting the property <b>shared_write_buffer_allocation</b> to 1. The default value is 0.</p> <p>Note that for the write buffer pool, the <b>max_count</b> is not set to unlimited. This is to avoid having a fast writer quickly exhaust all the available system memory, in case of a temporary network slowdown. When this write buffer pool reaches the maximum, a new message will replace the oldest message that is not currently in the process of being sent. This guarantees that new messages are prioritized, while at the same time not running into a situation in which messages are not received. Messages that are replaced and not sent may be resent later depending on the application's QoS (if the transport is used for reliable communication, the data will still be sent eventually).</p>
shared_write_buffer_allocation	<p>This property determines whether the pool of buffers created with asynchronous (non-blocking) send is shared or exclusive per TCP connection. Sharing this buffer across connections may lead to less memory consumption. However, high-throughput connections may starve low-throughput connections. This is why the default value is 0. The size of the buffer pool can be configured using the property <b>write_buffer_allocation</b>.</p> <p>Default: 0</p>
control_buffer_allocation	<p>Allocation settings applied to buffers used to serialize and send control messages.</p> <p>These settings configure the initial number of buffers, the maximum number of buffers and the buffers to be allocated when more buffers are needed.</p> <p>Default:</p> <ul style="list-style-type: none"> <li>• <b>control_buffer_allocation.initial_count</b> = 2</li> <li>• <b>control_buffer_allocation.max_count</b> = -1 (unlimited)</li> <li>• <b>control_buffer_allocation.incremental_count</b> = -1 (number of buffers will keep doubling on each allocation until it reaches <b>max_count</b>)</li> </ul>

<sup>1</sup>Assuming you used 'dds.transport.TCPv4.tcp1' as the alias to load the plugin. If not, change the prefix to match the string used with dds.transport.load\_plugins. This prefix must begin with 'dds.transport.'

Table 53.1 Properties for `NDDS_Transport_TCPv4_Property_t`

Property Name (prefix with 'dds.transport.TCPv4.tcp1.')	Description
control_message_allocation	<p>Allocation settings applied to control messages.</p> <p>These settings configure the initial number of messages, the maximum number of messages and the messages to be allocated when more messages are needed.</p> <p>Default:</p> <ul style="list-style-type: none"> <li>• <code>control_message_allocation.initial_count</code> = 2</li> <li>• <code>control_message_allocation.max_count</code> = -1 (unlimited)</li> <li>• <code>control_message_allocation.incremental_count</code> = -1 (number of messages will keep doubling on each allocation until it reaches <code>max_count</code>)</li> </ul>
control_attribute_allocation	<p>Allocation settings applied to control messages attributes.</p> <p>These settings configure the initial number of attributes, the maximum number of attributes and the attributes to be allocated when more attributes are needed.</p> <p>Default:</p> <ul style="list-style-type: none"> <li>• <code>control_attribute_allocation.initial_count</code> = 2</li> <li>• <code>control_attribute_allocation.max_count</code> = -1 (unlimited)</li> <li>• <code>control_attribute_allocation.incremental_count</code> = -1 (number of attributes will keep doubling on each allocation until it reaches <code>max_count</code>)</li> </ul>
force_asynchronous_send	<p>Forces asynchronous send. When this parameter is set to 0, the TCP Transport will attempt to send data as soon as the internal <code>send()</code> function is called. When it is set to 1, the transport will make a copy of the data to send in an internal send buffer and enqueue it. Data will be sent as soon as the low-level socket buffer has space.</p> <p>Setting this option to 0 (default) should provide better latency. However, in high-throughput scenarios, a 0 setting may cause the low-level <code>send()</code> function to block until the data is physically delivered to the lower socket buffer. For an application writing data at a very fast rate, the 0 setting may cause the caller thread to block if the send socket buffer is full. This could produce lower throughput in those conditions (the caller thread could prepare the next packet while waiting for the send socket buffer to become available).</p> <p>The size of the buffer pool created by setting this option to 1 can be configured using the property <code>write_buffer_allocation</code>. In addition, the TCP Transport can be used to create one buffer pool per connection or a single buffer pool shared across all TCP connections by using the property <code>shared_write_buffer_allocation</code>.</p> <p>Default: 0</p>
max_packet_size	<p>The maximum size of a TCP segment.</p> <p>This parameter is only supported on Linux architectures.</p> <p>By default, the maximum size of a TCP segment is based on the network MTU for destinations on a local network, or on a default 576 for destinations on non-local networks. This behavior can be changed by setting this parameter to a value between 1 and 65535.</p> <p>Default: -1 (default behavior)</p>

<sup>1</sup>Assuming you used 'dds.transport.TCPv4.tcp1' as the alias to load the plugin. If not, change the prefix to match the string used with `dds.transport.load_plugins`. This prefix must begin with 'dds.transport.'

Table 53.1 Properties for NDDS\_Transport\_TCPv4\_Property\_t

Property Name (prefix with 'dds.transport.TCPv4.tcp1.')	Description
enable_keep_alive	<p>Configures the sending of KEEP_ALIVE messages in TCP.</p> <p>Setting this value to 1, causes a KEEP_ALIVE packet to be sent to the remote peer if a long time passes with no other data sent or received.</p> <p>This feature is implemented only on architectures that provide a low-level implementation of the TCP keep-alive feature.</p> <p>On Windows systems, the TCP keep-alive feature can be globally enabled through the system's registry: <b>\HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Tcpip\Parameters</b>.</p> <p>Refer to MSDN documentation for more details.</p> <p>Default: 0</p>
keep_alive_time	<p>Specifies the interval of inactivity in seconds that causes TCP to generate a KEEP_ALIVE message.</p> <p>This parameter is only supported on Linux and Mac architectures.</p> <p>Default: -1 (OS default value)</p>
keep_alive_interval	<p>Specifies the interval in seconds between KEEP_ALIVE retries.</p> <p>This parameter is only supported on Linux architectures.</p> <p>Default: -1 (OS default value)</p>
keep_alive_retry_count	<p>The maximum number of KEEP_ALIVE retries before dropping the connection.</p> <p>This parameter is only supported on Linux architectures.</p> <p>Default: -1 (OS default value)</p>
user_timeout	<p>Changes the default OS TCP User Timeout configuration. If set to a value greater than 0, it specifies the maximum amount of time in seconds that transmitted data may remain unacknowledged before TCP will forcibly close the corresponding connection and return ETIMEDOUT to the application.</p> <p>If set to 0, TCP Transport plugin will use the system default.</p> <p>Currently this feature is supported only on Linux 2.6.37 and higher platforms.</p> <p>Default: 0 (use system's default).</p>
connection_liveliness	<p>Configures the connection liveliness feature. See <a href="#">53.2.7.1 Connection Liveliness on page 1083</a>.</p> <p>Defaults:</p> <ul style="list-style-type: none"> <li>• connection_liveliness.enable: 0</li> <li>• connection_liveliness.lease_duration: 10</li> <li>• connection_liveliness.assertions_per_lease_duration: 3</li> </ul>

<sup>1</sup>Assuming you used 'dds.transport.TCPv4.tcp1' as the alias to load the plugin. If not, change the prefix to match the string used with dds.transport.load\_plugins. This prefix must begin with 'dds.transport.'

Table 53.1 Properties for NDDS\_Transport\_TCPv4\_Property\_t

Property Name (prefix with 'dds.transport.TCPv4.tcp1.')	Description
event_thread	<p>Configures the event thread used by the TCP Transport plugin for providing some features.</p> <p>Defaults:</p> <ul style="list-style-type: none"> <li>• event_thread.priority: THREAD_PRIORITY_DEFAULT</li> <li>• event_thread.stack_size: THREAD_STACK_SIZE_DEFAULT</li> <li>• event_thread.mask: PRIORITY_ENFORCE   STDIO</li> </ul>
disable_nagle	<p>Disables the TCP nagle algorithm.</p> <p>When this property is set to 1, TCP segments are always sent as soon as possible, which may result in poor network utilization.</p> <p>Default: 0</p>
logging_verbosity_bitmap	<p>Bitmap that specifies the verbosity of log messages from the transport.</p> <p>Logging values:</p> <ul style="list-style-type: none"> <li>• -1 (0xffffffff): do not change the current verbosity</li> <li>• 0x00: silence</li> <li>• 0x01: fatal error</li> <li>• 0x02: errors</li> <li>• 0x04: warnings</li> <li>• 0x08: local</li> <li>• 0x10: remote</li> <li>• 0x20: periodic</li> <li>• 0x100: other (used for control protocol tracing)</li> <li>• 13F: all (fatal error, errors, warnings, local, remote, periodic, and other)</li> </ul> <p>You can combine these values by logically ORing them together.</p> <p>Default: -1 (meaning, do not change the current verbosity, which is fatal errors, errors, and warnings by default)</p> <p>Note: the logging verbosity is a global property shared across the multiple instances of the TCP Transport within an application. If you create a new TCP Transport instance with <b>logging_verbosity_bitmap</b> different than -1, the change will affect all the other instances as well.</p> <p>Note: The option of 0x100 (other) is used only for tracing the internal control protocol. Since the output is very verbose, this feature is enabled only in the debug version of the TCP Transport library (<code>libnndstransporttcpd.so / LIBNDDSTRANSPORTD.LIB</code>).</p>

<sup>1</sup>Assuming you used 'dds.transport.TCPv4.tcp1' as the alias to load the plugin. If not, change the prefix to match the string used with `dds.transport.load_plugins`. This prefix must begin with 'dds.transport.'

Table 53.1 Properties for NDDS\_Transport\_TCPv4\_Property\_t

Property Name (prefix with 'dds.transport.TCPv4.tcp1.')	Description
security_logging_verbosity_bitmap	<p>Bitmap that specifies the verbosity of security-related log messages from the transport. These are usually messages generated by OpenSSL.</p> <p>Logging values:</p> <ul style="list-style-type: none"> <li>• -1 (0xffffffff): use the current verbosity of the transport, which is a global property (see <b>logging_verbosity_bitmap</b>)</li> <li>• 0x00: silence</li> <li>• 0x01: fatal error</li> <li>• 0x02: errors</li> <li>• 0x04: warnings</li> <li>• 0x08: local</li> <li>• 0x10: remote</li> <li>• 0x20: periodic</li> </ul> <p>You can combine these values by logically ORing them together.</p> <p>Default: -1 (use the current verbosity of the transport, which is a global property (see <b>logging_verbosity_bitmap</b>))</p> <p>Note: The security logging verbosity is a global property shared across the multiple instances of the TCP Transport within an application. If you create a new TCP Transport instance, the value of <b>security_logging_verbosity_bitmap</b> will be applied to all the other instances as well.</p>
socket_monitoring_kind	<p>Configures the socket monitoring API used by the transport. This property can have the following values:</p> <ul style="list-style-type: none"> <li>• SELECT: The transport uses the POSIX select API to monitor sockets.</li> <li>• WINDOWS_IOCP: The transport uses Windows I/O completion ports to monitor sockets. This value only applies to Windows systems.</li> <li>• WINDOWS_WAITFORMULTIPLEOBJECTS: The transport uses the API WaitForMultipleObjects to monitor sockets. This value only applies to Windows systems.</li> </ul> <p>Default: SELECT</p> <p><b>Note:</b> The value selected for this property may affect transport performance and scalability. On Windows systems, using WINDOWS_IOCP provides the best performance and scalability.</p>

<sup>1</sup>Assuming you used 'dds.transport.TCPv4.tcp1' as the alias to load the plugin. If not, change the prefix to match the string used with dds.transport.load\_plugins. This prefix must begin with 'dds.transport.'

Table 53.1 Properties for NDDS\_Transport\_TCPv4\_Property\_t

Property Name (prefix with 'dds.transport.TCPv4.tcp1.')	Description
windows_iocp	<p>Configures I/O completion ports when <a href="#">socket_monitoring_kind on the previous page</a> is set to WINDOWS_IOCP.</p> <p>This setting configures the number of threads the plugin creates to process I/O completion packets (thread_pool_size) and the number of those threads that the operating system can allow to concurrently run (concurrency_value).</p> <p>Defaults:  windows_iocp.thread_pool_size: 2  windows_iocp.concurrency_value: 1</p>
send_crc	<p>When set to 1, enables the computation of the CRC for sent RTI TCP messages.</p> <p>Default: 0</p>
force_crc_check	<p>When set to 1, forces the checking of the CRC for received RTI TCP messages. By default, the TCP Transport plugin will only validate the CRC if the CRC is present in the received message. If this property is set to 1, TCP Transport will drop messages not including the CRC.</p> <p>Default: 0</p>
negotiate_session_id	<p>When set to 1, the TCP Transport Plugin will perform a session negotiation that will help external load balancers identify all the connections associated with a particular session between two Connex applications. This keeps the connections from being divided among multiple servers and ensures proper communication.</p> <p>For more information about this property, see <a href="#">53.2.6 Support for External Hardware Load Balancers in TCP Transport Plugin on page 1063</a>.</p> <p>Default: 0</p> <p><b>Note:</b> The value of this property must be consistent among all the applications running the TCP Transport Plugin. If two applications have a different value for this property, they may not communicate.</p>
outstanding_connection_cookies	<p>Maximum number of outstanding connection cookies allowed by the transport when acting as server.</p> <p>A connection cookie is a token provided by a server to a client; it is used to establish a data connection. Until the data connection is established, the cookie cannot be reused by the server.</p> <p>To avoid wasting memory, it is good practice to set a cap to the maximum number of connection cookies (pending connections).</p> <p>When the maximum value is reached, a client will not be able to connect to the server until new cookies become available.</p> <p>Range: 1 or higher, or -1 (which means an unlimited number).</p> <p>Default: 100</p>

<sup>1</sup>Assuming you used 'dds.transport.TCPv4.tcp1' as the alias to load the plugin. If not, change the prefix to match the string used with dds.transport.load\_plugins. This prefix must begin with 'dds.transport.'

Table 53.1 Properties for NDDS\_Transport\_TCPv4\_Property\_t

Property Name (prefix with 'dds.transport.TCPv4.tcp1.')	Description
outstanding_connection_cookies_life_span	<p>Maximum lifespan (in seconds) of the cookies associated with pending connections.</p> <p>If a client does not connect to the server before the lifespan of its cookie expires, it will have to request a new cookie.</p> <p>Range: 1 second or higher, or -1</p> <p>Default: -1, which means an unlimited amount of time (effectively disabling the feature).</p>
send_max_wait_sec	<p>Controls the maximum time (in seconds) the low-level <code>sendto()</code> function is allowed to block the caller thread when the TCP send buffer becomes full.</p> <p>If the bandwidth used by the transport is limited, and the sender thread tries to push data faster than the OS can handle, the low-level <code>sendto()</code> function will block the caller until there is some room available in the queue. Limiting this delay eliminates the possibility of deadlock and increases the response time of the internal DDS thread.</p> <p>This property affects both CONTROL and DATA streams. It only affects SYNCHRONOUS send operations. Asynchronous sends never block a send operation.</p> <p>For synchronous <code>send()</code> calls, this property limits the time the DDS sender thread can block for a full send buffer. If it is set too large, Connex not only won't be able to send more data, it also won't be able to receive any more data because of an internal resource mutex.</p> <p>Setting this property to 0 causes the low-level function to report an immediate failure if the TCP send buffer is full.</p> <p>Setting this property to -1 causes the low-level function to block forever until space becomes available in the TCP buffer.</p> <p>Default: 3 seconds.</p>
client_connection_negotiation_timeout	<p>Timeout (in seconds) for negotiating a client data connection.</p> <p>The TCP Transport plugin requires some negotiation before establishing a connection. This property controls the maximum time (in seconds) a client data connection negotiation can remain in progress.</p> <p>In particular, it controls a maximum timeout for requesting and replying to a server logical port request.</p> <p>If the negotiation of a connection has not completed after the specified timeout, the negotiation will restart, and if there is an associated data connection, it will be closed. This way, the TCP Transport plugin can retry the process of establishing and negotiating that connection.</p> <p>Range: 1 second or higher.</p> <p>Default: 10 seconds</p>

<sup>1</sup>Assuming you used 'dds.transport.TCPv4.tcp1' as the alias to load the plugin. If not, change the prefix to match the string used with `dds.transport.load_plugins`. This prefix must begin with 'dds.transport.'

Table 53.1 Properties for NDDS\_Transport\_TCPv4\_Property\_t

Property Name (prefix with 'dds.transport.TCPv4.tcp1.')	Description
server_connection_negotiation_timeout	<p>Timeout (in seconds) for negotiating a server data connection.</p> <p>The TCP Transport plugin requires some negotiation before establishing a connection. This property controls the maximum time (in seconds) a server data connection negotiation can remain in progress.</p> <p>In particular, it controls a maximum timeout for requesting and replying to a client logical port request.</p> <p>If the negotiation of a connection has not completed after the specified timeout, the negotiation will restart, and if there is an associated data connection, it will be closed. This way, the TCP Transport plugin can retry the process of establishing and negotiating that connection.</p> <p>Range: 1 second or higher. Default: 10 seconds</p>
initial_handshake_timeout	<p>Timeout (in seconds) for the initial handshake for a connection.</p> <p>Once a connection is established, TCP transport will exchange some information to identify itself and the connection. This process is known as the initial handshake of a connection, and if using TLS the TCP Transport plugin will also exchange additional information to secure the connection.</p> <p>This property controls the maximum time (in seconds) the initial handshake for a connection can remain in progress. If the handshake has not completed after the specified timeout, the connection will be closed. This way, the TCP Transport plugin can restart the process of establishing and handshaking that connection.</p> <p>Range: 1 second or higher. Default: 10 seconds</p>
tls.verify.ca_file	<p>A string that specifies the name of file containing Certificate Authority certificates. File should be in PEM format. See the OpenSSL manual page for SSL_load_verify_locations for more information.</p> <p><b>To enable TLS, ca_file or ca_path is required; both may be specified (at least one is required).</b></p>
tls.verify.ca_path	<p>A string that specifies paths to directories containing Certificate Authority certificates. Files should be in PEM format and follow the OpenSSL-required naming conventions. See the OpenSSL manual page for SSL_CTX_load_verify_locations for more information.</p> <p>The Certificate Authority subject name hash values must be available in the directories. You may generate them by running openssl rehash (available in OpenSSL 1.1.0 or above) in each directory.</p> <p><b>To enable TLS, ca_file or ca_path is required; both may be specified (at least one is required).</b></p>
tls.verify.verify_depth	Maximum certificate chain length for verification.
tls.verify.crl_file	<p>Name of the file containing the Certificate Revocation List.</p> <p>File should be in PEM format.</p>

<sup>1</sup>Assuming you used 'dds.transport.TCPv4.tcp1' as the alias to load the plugin. If not, change the prefix to match the string used with dds.transport.load\_plugins. This prefix must begin with 'dds.transport.'

Table 53.1 Properties for NDDS\_Transport\_TCPv4\_Property\_t

Property Name (prefix with 'dds.transport.TCPv4.tcp1.')	Description
tls.identity.certificate_chain	String containing an identifying certificate (in PEM format) or certificate chain (appending intermediate CA certs in order). <b>An identifying certificate is required for secure communication.</b> The string must be sorted starting with the certificate to the highest level (root CA). If this is specified, certificate_chain_file must be empty.
tls.identity.certificate_chain_file	File containing identifying certificate (in PEM format) or certificate chain (appending intermediate CA certs in order). <b>An identifying certificate is required for secure communication.</b> The file must be sorted starting with the certificate to the highest level (root CA). If this is specified, <b>certificate_chain</b> must be empty. Optionally, a private key may be appended to this file. If no private key option is specified, this file will be used to load a private key.
tls.identity.private_key_password	A string that specifies the password for private key.
tls.identity.private_key	String containing private key (in PEM format). At most one of <b>private_key</b> and <b>private_key_file</b> may be specified. If no private key is specified (all values are NULL), the private key will be read from the certificate chain file.
tls.identity.private_key_file	File containing private key (in PEM format). At most one of <b>private_key</b> and <b>private_key_file</b> may be specified. If no private key is specified (all values are NULL), the private key will be read from the certificate chain file.
tls.identity.rsa_private_key	String containing additional RSA private key (in PEM format). For use if both an RSA and non-RSA key are required for the selected cipher. At most one of <b>rsa_private_key</b> and <b>rsa_private_key_file</b> may be specified. At most one of <b>rsa_private_key</b> and <b>rsa_private_key_file</b> may be specified.
tls.identity.rsa_private_key_file	File containing additional RSA private key (in PEM format). For use if both an RSA and non-RSA key are required for the selected cipher. At most one of <b>rsa_private_key</b> and <b>rsa_private_key_file</b> may be specified. At most one of <b>rsa_private_key</b> and <b>rsa_private_key_file</b> may be specified.
tls.cipher.cipher_list	List of available TLS ciphers when communicating with <i>Connex</i> 6.0.0 or below. See the OpenSSL manual page for <code>SSL_set_cipher_list</code> for more information on the format of this string. Default: NULL
tls.cipher.ciphersuites	List of available TLS ciphersuites when communicating with <i>Connex</i> 6.0.1 or above. See the OpenSSL manual page for <code>SSL_CTX_set_ciphersuites</code> for more information on the format of this string. Default: NULL

<sup>1</sup>Assuming you used 'dds.transport.TCPv4.tcp1' as the alias to load the plugin. If not, change the prefix to match the string used with dds.transport.load\_plugins. This prefix must begin with 'dds.transport.'

Table 53.1 Properties for NDDS\_Transport\_TCPv4\_Property\_t

Property Name (prefix with 'dds.transport.TCPv4.tcp1.')	Description
tls.cipher.dh_param_files	List of available Diffie-Hellman (DH) key files. For example: "foo.h:2048,bar.h:1024" means: dh_param_files[0].file = foo.pem, dh_param_files[0].bits = 2048, dh_param_files[1].file = bar.pem, dh_param_files[1].bits = 1024
tls.cipher.engine_id	ID of OpenSSL cipher engine to request.
disable_interface_tracking	If this variable is set, the automatic change detection over the system network interfaces will be disabled.  See <a href="#">disable_interface_tracking</a> in <a href="#">51.6 Setting Builtin Transport Properties with the PropertyQosPolicy</a> on page 960
force_interface_poll_detection	This property forces the interface tracker to use a polling method to detect changes to the network interfaces in IP mobility scenarios. It only applies to operating systems that support asynchronous notifications of interface changes.  If set to TRUE, the interface tracker will use a polling method that queries the interfaces periodically to detect the changes. If set to FALSE, the interface tracker will use the operating system's default method.  Basically, this property allows you—for an operating system that supports asynchronous notification—to use the polling method instead.  Default: FALSE

<sup>1</sup>Assuming you used 'dds.transport.TCPv4.tcp1' as the alias to load the plugin. If not, change the prefix to match the string used with dds.transport.load\_plugins. This prefix must begin with 'dds.transport.'

Table 53.1 Properties for NDDS\_Transport\_TCPv4\_Property\_t

Property Name (prefix with 'dds.transport.TCPv4.tcp1.')	Description
property_validation_action	<p>By default, property names given in the <a href="#">47.19 PROPERTY QosPolicy (DDS Extension) on page 837</a> are validated to avoid using incorrect or unknown names (for example, due to a typo). This property configures the validation of the property names associated with the transport:</p> <ul style="list-style-type: none"> <li>• <code>VALIDATION_ACTION_EXCEPTION</code>: validate the properties. Upon failure, log errors and fail.</li> <li>• <code>VALIDATION_ACTION_SKIP</code>: skip validation.</li> <li>• <code>VALIDATION_ACTION_WARNING</code>: validate the properties. Upon failure, log warnings and do not fail.</li> </ul> <p>If this property is not set, the property validation behavior will be the same as that of the <i>DomainParticipant</i>, which by default is <code>VALIDATION_ACTION_EXCEPTION</code>. See <a href="#">47.19.1 Property Validation on page 840</a> for more information.</p>
thread_name_prefix	<p>You can set this field with your own value, to help you identify the transport thread in a way that's meaningful to you. Do not exceed 8 characters.</p> <p>If you do not set this field, <i>Connex</i>t creates the following prefix:</p> <pre>'r' + 'Tr' + participant identifier + '\0'</pre> <p>Where 'r' indicates this is a thread from RTI, 'Tr' indicates the thread is related to a transport, and participant identifier contains 5 characters as follows:</p> <ul style="list-style-type: none"> <li>• If <code>participant_name</code> is set: The participant identifier will be the first 3 characters and the last 2 characters of the <code>participant_name</code>.</li> <li>• If <code>participant_name</code> is not set, then the identifier is computed as <code>domain_id</code> (3 characters) followed by <code>participant_id</code> (2 characters).</li> <li>• If <code>participant_name</code> is not set and the <code>participant_id</code> is set to -1 (default value), then the participant identifier is computed as the last 5 digits of the <code>rtps_instance_id</code> in the participant GUID.</li> </ul> <p>See <a href="#">Chapter 72 Identifying Threads Used by Connex</a>t on page 1196.</p>

### 53.2.7.1 Connection Liveliness

The `connection_liveliness` property configures the connection liveliness feature. When enabled, the TCP Transport plugin will periodically exchange some additional control traffic (liveliness requests/responses) over one of the connections between the TCP Client and Server. This traffic allows determining if a that connection is not alive anymore, and thus proceed to its close. This avoids depending on the OS notification about the status of the connection, potentially decreasing the time to reestablish lost connections.

The following parameters can be configured:

<sup>1</sup>Assuming you used 'dds.transport.TCPv4.tcp1' as the alias to load the plugin. If not, change the prefix to match the string used with `dds.transport.load_plugins`. This prefix must begin with 'dds.transport.'

- **connection\_liveliness.enable**: Enables or disables the feature.
- **connection\_liveliness.lease\_duration**: In seconds, the timeout by which the connection liveliness must be asserted or the connection will be considered not alive. It is also used as the period between connection liveliness checks. Therefore, the maximum time before a connection is marked as not alive is  $2 * \text{connection\_liveliness.lease\_duration}$ .
- **connection\_liveliness.assertions\_per\_lease\_duration**: The number of liveliness requests sent per each lease duration. Increasing this value will increase the overhead sent into the network, but it will also make the connection liveliness mechanism more robust.

This feature relies on the creation of an additional thread in the TCP Transport Plugin (the event thread). For more information about how to configure this thread, see the **event\_thread** in [Table 53.1 Properties for NDDS\\_Transport\\_TCPv4\\_Property\\_t](#).

Enabling this feature breaks backwards compatibility with TCP Transport plugins that do not include this feature.

# Part 9: Debugging and Monitoring Connex Applications

This section contains information on logging, troubleshooting, and monitoring *Connex* applications. For an up-to-date list of frequently asked questions, also see the Knowledge Base on the RTI Community Portal: <https://community.rti.com/kb>. There you can find example code, general information on *Connex*, performance information, troubleshooting tips, and technical details.

This section includes:

- [Logging \(Chapter 54 on page 1086\)](#)
- [Troubleshooting Discovery \(Chapter 55 on page 1117\)](#)
- [Heap Memory Monitoring \(Chapter 56 on page 1120\)](#)
- [Discovery Snapshots \(Chapter 57 on page 1121\)](#)
- [Network Capture \(Chapter 58 on page 1124\)](#)
- [RTI Monitoring Library \(Chapter 59 on page 1126\)](#)

# Chapter 54 Logging

See the following sections:

- [What Version am I Running? \(54.1 below\)](#)
- [Logging a Backtrace for Failures \(54.5 on page 1102\)](#)
- [Setting Warnings for Operation Delays \(54.4 on page 1101\)](#)
- [Configuring Connext Logging \(54.2 on page 1089\)](#)
- [Configuring Logging via XML \(54.3 on page 1099\)](#)
- [RTI Distributed Logger \(54.6 on page 1103\)](#)

## 54.1 What Version am I Running?

There are three ways to obtain version information:

- By looking at the revision files, as described in [54.1.1 Finding Version Information in Revision Files below](#).
- By using Visual Studio or the command line, as described in [54.1.2 Finding Version Information on Windows or Linux Systems on the next page](#).
- Programmatically at run time, as described in [54.1.3 Finding Version Information Programmatically on the next page](#).

### 54.1.1 Finding Version Information in Revision Files

In the top-level directory of your *Connext* installation (`${NDDSHOME}`), you will find text files that include revision information. The files are named `rev_<product>_rtids.<version>`. For example, you might see files called `rev_host_rtids.7.x.y` and `rev_persistence_rtids.7.x.y` (where `x` and `y` stand for the version numbers of the current release). Each file contains more details, such as a patch level and if the product is license managed.

For example:

```
Host Build 7.x.y rev 04 (0x04050200)
```

The revision files for *Connex* target libraries are in the same directory as the libraries (`${NDDSHOME}/lib/<architecture>`).

## 54.1.2 Finding Version Information on Windows or Linux Systems

Another way to find the version is with these commands:

- On Windows platforms, run the DUMPBIN utility that comes with Visual Studio®. (You could also use any other COFF dumper application.) For example:

```
DUMPBIN/HEADERS nddscore.dll
```

You will find the version number encoded in the 'image version' line in the 'OPTIONAL HEADER VALUES' section:

```
OPTIONAL HEADER VALUES
<snip>
50200.00 image version
<snip>
```

The format is `<major_version><minor_version><terciary_version>.<patch_version>`. For example, version 5.2.6.3 would appear as image version 50206.03.

- On Linux platforms, run the command **strings** on the library in question and filter for 'BUILD'. For example:

```
strings libnddsc.so | grep BUILD
```

You will see a string similar to

```
NDDSCORE_VERSION_5.2.6.0_BUILD_2017-01-27T15:43:23-08:00_RTI_RELEASE
```

## 54.1.3 Finding Version Information Programmatically

The methods in the `NDDSConfigVersion` class can be used to retrieve version information for the *Connex* product, the core library, and the C, C++ or Java libraries.

The version information includes four fields:

- A major version number
- A minor version number
- A release number
- A build number

Table 54.1 *NDDSConfigVersion Operations* lists the available operations (they will vary somewhat depending on the programming language you are using; consult the API Reference HTML documentation for more information).

**Table 54.1 NDDSConfigVersion Operations**

Purpose	Operation	Description
To retrieve version information in a structured format	<code>get_product_version</code>	Gets version information for the <i>Connex</i> product.
	<code>get_core_version</code>	Gets version information for the <i>Connex</i> core library.
	<code>get_c_api_version</code>	Gets version information for the <i>Connex</i> C library.
	<code>get_cpp_api_version</code>	Gets version information for the <i>Connex</i> C++ library.
To retrieve version information in string format	<code>to_string</code>	Converts the version information for each library into a string. The strings for each library are put in a single hyphen-delimited list.

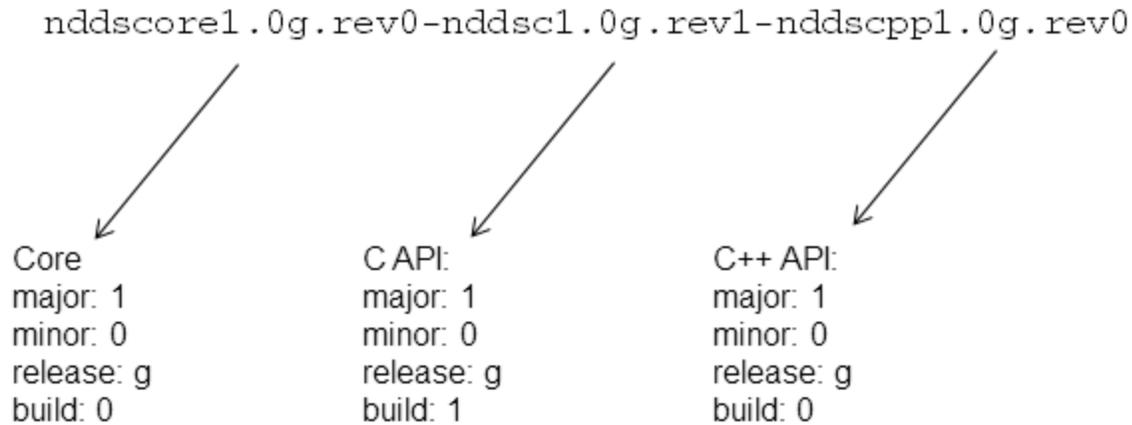

The `get_product_version()` operation returns a reference to a structure of type `DDS_ProductVersion_t`:

```
struct NDDSConfig_ProductVersion_t {
    DDS_Char  major;
    DDS_Char  minor;
    DDS_Char  release;
    DDS_Char  revision;
};
```

The other `get*_version()` operations return a reference to a structure of type `NDDSConfig_LibraryVersion_t`:

```
struct NDDSConfig_LibraryVersion_t {
    DDS_Long  major;
    DDS_Long  minor;
    char      release;
    DDS_Long  build;
};
```

The `to_string()` operation returns version information for the *Connex* core, followed by the C and C++ API libraries, separated by hyphens. For example:

## 54.2 Configuring Connex Logging

*Connex*'s builtin logging system provides several types of messages to help you debug your system and alert you to errors during run time. You can control how much information is reported and where it is logged. By default, the builtin logging system writes to the standard output, but you can configure it to use a logging file or an output device such as a custom logging device or the Distributed Logger. (See [54.6 RTI Distributed Logger on page 1103](#).) See also [Table 54.4 NDDSConfigLogger Operations](#) and [54.3 Configuring Logging via XML on page 1099](#) for information on configuring the builtin logging system.

How much information is logged is known as the *verbosity* setting. [Table 54.2 Message Logging Verbosity Levels](#) describes the increasing verbosity levels. Note that the verbosities are cumulative: logging at a high verbosity means also logging all lower verbosity messages. If you change nothing, the default verbosity will be set to `NDDS_CONFIG_LOG_VERBOSITY_ERROR`.

Logging at high verbosities can be detrimental to your application's performance. You should generally not set the verbosity above `NDDS_CONFIG_LOG_VERBOSITY_WARNING`, unless you are debugging a specific problem.

**Table 54.2 Message Logging Verbosity Levels**

Verbosity (NDDS_CONFIG_LOG_VERBOSITY_*)	Description	Log level values corresponding to this verbosity (NDDS_CONFIG_LOG_LEVEL_*)
SILENT	No messages will be logged. (lowest verbosity)	-
ERROR (default level for all categories)	Log only high-priority error messages. An error indicates something is wrong with how <i>Connex</i> is functioning. The most common cause of this type of error is an incorrect configuration.	ERROR, FATAL_ERROR
WARNING	Additionally log warning messages. A warning indicates that <i>Connex</i> is taking an action that may or may not be what you intended. Some configuration information is also logged at this verbosity to aid in debugging.	WARNING, ERROR, FATAL_ERROR
STATUS_LOCAL	Additionally log verbose information about the lifecycles of local <i>Connex</i> objects.	STATUS_LOCAL, WARNING, ERROR, FATAL_ERROR
STATUS_REMOTE	Additionally log verbose information about the lifecycles of remote <i>Connex</i> objects.	STATUS_REMOTE, STATUS_LOCAL, WARNING, ERROR, FATAL_ERROR
STATUS_ALL	Additionally log verbose information about periodic activities and <i>Connex</i> threads. (highest verbosity)	DEBUG, STATUS_REMOTE, STATUS_LOCAL, WARNING, ERROR, FATAL_ERROR

You will typically change the verbosity of all of *Connex* at once. However, in the event that such a strategy produces too much output, you can further discriminate among the messages you would like to see. The types of messages logged by *Connex* fall into the categories listed in [Table 54.3 Message Logging Categories](#); each category can be set to a different verbosity level.

**Table 54.3 Message Logging Categories**

Category (NDDS_CONFIG_LOG_CATEGORY_*)	Description
PLATFORM	Messages about the underlying platform (hardware and OS).
COMMUNICATION	Messages about data serialization and deserialization, and network traffic.
DATABASE	Messages about the internal database of <i>Connex</i> objects.
ENTITIES	Messages about local and remote entities and some of the discovery process. (To see all discovery-related messages, use the DISCOVERY category.)
API	Messages about <i>Connex</i> 's API layer, such as method argument validation and what QoS is being used (for details on QoS information, see <a href="#">50.2.3.6 Viewing Resolved QoS Values on page 925</a> ).
DISCOVERY	Messages pertaining to discovery.

Table 54.3 Message Logging Categories

Category (NDDS_CONFIG_LOG_CATEGORY_*)	Description
SECURITY	Messages pertaining to <i>Security Plugins</i> . See the "Security Events and Logging" section in the <i>RTI Security Plugins User's Manual</i> for more information.
ALL	Messages about all of the categories (default value)

The methods in the **NDDSConfigLogger** class can be used to change verbosity settings, as well as the destination and format of the logged messages. [Table 54.4 NDDSConfigLogger Operations](#) lists the available operations; consult the API Reference HTML documentation for more information.

Table 54.4 NDDSConfigLogger Operations

Purpose	Operation	Description
Change Verbosity for all Categories	get_verbosity	Gets the current verbosity. If per-category verbosity is used, returns the highest verbosity of any category.
	set_verbosity	Sets the verbosity of all categories.
Change Verbosity for a Specific Category	get_verbosity_by_category	Gets/Sets the verbosity for a specific category.
	set_verbosity_by_category	
Change Destination of Logged Messages	get_output_file	Returns the file to which messages are being logged, or NULL for the default destination (standard output on most platforms).
	set_output_file	Redirects future logged messages to a set of files. For better performance when log messages are generated frequently, the log messages are not flushed into a file immediately after they are generated. In other words, while writing a log message, <i>Connex</i> only calls the function <code>fwrite()</code> ; it does not call the function <code>fflush()</code> . If your application requires a different flushing behavior, you may configure a custom logging device (see <a href="#">54.2.2 Customizing the Handling of Generated Log Messages on page 1099</a> ).
	get_output_device	Returns the logging device installed with the logger.
	set_output_device	Registers a specified logging device with the logger. See <a href="#">54.2.2 Customizing the Handling of Generated Log Messages on page 1099</a>

Table 54.4 NDDSConfigLogger Operations

Purpose	Operation	Description
Change Message Format	get_print_format	Gets/Sets the current message format for the log level NDDS_CONFIG_LOG_LEVEL_ERROR. See <a href="#">54.2.1 Format of Logged Messages below</a> .
	set_print_format	
	get_print_format_by_log_level	Gets/Sets the current message format, by log level, that <i>Connexit</i> is using to log diagnostic information.
	set_print_format_by_log_level	

For example, to change the verbosity of all messages in the SECURITY category:

```
NDDS_Config_Logger_set_verbosity_by_category(
    logger,
    NDDS_CONFIG_LOG_CATEGORY_SECURITY,
    NDDS_CONFIG_LOG_VERBOSITY_STATUS_ALL);
```

## 54.2.1 Format of Logged Messages

You can control the amount of information in each message with the `set_print_format()` or `set_print_format_by_log_level()` operation (see [Table 54.4 NDDSConfigLogger Operations](#)). The format options are listed in [Table 54.5 Message Formats](#).

**Table 54.5 Message Formats**

Message Format (NDDS_CONFIG_LOG_PRINT_FORMAT_*)	Description
DEFAULT	(default) Message, method name, log level, activity context (what was happening when the event occurred), and logging category.
TIMESTAMPED	Message, method name, log level, activity context, logging category, and timestamp.
VERBOSE	Message with all available context information (includes thread identifier, message location).
VERBOSE_TIMESTAMPED	Message with all available context information and timestamp.
DEBUG	Information (including message number and backtrace information) for internal debugging by RTI personnel.
MINIMAL	Message number and message location.
MAXIMAL	All available fields.

See also [54.2.1.3 Activity Context on the next page](#) and [54.5 Logging a Backtrace for Failures on page 1102](#).

By default, `NDDS_CONFIG_LOG_PRINT_FORMAT_DEFAULT` is assigned to all log levels except `FATAL_ERROR`. By default, `FATAL_ERROR` is assigned to `NDDS_CONFIG_LOG_PRINT_FORMAT_DEBUG`, which prints the backtrace information. See [Table 54.2 Message Logging Verbosity Levels](#).

You could use a less verbose **print format**, such as `NDDS_CONFIG_LOG_PRINT_FORMAT_MINIMAL`, for warnings, as follows:

```
NDDS_Config_Logger *logger = NDDS_Config_Logger_get_instance();
NDDS_Config_Logger_set_print_format_by_log_level(
    logger,
    NDDS_CONFIG_LOG_PRINT_FORMAT_MINIMAL,
    NDDS_CONFIG_LOG_LEVEL_WARNING);
```

You could use a more verbose **print format**, such as `NDDS_CONFIG_LOG_PRINT_FORMAT_DEBUG` (which contains the backtrace) when you are troubleshooting errors, as follows:

```
NDDS_Config_Logger *logger = NDDS_Config_Logger_get_instance();
NDDS_Config_Logger_set_print_format_by_log_level(
    logger,
    NDDS_CONFIG_LOG_PRINT_FORMAT_DEBUG,
    NDDS_CONFIG_LOG_LEVEL_ERROR);
```

This way, you will reduce the amount of logging on warnings, and errors will contain more information. This configuration is key to understanding and solving issues when needed.

Of course, you are not likely to recognize all of the method names; many of the operations that perform logging are deep within the implementation of *Connex*. However, in case of errors, logging will typically take place at several points within the call stack; the output thus implies the stack trace at the time the error occurred. You may only recognize the name of the operation that was the last to log its message (i.e., the function that called all the others); however, the entire stack trace is extremely useful to RTI support personnel in the event that you require assistance.

You may notice that many of the logged messages begin with an exclamation point character. This convention indicates an error and is intended to be reminiscent of the negation operator in many programming languages. For example, the message “!create socket” means “cannot create socket.”

### 54.2.1.1 Timestamps

Reported times are in seconds from a system-dependent starting time; these are equivalent to the output format from *Connex*. The timestamp is in the form YYYY-MM-DD HH:MM::SS.<microseconds>, where SS is the number of seconds and <microseconds> is a fraction of that second expressed in microseconds. Enabling timestamps will result in some additional overhead for clock access for every message that is logged.

Logging of timestamps is not enabled by default. To enable it, use `NDDS_Config_Logger` method `set_print_format()`.

### 54.2.1.2 Thread identification

Thread identification strings uniquely identify active threads when a message is output to the console. A thread may be a user (application) thread or one of several types of internal threads. See [Part 11: Connex Threading Model on page 1180](#).

Logging of thread IDs is not enabled by default. To enable it, use `NDDS_Config_Logger` method `set_print_format()`. It adds the thread name to the log message, so you know which thread is responsible for the message. See [Chapter 72 Identifying Threads Used by Connex on page 1196](#).

### 54.2.1.3 Activity Context

Many middleware APIs now store information in thread-specific storage about the activity context operation.

Activity Context provides more context about a logging message. It is a group of *resources* and *activities* associated with an action, such as the creation of an entity:

- A *resource* is an abstraction of an entity. It can contain attributes such as *Topic* or domain ID.
- An *activity* is a general task that a resource is doing, such as "Getting QoS."

The activity context is one of the **NDDS\_Config\_LogPrintFormat** DDS logging infrastructure formats. If a format that prints activity context is selected (see [Table 54.5 Message Formats](#)), then every time *Connex* logs a message, it will contain the contextual information.

For example, in the creation of a *DataWriter*, the activity context will provide information about:

- Resource: the *Publisher* creating the *DataWriter*. The attributes of the publisher will be GUID, *Entity* kind, name, and domain ID.
- Activity: entity creation. It will have two parameters, the *Entity* kind and the *Topic*—in the example below, "Writer" and "TestTopic."

The string representation of the above activity context would be:

```
[0x101A76B,0x79E5D71,0x50EE914:0x80000088{Entity=Pu,Name=TestPublisher,Domain=1}|CREATE
Writer WITH TOPIC TestTopic]
```

In this example, the activity context fields are as follows:

- GUID is **0x101A76B,0x79E5D71,0x50EE914:0x80000003**

```
[0x101A76B,0x79E5D71,0x50EE914:0x80000003
{Entity=Pu,Name=TestPublisher,Domain=1}|CREATE Writer WITH TOPIC TestTopic]
```

- **Entity Name=TestPublisher**

```
[0x101A76B,0x79E5D71,0x50EE914:0x80000003
{Entity=Pu,Name=TestPublisher,Domain=1}|CREATE Writer WITH TOPIC TestTopic]
```

- **Entity** kind is **Entity=Pu** (for Publisher)

```
[0x101A76B,0x79E5D71,0x50EE914:0x80000003
{Entity=Pu,Name=TestPublisher,Domain=1}|CREATE Writer WITH TOPIC TestTopic]
```

- Domain ID is **Domain=1**

```
[0x101A76B,0x79E5D71,0x50EE914:0x80000003
{Entity=Pu,Name=TestPublisher,Domain=1}|CREATE Writer WITH TOPIC TestTopic]
```

- Activity is **CREATE Writer WITH TOPIC TestTopic**

```
[0x101A76B,0x79E5D71,0x50EE914:0x80000003
{Entity=Pu,Name=TestPublisher,Domain=1}|CREATE Writer WITH TOPIC TestTopic]
```

When a *DataWriter* writes a sample, the activity context will provide information about:

- Resource: the *DataWriter* writing the sample. The attributes of the *DataWriter* will be GUID, name, *Entity* kind, *Topic*, data type, and domain ID.
- Activity: the writing of a sample.

The string representation of this activity context would be:

```
[0x101A76B,0x79E5D71,0x50EE914:0x1C1:0x80000003
{Name=TestDataWriter,Entity=DW,Topic=test,Type=Foo,Domain=1}|Write]
```

In this example, the additional activity context fields are as follows:

- **Topic=test**

```
[0x101A76B,0x79E5D71,0x50EE914:0x80000003
{Name=testDataWriterName,Entity=DW,Topic=test,Y=Foo,Domain=1}|Write]
```

- **Data Type=Foo**

```
[0x101A76B,0x79E5D71,0x50EE914:0x80000003
{Name=testDataWriterName,Entity=DW,Topic=test,Type=Foo,Domain=1}|Write]
```

When executing an event within the [Chapter 65 Event Thread on page 1185](#), activity context includes information about the activity the original thread was executing when it posted the event (in addition to any activities the event thread enters). Consider the following example:

```
WARNING [0xEF4B1953,0x05A7DFA5,0xE557BBB5:0x00000000|ASSERT REMOTE DR|:0x000003C2
{Entity=DW,Topic=DISCPublication,Type=DISCPublicationParameter,Domain=67}|LINK
0xC974B8F7,0x9597897A,0xE770A8EA:0x000003C7
{Type=DISCPublicationParameter}|LC:DISC]COMMENDSrWriterService_assertRemoteReader:The remote
reader with GUID 0xC974B8F7,0x9597897A,0xE770A8EA:0x000003C7 has no addressable multicast
locators.
```

This message is logged from the Event thread while running into a WARNING during the “LINK” activity. It includes the activity “ASSERT REMOTE DR” from the original thread that posted the event.

#### 54.2.1.3.1 Activity Context Strings and Attributes

The resources of the activity context can have multiple associated attributes. Those attributes provide extra information about the entity such as GUID prefix, *Topic*, data type (class), *Entity* kind, *Entity* name, and domain ID. The following tables describe how those attributes are represented.

**Table 54.6 Activity Context Attributes**

Attribute	Description
GUID	(given at the beginning of the context, such as: <b>0x101A76B,0x79E5D71,0x50EE914:0x1C1:0x80000003</b> )
Name	Name of the entity, such as <b>TestPublisher</b>
Entity	Entity kind, such as <b>Pu</b> for <b>Publisher</b>
Domain	Domain ID
Topic	<i>Topic</i> name

Attribute	Description
Type	Data type
MessageKind	Kind of message: "DATA", "HEARTBEAT", "GAP", or other message kind

Table 54.7 Activity Context Resources and Entities

Entity Kind	Entity Type
DP	DDS_DomainParticipant
Pu	DDS_Publisher
Su	DDS_Subscriber
Topic	DDS_Topic
DW	DDS_<*>DataWriter
DR	DDS_<*>DataReader

Table 54.8 Examples of Activity Context Activities

String	Operation
<b>Entity operations:</b>

GET SUBS	Participant::get_subscribers
LOOKUP Topic(<name>)	Participant::lookup_topicdescription
LOOKUP FlowController(<name>)	Participant::lookup_flowcontroller
IGNORE <Entity>(<host ID>)	Participant::ignore_<entity>

#### 54.2.1.3.2 Configuring Activity Context Attributes

The attributes that `NDDS_Config_ActivityContextAttribute` uses in the string representation of the activity context can be configured through a mask. This mask indicates what resource attributes are used when *Connex* logs a message or when the Heap Monitoring utility saves statistics for a memory allocation.

```
void NDDS_Config_ActivityContext_set_attribute_mask(
    NDDS_Config_ActivityContextAttributeKindMask attribute_mask);

enum NDDS_Config_ActivityContextAttributeKind {
    NDDS_CONFIG_ACTIVITY_CONTEXT_ATTRIBUTE_GUID_PREFIX,
    NDDS_CONFIG_ACTIVITY_CONTEXT_ATTRIBUTE_TOPIC,
    NDDS_CONFIG_ACTIVITY_CONTEXT_ATTRIBUTE_TYPE,
    NDDS_CONFIG_ACTIVITY_CONTEXT_ATTRIBUTE_ENTITY_KIND,
    NDDS_CONFIG_ACTIVITY_CONTEXT_ATTRIBUTE_DOMAIN_ID,
    NDDS_CONFIG_ACTIVITY_CONTEXT_ATTRIBUTE_ENTITY_NAME
}

#define NDDS_CONFIG_ACTIVITY_CONTEXT_ATTRIBUTE_MASK_DEFAULT
#define NDDS_CONFIG_ACTIVITY_CONTEXT_ATTRIBUTE_MASK_NONE
#define NDDS_CONFIG_ACTIVITY_CONTEXT_ATTRIBUTE_MASK_ALL
```

#### 54.2.1.4 Logging Category

The types of messages logged by *Connex* fall into the categories listed in [Table 54.3 Message Logging Categories](#); each category can be set to a different verbosity level. A subset of the existing categories can show up as part of the logged message. [Table 54.9 Loggable Categories](#) covers the list of logging category strings that can show up as part of logged messages (preceded by "LC:").

**Table 54.9 Loggable Categories**

String	Category
DISC	NDDS_CONFIG_LOG_CATEGORY_DISCOVERY
SEC	NDDS_CONFIG_LOG_CATEGORY_SECURITY

## 54.2.2 Customizing the Handling of Generated Log Messages

By default, the log messages generated by *Connex*t are sent to the standard output. You can redirect the log messages to a file by using the `set_output_file()` operation,

To further customize the management of the generated log messages, you can use the Logger's `set_output_device()` operation to install a user-defined logging device. The logging device must implement an interface with two operations: `write()` and `close()`.

*Connex*t will call the `write()` operation to write a new log message to the input device. The log message provides the text and the verbosity corresponding to the message.

*Connex*t will call the `close()` operation when the logging device is uninstalled.

**Note:** It is not safe to make any calls to the *Connex*t core library including calls to `DDS_DomainParticipant_get_current_time()` from any of the logging device operations.

For additional details on user-defined logging devices, see the API Reference HTML documentation (under **Modules, RTI Connex**t API Reference, **Configuration Utilities**).

## 54.3 Configuring Logging via XML

Logging can also be configured using the DomainParticipantFactory's [43.1 LOGGING QoS Policy \(DDS Extension\)](#) on page 690 with the tags, `<participant_factory_qos><logging>`. The fields in the LoggingQoSPolicy are described in XML using a 1-to-1 mapping with the equivalent C representation shown below:

```
struct DDS_LoggingQoSPolicy {
    NDDS_Config_LogVerbosity verbosity;
    NDDS_Config_LogCategory category;
    NDDS_Config_LogPrintFormat print_format;
    char * output_file;
};
```

The equivalent representation in XML:

```
<participant_factory_qos>
  <logging>
    <verbosity></verbosity>
    <category></category>
```

```

    <print_format></print_format>
  <output_file></output_file>
</logging>
</participant_factory_qos>

```

The attribute `<is_default_participant_factory_profile>` can be set to true for the `<qos_profile>` tag to indicate from which profile to use `<participant_factory_qos>`. If multiple QoS profiles have `<is_default_participant_factory_profile>` set to true, the last profile with `<is_default_participant_factory_profile>` set to true will be used.

If none of the profiles have set `<is_default_participant_factory_profile>` to true, the profile with `<is_default_qos>` set to true will be used.

In the following example, DefaultProfile2 will be used:

```

<dds xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:noNamespaceSchemaLocation="../xsd/rti_dds_qos_profiles.xsd">
  <!-- Qos Library -->
  <qos_library name="DefaultLibrary">
    <qos_profile name="DefaultProfile1"
      is_default_participant_factory_profile ="true">
      <participant_factory_qos>
        <logging>
          <verbosity>ALL</verbosity>
          <category>ENTITIES</category>
          <print_format>MAXIMAL</print_format>
          <output_file>LoggerOutput1.txt</output_file>
        </logging>
      </participant_factory_qos>
    </qos_profile>
    <qos_profile name=
      "DefaultProfile2"
      is_default_participant_factory_profile ="true">
      <participant_factory_qos>
        <logging>
          <verbosity>WARNING</verbosity>
          <category>API</category>
          <print_format>VERBOSE_TIMESTAMPED</print_format>
          <output_file>LoggerOutput2.txt</output_file>
        </logging>
      </participant_factory_qos>
    </qos_profile>
    <qos_profile name="DefaultProfile3" is_default_qos="true">
      <participant_factory_qos>
        <logging>
          <verbosity>ERROR</verbosity>
          <category>DATABASE</category>
          <print_format>VERBOSE</print_format>
          <output_file>LoggerOutput3.txt</output_file>
        </logging>
      </participant_factory_qos>
    </qos_profile>
  </qos_library>
</dds>

```

**Note:** The `LoggingQoSPolicy` is currently the only QoS policy that can be configured using the `<participant_factory_qos>` tag.

## 54.4 Setting Warnings for Operation Delays

You can configure logging a warning when a specific operation takes more time than expected. This capability is useful for discovering problems related to contentions, delays, and blocks. By default, these warnings are not logged. You have to explicitly enter a timeout period for the desired warning to see it. You can set these timeouts via properties in the [47.19 PROPERTY QoSPolicy \(DDS Extension\) on page 837](#).

The operations for which you can set timeouts are:

- **Send operation:** Print a warning message when the send operation time exceeds the time threshold configured by the property `dds.participant.logging.time_based_logging.send.timeout`. The output message will look like this:

```
It took '0.359548' seconds to send '96' bytes to
'shmem://903A:C1C4:91F3:A80F:CA5B:3B82:0000:0000:7661', which exceeds the time
threshold configured in 'dds.participant.logging.time_based_logging.send.timeout'."
```

- **Event operations:** Print a warning message when the event start or execution time exceeds the time threshold configured by the property `dds.participant.logging.time_based_logging.event.timeout`. The output message will look like this:

```
The event thread took '2.502871' seconds waiting to trigger the event, which exceeds
the time threshold configured in 'dds.participant.logging.time_based_
logging.event.timeout'.
```

```
The event thread took '1.436886' seconds executing the event, which exceeds the time
threshold configured in 'dds.participant.logging.time_based_logging.event.timeout'.
```

- **Process received data operation:** Print a warning message when the processing of a received message on a specific port exceeds a time threshold set in `dds.participant.logging.time_based_logging.process_received_message.timeout`.

The tracking ports can be configured using the property `dds.participant.logging.time_based_logging.process_received_message.tracked_ports`. The ports will be separated by a comma ','. They can be described using a regular expression, such as, "76\*,1234". If ports are not specified, all of the ports will be tracked.

The output message will look like this:

```
It took '0.003795' seconds to process the received message of '496' bytes by the port
'7662', which exceeds the threshold configured in 'dds.participant.logging.time_based_
logging.process_received_message.timeout'."
```

- **Authentication process (if using *RTI Security Plugins*):** Print a warning message when the authentication operation time exceeds the time threshold configured by the property

`dds.participant.logging.time_based_logging.authentication.timeout`. The output message will look like this:

```
[0xC0A87A01,0x00007BFC,0x00000001:0x000201C4{Entity=DR,MessageKind=DATA}|RECEIVE FROM
0xC0A87A01,0x00007BFC,0x00000002:0x000201C3]PRESParticipant_processHandshake:It took
'1.096696' seconds to authenticate the remote participant
[0xC0A87A01,0x00007BFC,0x00000002], which exceeds the threshold configured in
'dds.participant.logging.time_based_logging.authentication.timeout'.
```

These and other properties are documented in the [Property Reference Guide](#).

## 54.5 Logging a Backtrace for Failures

In some scenarios, it might be desirable to log the backtrace from the code. A backtrace is a list of the function calls that are currently active in a thread. You can usually inspect a backtrace by using debugging utilities like `gdb`, but sometimes these are not available.

Now, *Connex* logs the backtrace when a precondition fails in debug mode and when a segmentation fault occurs, for macOS, Windows, and Linux systems. The backtrace feature is automatically enabled upon creation of the first *DomainParticipant*. (That is, you will not see the backtrace log in a failure until the first *DomainParticipant* is created.)

- Normally when a precondition fails, the execution continues and there is no information about the problem, but *Connex* provides a backtrace with context about where the issue was.
- When a segmentation fault occurs, the processor or operating system does not always provide a core dump, but *Connex* provides a backtrace with context about where the issue was.

For Linux systems, the output of the backtrace will look like this:

```
#1 RTIOSapiProcessTester_testPrintBacktrace
/connexdds/osapi.1.0/srcC/process/test/processTester.c:638 [0x417371]
#2 RTITestSetting_runTestsExt /connexdds/test.1.0/srcC/setting/Setting.c:719 [0x4623B8]
#3 RTITestSetting_runTests /connexdds/test.1.0/srcC/setting/Setting.c:905 [0x462B85]
#4 RTIOSapiProcessTester_run /connexdds/osapi.1.0/srcC/process/test/processTester.c:683
[0x41750C]
#5 RTITestSetting_runTestsExt /connexdds/test.1.0/srcC/setting/Setting.c:719 [0x4623B8]
#6 RTITestSetting_runTests /connexdds/test.1.0/srcC/setting/Setting.c:905 [0x462B85]
#7 RTIOSapiTester_run /connexdds/osapi.1.0/srcC/test/Tester.c:128 [0x4039CB]
#8 main /connexdds/osapi.1.0/srcC/test/Tester.c:213 [0x403A65] #9 ?? ??:0 [0xE8434830] #10
_start ??? [0x403759]
```

See the [RTI Connex Core Libraries Platform Notes](#) for further details on enabling this feature on macOS, Windows, and Linux systems.

The backtrace feature is smart enough to log the backtrace only once for a given error and not for the following errors in the same code path of the caller's functions. For example, in the failure of the creation of the *DDSDomainParticipant*, *Connex* logs the backtrace for just one error instead of logging it for all of the error messages in the same code path:

```

U00007f86a87df700 Mx08:Udpv4SocketFactory.c:685:RTI0x2080010:invalid port 5562900

```

By default, the `print_format` `NDDS_CONFIG_LOG_PRINT_FORMAT_DEBUG` is set for the log level `NDDS_CONFIG_LOG_LEVEL_FATAL_ERROR`. This means that by default the backtrace is logged for precondition and segmentation faults; however, you can disable the backtrace for `NDDS_CONFIG_LOG_LEVEL_FATAL_ERROR`. In the following code, the log level `NDDS_CONFIG_LOG_LEVEL_FATAL_ERROR` uses the `print_format` `NDDS_CONFIG_LOG_PRINT_FORMAT_DEFAULT`, which does not contain the backtrace information:

```

NDDS_Config_Logger *logger = NDDS_Config_Logger_get_instance();
NDDS_Config_Logger_set_print_format_by_log_level(
    logger,
    NDDS_CONFIG_LOG_PRINT_FORMAT_DEFAULT,
    NDDS_CONFIG_LOG_LEVEL_FATAL_ERROR);

```

See [54.2.1 Format of Logged Messages on page 1092](#) and [54.2 Configuring Connex Logging on page 1089](#).

## 54.6 RTI Distributed Logger

*RTI Distributed Logger* is a library that enables applications to publish their log messages to *Connex*. The log message data can be visualized with *RTI Monitor* and *RTI Admin Console*. Since the data is provided in a *Topic*, you can also use *rtiddspy* or even write your own visualization tool.

Distributed Logger can also send *Connex* errors, warnings and other internal messages from its own builtin logging system as a DDS *Topic*. In fact, *Distributed Logger* provides a remote command topic so that its behavior can be remotely controlled at run time.

This section includes:

- [Using Distributed Logger in a Connex Application \(54.6.1 below\)](#)
- [Enabling Distributed Logger in RTI Services \(54.6.2 on page 1112\)](#)

## 54.6.1 Using Distributed Logger in a Connex Application

There are two ways to use *Distributed Logger*: directly through its API or by attaching it to an existing logging framework as an ‘appender’ or a ‘handler.’ Using the API directly is straightforward, but keep in mind that *Distributed Logger* is not intended to be a full-featured logging library. Rather, it is primarily intended to be integrated into third-party logging infrastructures.

The libraries that you will need for *Distributed Logger* are listed in [54.6.1.1 Distributed Logger Libraries below](#).

*Distributed Logger* comes with third-party integrations for the open-source project log4j (<http://logging.apache.org/log4j/>) as well as Java’s built-in logging library (`java.util.logging`). Please see [54.6.1.3 Examples on the next page](#) for examples that illustrate these integrations.

*Distributed Logger* captures and forwards *Connex* internal information, warning, and error messages using a DDS topic. It monitors these messages using the same mechanism as user log messages.

These *Connex* log messages are sent over DDS automatically as soon as you initialize *Distributed Logger* (by calling `RTI_DL_DistLogger_getInstance()` in C or C++, or `Logger.getLogger(...)` in Java; see the API Reference HTML documentation for details).

### 54.6.1.1 Distributed Logger Libraries

[Table 54.10 Required Libraries](#) lists the additional libraries you will need in order to use *Distributed Logger*.

**Table 54.10 Required Libraries**

Platform	Language	Static		Dynamic	
		Release	Debug	Release	Debug
Linux®	C	librtidlc.a	librtidlczd.a	librtidlc.so	librtidcd.so
	C++	librtidlc.a librtidlcppz.a	librtidlczd.a librtidlcppzd.a	librtidlc.so librtidlcpp.so	librtidcd.so librtidlcppd.so
	Java	N/A	N/A	distlog.jar distlogdatamodel.jar	distlogd.jar distlogdatamodeld.jar

- **c++/hello\_distributed\_logger**

This is a simple example of how to use the API directly and does not publish or subscribe any Topics except the ones related to *Distributed Logger*.

- **java/hello\_direct\_usage**

This is a simple example of how to use the API directly and does not publish or subscribe any Topics except the ones related to *Distributed Logger*.

- **java/hello\_file\_logger**

This example shows how an application can use the information provided by *Distributed Logger*. As the name suggests, this example subscribes to log messages and writes them to a file. Multiple DDS domains can be subscribed to simultaneously if desired. The example is meant to strike a balance between simplicity and function. Certainly more features could be added to make it a production-ready application but that would obscure the goal of the example.

- **java/hello\_java\_util\_logging**

In this example, all `System.{out/err}` invocations are replaced with Java logging library equivalents. It adds *Distributed Logger* through a configuration file.

- **java/hello\_log4j\_logging**

In this example, all `System.{out/err}` invocations are replaced with log4j library equivalents. It adds *Distributed Logger* through a configuration file.

Each example has a **README.txt** file which explains how to build and run it.

#### 54.6.1.4 Data Type Resource

You can find the data types used by *Distributed Logger* in `<NDDSHOME>/resource/idl/distog.idl`. (See [Paths Mentioned in Documentation on page 1](#).)

If you want to generate code and interact with *Distributed Logger* through Topics, you can use this file to do so. You will need to provide extra command-line arguments to *RTI Code Generator* (`rtiddsgen`). (This allows us to accommodate multiple language bindings within the same file. As a consequence, we've used preprocessor definitions to achieve this functionality.) The command-line options which must be added to `rtiddsgen` are as follows:

- For C or C++: **-D LANGUAGE\_C**
- For Java: **-D LANGUAGE\_JAVA**
- For .Net: **-D LANGUAGE\_DOTNET**

If you plan to use the generated code in your application (to subscribe to log messages, for instance) be aware that the type names used might not match the default ones. *Do not* use the generated type names obtained when calling `get_type_name()` or found in `distlogSupport.h`. Use the variables in [Table 54.11 Registration Names for each Distributed Logger Type](#) instead.

**Table 54.11 Registration Names for each Distributed Logger Type**

Type	Registered Typename	Variable
Log Message	<code>com::rti::dl::LogMessage</code>	C/C++: RTI_DL_LOG_MESSAGE_TYPE_NAME Java: LOG_MESSAGE_TYPE_NAME.VALUE
Administration State	<code>com::rti::dl::admin::State</code>	C/C++: RTI_DL_STATE_TYPE_NAME Java: STATE_TYPE_NAME.VALUE
Administration Command Request	<code>com::rti::dl::admin::CommandRequest</code>	C/C++: RTI_DL_COMMAND_REQUEST_TYPE_NAME Java: COMMAND_REQUEST_TYPE_NAME.VALUE
Administration Command Response	<code>com::rti::dl::admin::CommandResponse</code>	C/C++: RTI_DL_COMMAND_RESPONSE_TYPE_NAME Java: COMMAND_RESPONSE_TYPE_NAME.VALUE

For instance, to subscribe to log messages in C you will need to do the following:

```
retcode = RTI_DL_LogMessageTypeSupport_register_type(
    participant, RTI_DL_LOG_MESSAGE_TYPE_NAME);
```

### 54.6.1.5 Distributed Logger Topics

*Distributed Logger* uses four Topics to publish log messages, state, and command responses and one topic to subscribe to command requests. These are detailed in [Table 54.12 Topics Used by Distributed Logger](#).

**Table 54.12 Topics Used by Distributed Logger**

Topic	Type Name	Quality of Service
<code>rti/distlog</code>	<code>com::rti::dl::LogMessage</code>	Reliable Transient Local
<code>rti/distlog/administration/state</code>	<code>com::rti::dl::admin::State</code>	Reliable Transient Local

Table 54.12 Topics Used by Distributed Logger

rti/distlog/administration/command_request	com::rti::dl::admin::CommandRequest	Reliable
rti/distlog/administration/command_response	com::rti::dl::admin::CommandResponse	Reliable

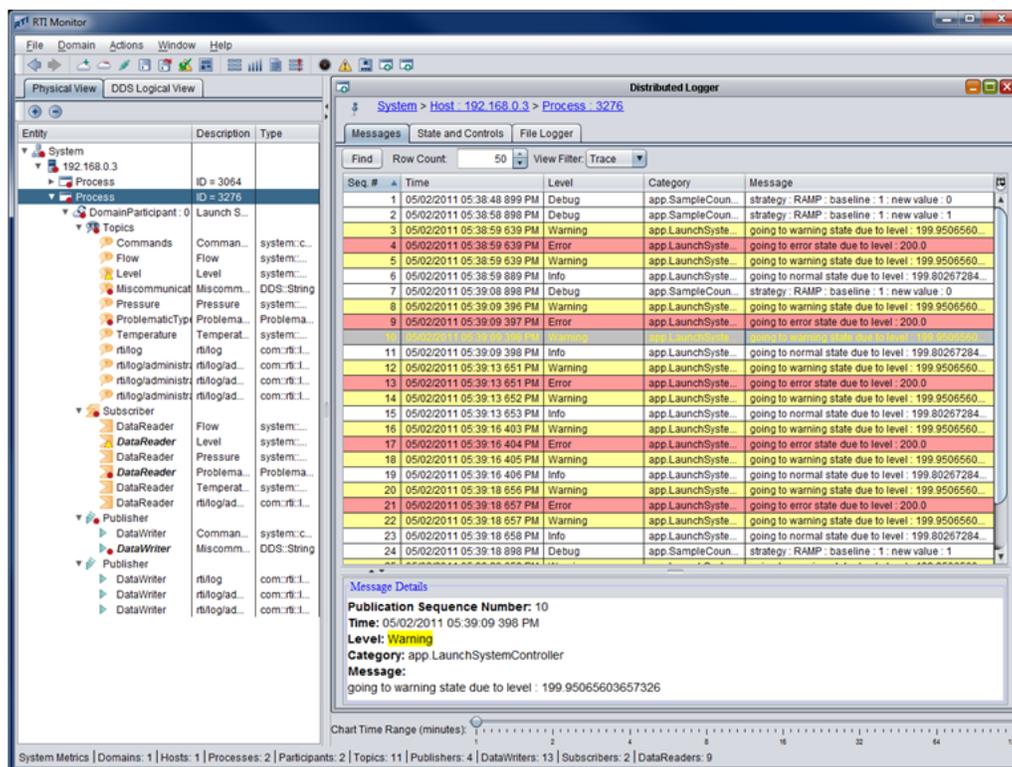

### 54.6.1.6 Distributed Logger IDL

The IDL describing the types used for Topics created by *Distributed Logger* are in `<NDDSHOME>/resource/idl/distlog.idl`. (See [Paths Mentioned in Documentation on page 1](#).) You can use this IDL to create custom applications that use the data provided by *Distributed Logger* and/or to remotely control any *Distributed Logger* instances that are running in your system. The IDL has been designed to take advantage of the latest type-support features in *Connex*.

### 54.6.1.7 Viewing Log Messages

One way to see the messages from *Distributed Logger* is to use *RTI Monitor*.

Figure 54.1: Viewing Log Messages with RTI Monitor

Other ways to see the log messages include using *rtiddspy* or writing your own visualization tool. If you want to write your own application that interacts with *Distributed Logger*, you can find the IDL in `<NDDSHOME>/resource/idl/distlog.idl`. (See [Paths Mentioned in Documentation on page 1](#).)

### 54.6.1.8 Logging Levels

Log levels in *Distributed Logger* are organized as shown in [Table 54.13 Mapping between Distributed Logger and Connex Builtin Logging System](#) (ordered by importance). This table also shows the mapping between logging levels in the *Connex* builtin logging system and *Distributed Logger*.

**Table 54.13 Mapping between Distributed Logger and Connex Builtin Logging System**

Connex Builtin Logging System Log Level	Distributed Logger Log Level
NDDS_CONFIG_LOG_FATAL_ERROR	RTI_DL_FATAL_LEVEL
NDDS_CONFIG_LOG_LEVEL_ERROR	RTI_DL_ERROR_LEVEL
NDDS_CONFIG_LOG_LEVEL_WARNING	RTI_DL_WARNING_LEVEL
NDDS_CONFIG_LOG_LEVEL_STATUS_LOCAL	RTI_DL_NOTICE_LEVEL
NDDS_CONFIG_LOG_LEVEL_STATUS_REMOTE	RTI_DL_INFO_LEVEL
NDDS_CONFIG_LOG_LEVEL_DEBUG	RTI_DL_DEBUG_LEVEL

### 54.6.1.9 Distributed Logger Quality of Service Settings

To ensure that *Distributed Logger* works correctly with other RTI tools, some QoS settings are hard-coded and cannot be modified by customized profiles. [Table 54.14 QoS Values Used by Distributed Logger](#) lists the QoS values that are set in *Distributed Logger*. Values in bold are hard-coded; therefore even if they appear in an XML profile, they remain as noted in the table.

**Table 54.14 QoS Values Used by Distributed Logger**

Entity	Property	Value
Subscriber	<b>Presentation.access_scope</b>	<b>PRES_INSTANCE_PRESENTATION_QOS</b>
	<b>Presentation.coherent_access</b>	<b>false</b>
	<b>Presentation.ordered_access</b>	<b>false</b>
Publisher	<b>Presentation.access_scope</b>	<b>PRES_INSTANCE_PRESENTATION_QOS</b>
	<b>Presentation.coherent_access</b>	<b>false</b>
	<b>Presentation.ordered_access</b>	<b>false</b>
Log Message Topic	<b>Reliability.kind</b>	<b>DDS_RELIABLE_RELIABILITY_QOS</b>
	<b>Durability.kind</b>	<b>DDS_TRANSIENT_LOCAL_DURABILITY_QOS</b>
Administration State Topic	<b>Reliability.kind</b>	<b>DDS_RELIABLE_RELIABILITY_QOS</b>
	<b>Durability.kind</b>	<b>DDS_TRANSIENT_LOCAL_DURABILITY_QOS</b>

Table 54.14 QoS Values Used by Distributed Logger

Entity	Property	Value
Administration Command Request Topic	Reliability.kind	DDS_RELIABLE_RELIABILITY_QOS
Administration Command Response Topic	Reliability.kind	DDS_RELIABLE_RELIABILITY_QOS
Log Message DataWriter	Ownership.kind	DDS_SHARED_OWNERSHIP_QOS

### 54.6.1.10 Troubleshooting Logging

#### 54.6.1.10.1 Message Losses

In some cases, some of the messages logged with *Distributed Logger* can be lost, especially when the log message generation rate is high.

You can detect losses by inspecting the **LogMessage.messageId** field when subscribing to log messages. If the difference between two consecutive log messages coming from the same **LogMessage.hostAndAppId** is greater than 1, then some messages were lost.

Messages can be lost for two reasons:

- The queue that *Distributed Logger* uses to temporarily store log messages from the application until they can be written to *Connex* is full.
- A log message published by *Distributed Logger* is replaced on the *Connex DataWriter* queue before the *DataReaders* have a chance to receive it.

To minimize losses in the *Distributed Logger* queue, increase the queue size by using the API `RTI_DLOptions::setQueueSize`.

To minimize losses in the *DataWriter* that publishes the log messages, increase the number of messages that the *DataWriter* is caching for the process where *Distributed Logger* is running. To increase this number, configure `writer_qos.history.depth`. You can change the history depth in the QoS profile that you use to configure *Distributed Logger*, by invoking the APIs `RTI_DLOptions::setQosLibrary` and `RTI_DLOptions::setQosProfile`.

#### 54.6.1.10.2 Logger Device not Working

If you enable *Distributed Logger*, any previously created logger device will not be used. This is because you cannot have more than one logger device installed. When you enable *Distributed Logger*, it overwrites any previously created logger device.

Suppose *Distributed Logger* is enabled, and you are using a profile that configures *Connex* to print the log messages to a file, such as:

```
<qos_profile name="..." is_default_qos="true">
  <participant_factory_qos>
    <logging>
      <output_file>/path/to/log/file/log.txt</output_file>
    </logging>
  </participant_factory_qos>
  ...
```

In this case, messages will be printed by *Distributed Logger*, they will not be sent to the log file.

If you want messages to be printed to the log file, you need to disable *Distributed Logger* first.

## 54.6.2 Enabling Distributed Logger in RTI Services

Many RTI components provide integrated support for *Distributed Logger* (check the component's *Release Notes*) and include the *Distributed Logger* library in their distribution. To enable *Distributed Logger* in these components, modify their XML configuration file. In the `<administration>` section, add the `<distributed_logger>` tag as shown in this example:

```
<persistence_service name="default">
  <administration>
    <domain_id>10</domain_id>
    <distributed_logger>
      <enabled>true</enabled>
      <filter_level>DEBUG</filter_level>
      <queue_size>2048</queue_size>
```

```
<thread>
  <priority>
    THREAD_PRIORITY_BELOW_NORMAL
  </priority>
  <stack_size>8192</stack_size>
  <cpu_list>
    <element>0</element>
    <element>1</element>
  </cpu_list>
  <cpu_rotation>
    THREAD_SETTINGS_CPU_NO_ROTATION
  </cpu_rotation>
</thread>
  </distributed_logger>
</administration>
...
</persistence_service>
```

The tags supported within the `<distributed_logger>` tag are described in [Table 54.15 Distributed Logger Tags](#).

Table 54.15 Distributed Logger Tags

Tags within <distributed_ logger>	Description	Number of Tags Allowed
<enabled>	Controls whether or not <i>Distributed Logger</i> should be enabled at start up. This field is required. Allowed values: TRUE or FALSE	1 (required)
<filter_level>	<p>The filter level for the log messages to be sent. <i>Distributed Logger</i> uses the filter level to discard log messages before they can be sent from the application/service. This is the minimum log level that will be sent out over the network. For example, when using the NOTICE level, any INFO, DEBUG and TRACE-level log messages will be filtered out and not sent from the application/service to <i>Connex</i>.</p> <div style="border: 1px solid black; background-color: #ffffcc; padding: 5px; margin: 10px 0;"> <p>See important information in <a href="#">A service's verbosity influences the way the log messages reach Distributed Logger and their quantity</a>. If a service (such as RTI Persistence Service, RTI Routing Service, or another service that is integrated with Distributed Logger) is configured with a low verbosity, it will not pass a lot of messages to Distributed Logger, even if the Distributed Logger filter level is set to a very verbose one (such as TRACE). On the contrary, a high verbosity will work better, because it will pass more messages to Distributed Logger; in this case the filter level will have more effect. on the next page.</p> </div> <p>Can be set to these values:</p> <ul style="list-style-type: none"> <li>• SILENT</li> <li>• FATAL</li> <li>• SEVERE</li> <li>• ERROR</li> <li>• WARNING</li> <li>• NOTICE</li> <li>• INFO</li> <li>• DEBUG</li> <li>• TRACE (most verbose level, default)</li> </ul>	0 or 1
<queue_size>	The size of an internal message queue used to store log messages before they are written to DDS. Default, 128 log messages.	0 or 1
<echo_to_stdout>	Controls whether or not Distributed Logger should echo log messages to standard output (true) or not (false). Allowed values: TRUE or FALSE Default: TRUE	0 or 1
<log_infrastructure_messages>	Controls whether or not Distributed Logger should log infrastructure messages Allowed values: TRUE or FALSE Default: TRUE	0 or 1
<thread>	See <a href="#">Table 54.16 Distributed Logger Thread Tags</a> .	0 or 1

Table 54.16 Distributed Logger Thread Tags

Tags within <distributed_logger>/ <thread>	Description	Number of Tags Allowed
<cpu_list>	<p>Each <b>&lt;element&gt;</b> specifies a processor on which the Distributed Logger thread may run.</p> <pre>&lt;cpu_list&gt;   &lt;element&gt;value&lt;/element&gt; &lt;/cpu_list&gt;</pre> <p>Only applies to platforms that support controlling CPU core affinity (see the <a href="#">RTI Connex Core Libraries Platform Notes</a>).</p>	0 or 1
<cpu_rotation>	<p>Determines how the CPUs in <b>&lt;cpu_list&gt;</b> will be used by the Distributed Logger thread. The value can be either:</p> <ul style="list-style-type: none"> <li>• <code>THREAD_SETTINGS_CPU_NO_ROTATION</code> The thread can run on any listed processor, as determined by OS scheduling.</li> <li>• <code>THREAD_SETTINGS_CPU_RR_ROTATION</code> The thread will be assigned a CPU from the list in round-robin order.</li> </ul> <p>Only applies to platforms that support controlling CPU core affinity (see the <a href="#">RTI Connex Core Libraries Platform Notes</a>).</p>	0 or 1
<mask>	<p>A collection of flags used to configure threads of execution. Not all of these options may be relevant for all operating systems. May include these bits:</p> <ul style="list-style-type: none"> <li>• <code>STDIO</code></li> <li>• <code>FLOATING_POINT</code></li> <li>• <code>REALTIME_PRIORITY</code></li> <li>• <code>PRIORITY_ENFORCE</code></li> </ul> <p>It can also be set to a combination of the above bits by using the “or” symbol (<code> </code>), such as <code>STDIO FLOATING_POINT</code>.</p> <p>Default: <code>MASK_DEFAULT</code></p>	0 or 1
<priority>	<p>Thread priority. The value can be specified as an unsigned integer or one of the following strings.</p> <ul style="list-style-type: none"> <li>• <code>THREAD_PRIORITY_DEFAULT</code></li> <li>• <code>THREAD_PRIORITY_HIGH</code></li> <li>• <code>THREAD_PRIORITY_ABOVE_NORMAL</code></li> <li>• <code>THREAD_PRIORITY_NORMAL</code></li> <li>• <code>THREAD_PRIORITY_BELOW_NORMAL</code></li> <li>• <code>THREAD_PRIORITY_LOW</code></li> </ul> <p>When using an unsigned integer, the allowed range is platform-dependent.</p>	0 or 1
<stack_size>	<p>Thread stack size, specified as an unsigned integer or set to the string <code>THREAD_STACK_SIZE_DEFAULT</code>. The allowed range is platform-dependent.</p>	0 or 1

### 54.6.2.1 Relationship Between Service Verbosity and Filter Level

A service’s verbosity influences the way the log messages reach *Distributed Logger* and their quantity. If a service (such as *RTI Persistence Service*, *RTI Routing Service*, or another service that is integrated

with *Distributed Logger*) is configured with a low verbosity, it will not pass a lot of messages to *Distributed Logger*, even if the *Distributed Logger* filter level is set to a very verbose one (such as TRACE). On the contrary, a high verbosity will work better, because it will pass more messages to *Distributed Logger*; in this case the filter level will have more effect.

**Note:** Since *Distributed Logger* uses a separate thread to send log messages, there is little impact on performance with more verbose filter levels. However, there is some performance penalty in services that use a higher verbosity.

# Chapter 55 Troubleshooting Discovery

To understand the flow of messages during discovery, you can increase the verbosity of the messages logged by *Connex* so that you will see whenever a new entity is discovered, and whenever there is a match between a local entity and a remote entity.

This can be achieved with the logging API:

```
NDDConfigLogger::get_instance()->set_verbosity_by_category (NDDS_CONFIG_LOG_CATEGORY_ENTITIES, NDDS_CONFIG_LOG_VERBOSITY_STATUS_REMOTE);
```

Using the scenario in the summary diagram in [25.3 Discovery Traffic Summary](#) on page 346, these are the messages as seen on DomainParticipant A:

```
[D0049|ENABLE]DISCPluginManager_onAfterLocalParticipantEnabled:announcing new local participant: 0XA0A01A1,0X5522,0X1,0X1C1
[D0049|ENABLE]DISCPluginManager_onAfterLocalParticipantEnabled:at {46c614d9,0C43B2DC}
```

(The above messages mean: First participant A DATA sent out when participant A is enabled.)

```
DISCSimpleParticipantDiscoveryPluginReaderListener_onDataAvailable:discovered new participant: host=0x0A0A01A1, app=0x0000552B, instance=0x00000001
DISCSimpleParticipantDiscoveryPluginReaderListener_onDataAvailable:at {46c614dd,8FA13C1F}
DISCParticipantDiscoveryPlugin_assertRemoteParticipant:plugin discovered/updated remote participant: 0XA0A01A1,0X552B,0X1,0X1C1
DISCParticipantDiscoveryPlugin_assertRemoteParticipant:at {46c614dd,8FACE677}
DISCParticipantDiscoveryPlugin_assertRemoteParticipant:plugin accepted new remote participant: 0XA0A01A1,0X552B,0X1,0X1C1
DISCParticipantDiscoveryPlugin_assertRemoteParticipant:at {46c614dd,8FACE677}
```

(The above messages mean: Received participant B DATA.)

```
DISCSimpleParticipantDiscoveryPlugin_remoteParticipantDiscovered:re-announcing participant self: 0XA0A01A1,0X5522,0X1,0X1C1
DISCSimpleParticipantDiscoveryPlugin_remoteParticipantDiscovered:at {46c614dd,8FC02AF7}
```

(The above messages mean: Resending participant A DATA to the newly discovered remote participant.)

```

PRESPPsService_linkToLocalReader:assert remote 0XA0A01A1,0X552B,0X1,0X200C2, local 0x000200C7
in reliable reader service

DISCParticipantDiscoveryPlugin_removeRemoteParticipantI:plugin discovered disposed remote
participant: 0XA0A01A1,0X552B,0X1,0X1C1
DISCParticipantDiscoveryPlugin_removeRemoteParticipantI:at {46c61501,28E68E3D}
DISCParticipantDiscoveryPlugin_removeRemoteParticipantI:remote entity removed from database:
0XA0A01A1,0X552B,0X1,0X1C1
DISCParticipantDiscoveryPlugin_removeRemoteParticipantI:at {46c61501,28E68E3D}
```

(The above messages mean: Removing discovered entities from local database, before shutting down.)

As you can see, the messages are encoded, since they are primarily used by RTI support personnel.

For more information on the message logging API, see [54.2 Configuring ConnexT Logging on page 1089](#).

If you notice that a remote entity is not being discovered, check the QoS related to discovery (see [25.4 Discovery-Related QoS on page 346](#)).

If a remote entity is discovered, but does not match with a local entity as expected, check the QoS of both the remote and local entity.

# Chapter 56 Heap Memory Monitoring

*Connex*t allows you to monitor the memory allocations done by the middleware on the native heap. This feature can be used to analyze and debug unexpected memory growth.

This feature includes the following APIs (available in all languages):

- **NDDSUtilityHeapMonitoring::enable**
- **NDDSUtilityHeapMonitoring::disable**
- **NDDSUtilityHeapMonitoring::pause**
- **NDDSUtilityHeapMonitoring::resume**
- **NDDSUtilityHeapMonitoring::take\_heap\_snapshot**

After **NDDSUtilityHeapMonitoring::enable** is called, you may invoke **NDDSUtilityHeapMonitoring::take\_heap\_snapshot** to save the current heap memory usage to a file. By comparing two snapshots, you can tell if new memory has been allocated and, in many cases, where.

For more information, see the API Reference HTML documentation (select **Modules > RTI Connex**t API Reference > **General Utilities > Heap Monitoring**).

# Chapter 57 Discovery Snapshots

*Connex* allows you to take discovery snapshots of *DomainParticipants*, *DataWriters*, and *DataReaders*. Discovery snapshots are useful when your applications are not communicating as expected. *DomainParticipant* discovery snapshots show you useful information about the discovery status between *DomainParticipants*; *DataWriter* discovery snapshots show information about matched *DataReaders*; and *DataReader* discovery snapshots show information about their matched *DataWriters*. These snapshots show the information present at the time the functions are called to take them.

## 57.1 Viewing the Discovery Status

For local *DomainParticipants*, a discovery snapshot includes information about themselves and discovered remote ones, such as the domain, entity and role names, GUID prefixes, locators, and security-related information. An example of the output is as follows:

```
-----  
-----  
Participant guid="0x0101F2F1,0xC229B376,0x46572559:0x00000000"  
domain_id=0 name="participantTestName" role="participantTestRole"  
-----  
Matched Participants:  
-----  
guid="0x0101D75E,0xB70D1850,0x2B0D229B:0x00000000"  
name="participantTestName" role="participantTestRole"  
unicastLocators="udpv4://10.70.2.68:7413"  
shmem://CA1B:28DA:1E18:F955:3727:3AFE:0000:0000:7413"  
-----  
-----
```

For local *DataWriters/DataReaders*, a discovery snapshot includes information about themselves and matched/unmatched remote *DataReaders/DataWriters*. A local *DataWriter/DataReader* will match with a remote *DataReader/DataWriter* if its *Topic*, type, and QoS are compatible with the remote entity. A remote *DataWriter/DataReader* will unmatch with the local *DataReader/DataWriter* (even if it uses the same *Topic*) if its QoS is incompatible with the local *DataReader/DataWriter* or if security-related reasons make it incompatible. The

discovery snapshot shows information about the remote entity, including the domain, entity names, GUIDs, *Topic*, type, local and remote entity kinds, locators, liveness information, and, if the remote entity is incompatible with the local one, the reason why. Some examples of the snapshot output are the following:

For *DataWriters*:

```
-----
-----
Writer guid="0x0101F926,0xBE2B43E8,0x3CF1676B:0x80000003"
domain_id=0 topic="FooTopic" type="FooType" type="false"
name="writer1TestName"
-----
Matched Readers:
-----
guid="0x0101588A,0x532B8256,0xFAAB0F1E:0x80000004"
name="reader1TestName" unicastLocators="udp4://10.70.2.68:7411
udp4://10.70.1.159:7411
shmem://CA1B:28DA:1E18:F955:3727:3AFE:0000:0000:7411"
status="ALIVE"
-----
-----
Not matched Readers (on the same Topic):
-----
guid="0x0101588A,0x532B8256,0xFAAB0F1E:0x80000104"
name="reader2TestName" unicastLocators="udp4://10.70.2.68:7411
udp4://10.70.1.159:7411
shmem://CA1B:28DA:1E18:F955:3727:3AFE:0000:0000:7411"
incompatibility="QoS"
-----
-----
```

For *DataReaders*:

```
-----
-----
Reader guid="0x010101D1,0xE6695CC6,0xFC4999A6:0x80000004" domain_id=0
topic="FooTopic" type="FooType" keyed_type="false" name="reader1TestName"
-----
Matched Writers:
-----
guid="0x0101DE39,0x0E87C1C7,0x78039363:0x80000003" name="writer1TestName"
unicastLocators="udp4://10.70.2.68:7413
shmem://CA1B:28DA:1E18:F955:3727:3AFE:0000:0000:7413" status="ALIVE"
-----
guid="0x0101DE39,0x0E87C1C7,0x78039363:0x80002103" name="writer2TestName"
unicastLocators="udp4://10.70.2.68:7413
shmem://CA1B:28DA:1E18:F955:3727:3AFE:0000:0000:7413" status="ALIVE"
-----
-----
Not matched Writers (on the same Topic):
-----
-----
```

This feature is available through the following APIs (in all languages):

- **take\_snapshot(dds::domain::DomainParticipant participant)**
- **take\_snapshot(dds::pub::DataWriter writer)**
- **take\_snapshot(dds::sub::DataReader reader)**

For more information, see the API Reference HTML documentation.

## 57.2 Using Snapshots to Debug the Discovery Process

Imagine two participants in your network, Participant1 and Participant2. Participant1 has a *DataWriter*, Participant2 has a *DataReader*. You execute the two participants, but the *DataReader* is not receiving data from the *DataWriter*. To determine whether it is a discovery issue, use the discovery snapshot feature.

- **Check if Participant1 and Participant2 are discovering each other.** Take a *DomainParticipant* discovery snapshot on either the Participant1 or Participant2 side. For example, if you take a snapshot of the discovery information of Participant1, look for Participant2 in the output table. If it is there, you know that Participant1 and Participant2 are discovered on both sides, so the issue is not related to participant discovery. If Participant2 does not appear in the snapshot, check the domainId and partition on both sides, to see if they are the same; check that the locators on both sides are reachable.
- **Check if the *DataWriter* and *DataReader* are compatible.** Once you know that the participants have successfully discovered each other, check why the *DataWriter* and *DataReader* are not communicating. Take a *DataWriter/DataReader* snapshot on either side. For example, if you take a snapshot of the discovery information of the *DataWriter*, look for the *DataReader* in it. If the *DataReader* is not there, then you know that the *DataWriter* and *DataReader* do not match. Check the compatibility of the entities' *Topic*, type, and entity kind. If the *DataReader* is in the *DataWriter* discovery snapshot, but labeled not matched (but in the same *Topic*), check the incompatibility reason provided by the snapshot.

Discovery snapshots give you enough information to fix discovery issues and have communication between the endpoints (*DataWriters* and *DataReaders*).

**Note:** If you take a discovery snapshot in the middle of the discovery process, there is a small chance you will get an error that looks like “Failed to take participant discovery snapshot. Please try to take the snapshot later when the discovery process is more advanced”. This error appears because of the way *Connex* takes snapshots; it needs some stability in discovery registers during the process. If you get this error, execute the snapshot again, until the error goes away. If the error persists, take the snapshot later when the discovery process is more advanced. You will not get this error once the discovery process is finished.

# Chapter 58 Network Capture

*Connex* allows you to capture network traffic that one or more *DomainParticipants* send or receive. This feature can be used to analyze and debug communication problems between your DDS applications. When network capture is enabled, each *DomainParticipant* will generate a pcap-based file that can then be opened by a packet analyzer like Wireshark, provided the right dissectors are installed.

To some extent, network capture can be used as an alternative to existing pcap-based network capture software (such as Wireshark). This will be the case when you are only interested in analyzing the traffic a *DomainParticipant* sends/receives. In this scenario, network capture will actually have some advantages over more general pcap-based network capture applications: RTI's network capture includes additional information, such as security-related data; it also removes information that is not needed, such as user data, when you want to reduce the capture size. That said, RTI's network capture is not a replacement for other pcap-based network capture applications: it only captures the traffic exchanged by the *DomainParticipants*, but it does not capture any other traffic exchanged through the system network interfaces.

To capture network traffic, **NDDSUtilityNetworkCapture::enable** must be invoked before creating any *DomainParticipant*. Similarly, **NDDSUtilityNetworkCapture::disable** must be called after deleting all participants. In between these calls, you may start, stop, pause, or resume capturing traffic for one or all *DomainParticipants*.

This feature includes the following APIs (available in all languages):

- **NDDSUtilityNetworkCapture::enable**
- **NDDSUtilityNetworkCapture::disable**
- **NDDSUtilityNetworkCapture::start**
- **NDDSUtilityNetworkCapture::stop**
- **NDDSUtilityNetworkCapture::pause**
- **NDDSUtilityNetworkCapture::resume**

For more information, see the API Reference HTML documentation.

## 58.1 Capturing Shared Memory Traffic

Every RTPS frame in network capture has a source and a destination associated with it. In the case of shared memory traffic, a process identifier and a port determine the source and destination endpoints.

Access to the process identifier (PID) of the source for inbound traffic requires changes in the shared memory segments. These changes would break shared memory compatibility with versions of *Connex* earlier than 6.1.0. For this reason, by default, network capture will not populate the value of the source PID for inbound shared memory traffic.

If interoperability with pre-6.1.0 versions of *Connex* is not necessary, you can generate capture files containing the source PID for inbound traffic. To do so, configure the value of the **dds.transport.minimum\_compatibility\_version** property to 6.1.0. (See [47.19 PROPERTY QosPolicy \(DDS Extension\)](#) on page 837.)

```
<domain_participant_qos>
  <property>
    <value>
      <element>
        <name>dds.transport.minimum_compatibility_version</name>
        <value>6.1.0</value>
        <propagate>false</propagate>
      </element>
    </value>
  </property>
</domain_participant_qos>
```

This property is never propagated, so it must be consistently configured throughout the whole system.

**Note:** Changing the value of this property affects the type of shared memory segments that *Connex* uses. For that reason, you may see the following warning, resulting from leftover shared memory segments:

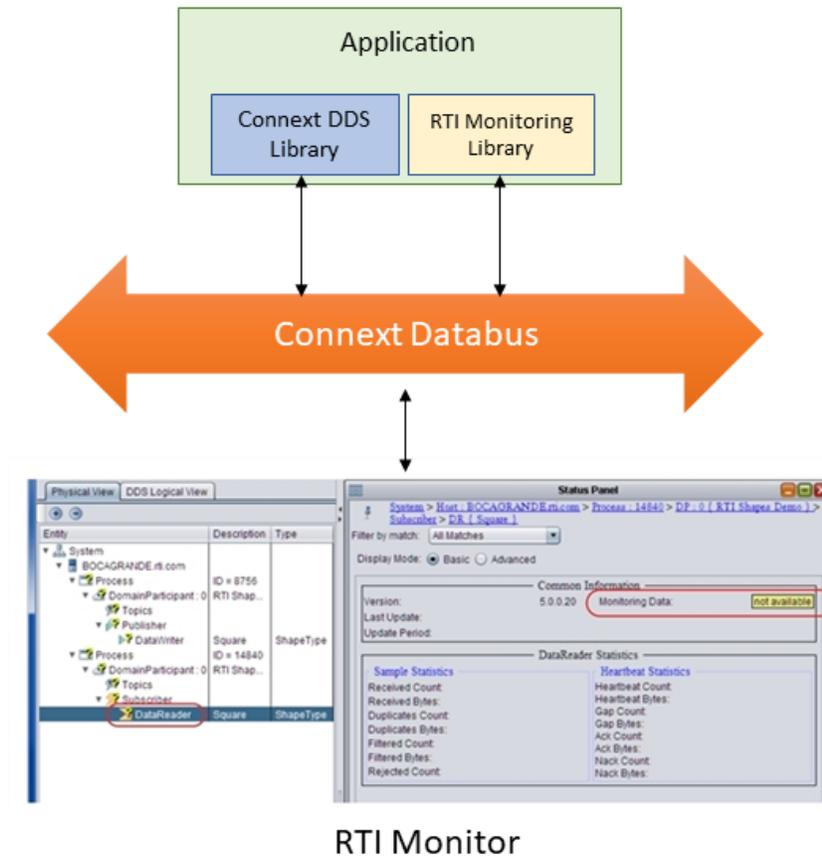

```
[0xC733A001,0xB248F671,0xAEC4A0C1:0x000001C1{Domain=200}|CREATE DP|ENABLE] NDDS_
Transport_Shmem_is_segment_compatible:incompatible shared memory protocol detected.
Current version 4.0 not compatible with 2.0.
```

The leftover shared memory segments can be removed using the **ipcrm** command. See <https://community.rti.com/kb/what-are-possible-solutions-common-shared-memory-issues> for more information.

## Chapter 59 RTI Monitoring Library

*RTI Monitoring Library* is a plug-in that enables *Connex*t applications to provide monitoring data. The monitoring data can be visualized with *RTI Monitor*, a separate GUI application that can run on the same host as *Monitoring Library* or on a different host.

*Connex*t notifies *Monitoring Library* every time an entity is created/deleted or a QoS is changed. *Monitoring Library* periodically queries the status of all *Connex*t entities. You can enable/disable monitoring by setting values in the *DomainParticipant's* *PropertyQoSPolicy* (programmatically or through an XML QoS profile).

This section of the *User's Manual* includes:

## 59.1 Enabling Monitoring in Your Application

There are two ways to enable monitoring in your application:

- 59.1.1 Method 1—Change the Participant QoS to Automatically Load the Dynamic Monitoring Library on the next page
- 59.1.2 Method 2—Change the Participant QoS to Specify the Monitoring Library Create Function Pointer and Explicitly Load the Monitoring Library on page 1129

### Notes:

- The libraries that you will need for Monitoring are listed in the [RTI Connex Core Libraries Platform Notes](#).

- If your original application has made modifications to the ParticipantQoS `resource_limits.type_code_max_serialized_length`, `ParticipantQoS resource_limits.type_object_max_serialized_length`, or any of the transport's default settings to enable large type code or large data, refer to [59.3 What Monitoring Topics are Published? on page 1134](#) for additional QoS modifications that may be needed.
- *Monitoring Library* creates internal *DataWriters* to publish monitoring data by making modifications based on the default *DataWriter* QoS settings. If you have made changes to the default *DataWriter* QoS, especially if you have increased/decreased the initial or maximum DDS sample/instance values, *Monitoring Library* may have trouble creating *DataWriters* to publish monitoring data, or it may limit the number of statistics that you can publish through the internal monitoring writers. If this is true for your case, you may want to specify the `qos_library` and `qos_profile` that will be used to create these internal writers for publishing monitoring data, to avoid being impacted by default *DataWriter* QoS settings. See [Configuring Monitoring Library \(59.5 on page 1136\)](#) for details.

### 59.1.1 Method 1—Change the Participant QoS to Automatically Load the Dynamic Monitoring Library

If **all of the following are true**, you can enable monitoring simply by changing your participant QoS (otherwise, use [59.1.2 Method 2—Change the Participant QoS to Specify the Monitoring Library Create Function Pointer and Explicitly Load the Monitoring Library on the next page](#)):

- Your application is linked to *dynamic Connex*t libraries or you are using Java or .Net, and
- You will not be running your application on INTEGRITY (which doesn't support this), and
- You are NOT linking in an additional monitoring library into your application at link time (you let the middleware load the monitoring library for you automatically as needed).

If you change the QoS in an XML file as shown below, you can enable/disable monitoring without recompiling. If you change the QoS in your source code, you may need to recompile every time you enable/disable monitoring.

If you need to change the participant QoS by hand, refer to the definition of **Built-inQosLib::Generic.Monitoring.Common** in `<NDDSHOME>/resource/xml/BuiltinProfiles.documentationONLY.xml` for the values you should set.

Example XML to enable monitoring:

```
<domain_participant_qos>
  <property>
    <value>
      <element>
        <name>rti.monitor.library</name>
        <value>rtimonitoring</value>
      </element>
    </value>
  </property>
</domain_participant_qos>
```

```
<name>rti.monitor.create_function</name>
  <value>RTIDefaultMonitor_create</value>
</element>
</value>
</property>
</domain_participant_qos>
```

**Note:** Do not mix static and dynamic libraries; see Building Applications chapter in the [RTI Connex Core Libraries Platform Notes](#) .

### 59.1.2 Method 2—Change the Participant QoS to Specify the Monitoring Library Create Function Pointer and Explicitly Load the Monitoring Library

If **any** of the following are true, you must change the Participant QoS to enable monitoring and explicitly load the correct version of *Monitoring Library* at compile time:

- Your application is linked to the *static* version of *Connex* libraries.
- You will run your application on an INTEGRITY platform.
- You want to explicitly link in the monitoring library (static or dynamic) into your application.

There are two ways to do this:

- [59.1.2.0.1 Method 2-A: Change the Participant QoS by Specifying the Monitoring Library Create Function Pointer in Source Code on the next page](#): Applies to most users who cannot use Method 1 and do not mind changing/recompiling source code every time you enable/disable monitoring, or whose system does not support setting environment variables programmatically. Participant QoS must be defined in source code with this approach.
- [59.1.2.0.2 Method 2-B: Change the Participant QoS by Specifying the Monitoring Library Create Function Pointer in an Environment Variable on page 1133](#): Applies to users who cannot use Method 1 *and* want to specify the create function pointer via an environment variable. This approach allows the Participant QoS to be defined in an XML file or in source code.

**Note:** Do not mix static and dynamic libraries; see Building Applications chapter in the [RTI Connex Core Libraries Platform Notes](#) .

**59.1.2.0.1 Method 2-A: Change the Participant QoS by Specifying the Monitoring Library Create Function Pointer in Source Code**

1. Modify your *Connex*t application based on the following examples.

**Traditional C++ Example:**

```
#include "ndds/ndds_cpp.h"
#include "monitor/monitor_common.h"
extern "C" int publisher_main(int domainId, int sample_count)
{
    ...
    DDSDomainParticipant *participant = NULL;
    DDS_DomainParticipantQos participant_qos;

    /* Get default QoS */
    retcode =
    DDSTheParticipantFactory->get_default_participant_qos(
        participant_qos);
    if (retcode != DDS_RETCODE_OK) {
        /*Error*/
    }
    /* This property indicates that the DomainParticipant
       has monitoring turned on. The property name MUST be
       "rti.monitor.library". The value can be anything.*/
    retcode = DDSPropertyQosPolicyHelper::add_property(
    participant_qos.property,
    "rti.monitor.library", "rtimonitoring", DDS_BOOLEAN_FALSE);
    if (retcode != DDS_RETCODE_OK) {
        /*Error*/
    }
    /* The property name "rti.monitor.create_function"
       indicates the entry point for the monitoring library.
       The value MUST be the value of the function pointer of
       RTIDefaultMonitor_create */

    retcode = DDSPropertyQosPolicyHelper::add_pointer_property(
        participant_qos.property,
        "rti.monitor.create_function_ptr",
        (void *) RTIDefaultMonitor_create);
    if (retcode != DDS_RETCODE_OK) {
        /* Error */
    }
    /* Create DomainParticipant with participant_qos */
    participant = DDSTheParticipantFactory->create_participant(
    domainId, participant_qos, NULL /* listener */,
    DDS_STATUS_MASK_NONE);
    if (participant == NULL) {
        /* Error */
    }
    ...
}
```

**Modern C++ Example:**

```

#include "rti/rti.hpp" // include all the modern C++ API
#include "monitor/monitor_common.h" // for RTIDefaultMonitor_create
//...
using rti::core::policy::Property;

// Get property policy from default DomainParticipantQos
auto participant_qos =
    dds::core::QosProvider::Default().participant_qos();
auto property_policy = participant_qos.policy<Property>();

// This property turns monitoring on
property_policy.set(Property::Entry("rti.monitor.library",
    "rtimonitoring"));

// This property specifies the entry point (function
// pointer) for the monitoring library.
std::ostringstream monitor_function_to_str;
monitor_function_to_str <<
    reinterpret_cast<void*>(RTIDefaultMonitor_create);
property_policy.set(Property::Entry(
    "rti.monitor.create_function_ptr",
    monitor_function_to_str.str()));

participant_qos << property_policy;

// Create a DomainParticipant with Qos
dds::domain::DomainParticipant participant(0, participant_qos);

...

```

**C Example:**

```

#include "ndds/ndds_c.h"
#include "monitor/monitor_common.h"
...
extern "C" int publisher_main(int domainId, int sample_count)
{
    DDS_DomainParticipantFactory *factory = NULL;
    struct DDS_DomainParticipantQos participantQos =
        DDS_DomainParticipantQos_INITIALIZER;

    DDS_DomainParticipant *participant = NULL;
    factory = DDS_DomainParticipantFactory_get_instance();
    if (factory == NULL) {
        /* error */
    }
    if (DDS_DomainParticipantFactory_get_default_participant_qos(
        factory, &participantQos) != DDS_RETCODE_OK) {
        /* error */
    }
}

```

```

/* This property indicates that the DomainParticipant has
   monitoring turned on. The property name MUST be
   "rti.monitor.library". The value can be anything.*/
if (DDS_PropertyQosPolicyHelper_add_property(
    &participantQos.property,
    "rti.monitor.library", "rtimonitoring",
    DDS_BOOLEAN_FALSE) != DDS_RETCODE_OK) {
    /* error */
}
/* The property name "rti.monitor.create_function_ptr"
   indicates the entry point for the monitoring library.
   The value MUST be the value of the function pointer
   of RTIDefaultMonitor_create */

if (DDS_PropertyQosPolicyHelper_add_pointer_property(
    &participantQos.property,
    "rti.monitor.create_function_ptr", RTIDefaultMonitor_create)
    != DDS_RETCODE_OK) {
    /* error */
}
/* create DomainParticipant with participantQos */
participant=
    DDS_DomainParticipantFactory_create_participant(
        factory, domainId, &participantQos,
        NULL /* listener */,
        DDS_STATUS_MASK_NONE);
if (participant == NULL) {
    /* error */
}
DDS_DomainParticipantQos_finalize(&participantQos);
...

```

**Note:**

- In the above code, you may notice that **valueBuffer** is initialized to 17 characters. This is because a pointer (`RTIDefaultMonitor_create`) is at most 8 bytes (on a 64-bit system) and it takes two characters to represent a byte in hex. So the total size must be:

```
(2 * 8 characters) + 1 null-termination character = 17 characters
```

2. Link the *Monitoring Library* for your platform into your application at compile time (the Monitoring libraries are listed in the [RTI Connex Core Libraries Platform Notes](#)).

The kind of monitoring library that you link into your application at compile time must be consistent with the kind of *Connex* libraries that you are linking into your application (static/dynamic, release/debug version of the libraries).

**On Windows systems:** If you are linking a static monitoring library, you will also need to link in **Psapi.lib** at compile time.

### 59.1.2.0.2 Method 2-B: Change the Participant QoS by Specifying the Monitoring Library Create Function Pointer in an Environment Variable

This is similar to Method 2-A, but if you specify the function pointer value for **rti.monitor.create\_function\_ptr** in an environment variable that is set programmatically, you can specify your QoS either in an XML file or in source code. If you specify the QoS in an XML file, you can enable/disable monitoring without recompiling. If you change the QoS in your source code, you may need to recompile every time you enable/disable monitoring.

1. In XML, enable monitoring by setting the **rti.monitor.create\_function\_ptr** property to an environment variable. In our example, the variable is named **RTIMONITORFUNCPTR**.

```
<domain_participant_qos>
  <property>
    <value>
      <element>
        <name>rti.monitor.library</name>
        <value>rtimonitoring</value>
      </element>
      <element>
        <name>rti.monitor.create_function_ptr</name>
        <value>$(RTIMONITORFUNCPTR)</value>
      </element>
    </value>
  </property>
</domain_participant_qos>
```

2. In the DDS application that links in the monitoring library, get the function pointer of **RTIDefaultMonitor\_create** and write it to the same environment variable you named in Step 1 and create a *DomainParticipant* by using the XML profile specified in Step 1. (Setting of the environment variable must appear in the application *before* it creates the *DomainParticipant* using the profile from Step 1.)

Here is an example in C:

```
#include <stdio.h>
#include <stdlib.h>
#include "monitor/monitor_common.h"
...
char putenvBuffer[34];
int putenvReturn;
putenvBuffer[0] = '\0';
sprintf(putenvBuffer, "RTIMONITORFUNCPTR=%p",
        RTIDefaultMonitor_create);
putenvReturn = putenv(putenvBuffer);
if (putenvReturn) {
    printf(
        "Error: couldn't set env variable for RTIMONITORFUNCPTR. "
        "error code: %d\n", putenvReturn );
}
...
/* create DomainParticipant using XML profile from Step 1 */
...
```

**Note:** In the above code, you may notice that `putenvBuffer` is initialized to 34 characters. This is because a pointer (`RTIDefaultMonitor_create`) is at most 8 bytes (on a 64-bit system) and it takes 2 characters to represent a byte in hex. So the total size must be: `strlen(RTIMONITORFUNCPTR) + (2 * 8 characters) + 1 null-termination character = 17 + 16 + 1 = 34 characters`

3. Link the *Monitoring Library* for your platform into your application at compile time (the Monitoring libraries are listed in the [RTI Connext Core Libraries Platform Notes](#)).

The kind of monitoring library that you link into your application at compile time must be consistent with the kind of *Connext* libraries that you are linking into your application (static/dynamic, release/debug version of the libraries).

**On Windows systems:** If you are linking a static monitoring library, you will also need to link in `Psapi.lib` at compile time.

## 59.2 How Does Monitoring Work?

*Monitoring Library* works by creating DDS Topics that publish information about the other DDS entities contained in the same operating system process. The Topics can be created inside of the first *DomainParticipant* that enables the library (the default). Or they may be created in a separate *DomainParticipant* if the `rti.monitor.config.new_participant_domain_id` property is used. Use cases for this latter configuration include controlling the domain ID on which this information is exchanged (for example to ensure that this data does not interfere with production topics) as well as the ability to specify the QoS that is used for the *DomainParticipant* (through the `rti.monitor.config.qos_library` and `rti.monitor.config.qos_profile` properties). It may be desirable to specify the QoS for *Monitoring Library's DomainParticipant* if the information will be consumed on a different transport or simply to enable the feature but keep it as isolated from the production system as possible.

## 59.3 What Monitoring Topics are Published?

Two categories of predefined monitoring topics are sent out:

- *Descriptions* are published when an entity is created or deleted, or there are QoS changes (see [Table 59.1 Descriptions \(QoS and Other Static System Information\)](#)).
- *Entity Statistics* are published periodically (see [Table 59.2 Entity Statistics \(Statuses, Aggregated Statuses, CPU and Memory Usage\)](#)).

**Table 59.1 Descriptions (QoS and Other Static System Information)**

Topic Name	Topic Contents
rti/dds/monitoring/domainParticipantDescription	<i>DomainParticipant</i> QoS and other static information
rti/dds/monitoring/topicDescription	<i>Topic</i> QoS and other static information
rti/dds/monitoring/publisherDescription	<i>Publisher</i> QoS and other static information
rti/dds/monitoring/subscriberDescription	<i>Subscriber</i> QoS and other static information
rti/dds/monitoring/dataReaderDescription	<i>DataReader</i> QoS and other static information
rti/dds/monitoring/dataWriterDescription	<i>DataWriter</i> QoS and other static information

**Table 59.2 Entity Statistics (Statuses, Aggregated Statuses, CPU and Memory Usage)**

Topic Name	Topic Contents
rti/dds/monitoring/domainParticipantEntityStatistics	Number of entities discovered in the system, CPU and memory usage of the process
rti/dds/monitoring/dataReaderEntityStatistics	<i>DataReader</i> statuses
rti/dds/monitoring/dataWriterEntityStatistics	<i>DataWriter</i> statuses
rti/dds/monitoring/topicEntityStatistics	<i>Topic</i> statuses
rti/dds/monitoring/ dataReaderEntityMatchedPublicationStatistics	<i>DataReader</i> statuses calculated on a per discovered matching writer basis
rti/dds/monitoring/ dataWriterEntityMatchedSubscriptionStatistics	<i>DataWriter</i> statuses calculated on a per discovered matching reader basis
rti/dds/monitoring/ dataWriterEntityMatchedSubscriptionWithLocatorStatistics	<i>DataWriter</i> statuses calculated on a per sending destination basis

All monitoring data are sent out using specially created *DataWriters* with the above topics.

You can configure some aspects of *Monitoring Library*'s behavior, such as which monitoring topics to turn on, which user topics to monitor, how often to publish the statistics topics, and whether to publish monitoring data using (a) the participant created in the user's application that has monitoring turned on or (b) a separate participant created just for publishing monitoring data. See [Configuring Monitoring Library \(59.5 on the next page\)](#).

## 59.4 Enabling Support for Large Type-Code (Optional)

Some monitoring topics have large type-code (larger than the default maximum type code serialized size setting). If you use *Monitor* to display all the monitoring data, it already has all the monitoring types built-in and therefore it uses the default maximum type-code serialized size in the *Connex*

application and there is no problem. However, if you are using any other tools to display monitoring data (such as *rtiddspy* or writing your own application to subscribe to monitoring data), or if your user data-type has large type-code, you may need to increase the maximum type-object serialized size setting in the *DomainParticipantResourceLimitsQosPolicy*.

## 59.5 Configuring Monitoring Library

You can control some aspects of *Monitoring Library*'s behavior by setting the *PropertyQosPolicy* of the *DomainParticipant*, either via an XML QoS profile or in your application's code prior to creating the *DomainParticipant*.

Two example QoS profiles are provided in

`<path to examples>/connext_dds/qos/MONITORING_LIBRARY_QOS_PROFILES.xml` (see [Paths Mentioned in Documentation on page 1](#)):

- *CustomerExampleMonitoringLibrary::CustomerExampleMonitoringProfile*

This is an example of how to enable *Monitoring Library* for your applications. It can be used as a guide to enabling *Monitoring Library* quickly in your applications.

- *RTIMonitoringQosLibrary::RTIMonitoringQosProfile*

This profile documents the QoS used by *Monitoring Library*. It can also be used as a starting point if you want to tune QoS for *Monitoring Library* (normally not necessary). Use cases for this include customizing *DomainParticipant* QoS (often the transports) to accommodate preferences or environment. This same profile can also be used to subscribe to the *Monitoring Library* Topics. This is useful in situations where the *Monitoring Library* information can be used directly by system components or it is not possible to use the *RTI Monitor* tool.

`<NDDSHOME>/resource/xml/RTI_MONITOR_QOS_PROFILES.xml` is used by the *RTI Monitor* tool. See *Changing Transport Settings in the Configuration File*, in the [RTI Monitor User's Manual](#) for more information.

See the [qos\\_library on page 1138](#) and [qos\\_profile on page 1138](#) properties in [Table 59.3 Configuration Properties for Monitoring Library](#) for further information on when to use the example profiles in `MONITORING_LIBRARY_QOS_PROFILES.xml`.

[Table 59.3 Configuration Properties for Monitoring Library](#) lists the configuration properties that you can set for *Monitoring Library*. These properties are immutable; they cannot be changed after the *DomainParticipant* is created.

Table 59.3 Configuration Properties for Monitoring Library

Property Name (all must be prepended with "rti.monitor.config.")	Property Value
get_process_statistics	<p>This boolean value specifies whether or not <i>Monitoring Library</i> should collect CPU and memory usage statistics for the process in the topic <b>rti/dds/monitoring/domainParticipantDescription</b>.</p> <p>This property is only applicable for platforms that support obtaining CPU and memory usage from monitoring data. CPU and memory usage is not available on these platforms: VxWorks, INTEGRITY.</p> <p>CPU usage is reported in terms of time spent since the process has been started. It can be longer than the actual running time of the process on a multi-core machine.</p> <p>Default: true if unspecified</p>
new_participant_domain_id	<p>To create a separate participant that will be used to publish monitoring information in the application, set this to the domain ID that you want to use for the newly created participant.</p> <p>The new participant is created with the default Qos (for example, that defined in USER_QOS_PROFILES.xml), unless the <a href="#">qos_library on the next page</a> and <a href="#">qos_profile on the next page</a> properties are set.</p> <p>Default: Not set (means you want to reuse the participant in your application that has monitoring turned on to publish statistics information for that participant)</p>
publish_period	<p>Period of time to sample and publish all monitoring topics, in units of seconds.</p> <p>Default: 5 if unspecified</p>
publish_thread_priority	<p>Priority of the thread used to sample and publish monitoring data.</p> <p>This value is architecture dependent.</p> <p>Default if unspecified: same as the default used in <i>Connex</i> for the event thread:</p> <p>Windows systems: -2</p> <p>Linux systems: -999999 (meaning use OS-default priority)</p>
publish_thread_stacksize	<p>Stack size used for the thread that samples and publishes monitoring data. This value is architecture dependent.</p> <p>Default if unspecified: same as the default used in <i>Connex</i> for the event thread:</p> <p>Windows systems: -1 (meaning use the default size for the executable).</p> <p>Linux systems: -1 (meaning use OS's default value).</p>
publish_thread_options	<p>Describes the type of thread.</p> <p>Supported values (may be combined with by OR'ing with ' ' as seen in the default below):</p> <ul style="list-style-type: none"> <li>• <b>FLOATING_POINT</b>: Code executed within the thread may perform floating point operations</li> <li>• <b>STDIO</b>: Code executed within the thread may access standard</li> <li>• <b>REALTIME_PRIORITY</b>: The thread will be scheduled on a real-time basis</li> <li>• <b>PRIORITY_ENFORCE</b>: Strictly enforce this thread's priority</li> </ul> <p>Default: <b>FLOATING_POINT STDIO</b> (same as the default used in <i>Connex</i> for the event thread)</p>

Table 59.3 Configuration Properties for Monitoring Library

Property Name (all must be preended with “rti.monitor.config.”)	Property Value
qos_library	<p>Specifies the name of the QoS library that will be used to create the monitoring library <i>DomainParticipant</i>, <i>Publisher</i>, and <i>DataWriters</i>.</p> <p>Default: Not set. If you don't set this property, the entities are created with the following QoS values:</p> <ul style="list-style-type: none"> <li>The <i>DomainParticipant</i> uses the default <i>DomainParticipantQos</i> (for example, that defined in <i>USER_QOS_PROFILES.xml</i>).</li> <li>The <i>Publisher</i> and the <i>DataWriters</i> use a specific QoS configuration that can be found in the library <b>RTIMonitoringQosLibrary</b> in <code>&lt;path to examples&gt;/connext_dds/qos/MONITORING_LIBRARY_QOS_PROFILES.xml</code>. (Note that the <i>Publisher</i> and <i>DataWriters</i> use the values reproduced in this .xml file, but modifying the file has no effect; it is for reference only.)</li> </ul>
qos_profile	<p>Specifies the name of the QoS profile that will be used to create the monitoring library <i>DomainParticipant</i>, <i>Publisher</i>, and <i>DataWriters</i>.</p> <p>Default: Not set. If you don't set this property, the entities are created with the following QoS values:</p> <ul style="list-style-type: none"> <li>The <i>DomainParticipant</i> uses the default <i>DomainParticipantQos</i> (for example, that defined in <i>USER_QOS_PROFILES.xml</i>).</li> <li>The <i>Publisher</i> and the <i>DataWriters</i> use a specific QoS configuration that can be found in the library <b>RTIMonitoringQosLibrary</b> in <code>&lt;path to examples&gt;/connext_dds/qos/MONITORING_LIBRARY_QOS_PROFILES.xml</code>. (Note that the <i>Publisher</i> and <i>DataWriters</i> use the values reproduced in this .xml file, but modifying the file has no effect; it is for reference only.)</li> </ul>
reset_status_change_counts	<p><i>Monitoring Library</i> obtains all statuses of all entities in the <i>Connext</i> application. This boolean value controls whether or not the change counts in those statuses are reset by <i>Monitoring Library</i>.</p> <p>If set to true, the change counts are reset each time <i>Monitoring Library</i> is done accessing them.</p> <p>If set to false, the change counts truly reflect what users will see in their application and are unaffected by the access of the monitoring library.</p> <p>Default: false</p>
skip_monitor_entities	<p>This boolean value controls whether or not the entities created internally by <i>Monitoring Library</i> should be included in the entity counts published by the participant entity statistics topic.</p> <p>If set to true, the internal monitoring entities will not be included in the count. (Thirteen internal writers are created by the monitoring library by default.)</p> <p>Default: true</p>
skip_participant_properties	<p>If set to true, <i>DomainParticipant</i> <i>PropertyQosPolicy</i> name and value pairs will not be sent out through the <i>DomainParticipantDescriptionTopic</i>. This is necessary if you are linking with <i>Monitoring Library</i> and any of these conditions occur:</p> <ul style="list-style-type: none"> <li>The <i>PropertyQosPolicy</i> of a <i>DomainParticipant</i> has more than 64 properties.</li> <li>Any of the properties in <i>PropertyQosPolicy</i> of a <i>DomainParticipant</i> has a name longer than 127 characters or a value longer than 511 characters.</li> </ul> <p>Default: false if unspecified</p>

Table 59.3 Configuration Properties for Monitoring Library

Property Name (all must be preended with “rti.monitor.config.”)	Property Value
skip_reader_properties	<p>If set to true, <i>DataReader</i> PropertyQosPolicy name and value pairs will not be sent out through the dataReader-DescriptionTopic. This is necessary if you are linking with <i>Monitoring Library</i> and any of these conditions occur:</p> <ul style="list-style-type: none"> <li>• The PropertyQosPolicy of a <i>DataReader</i> has more than 64 properties.</li> <li>• Any of the properties in PropertyQosPolicy of a <i>DataReader</i> has a name longer than 127 characters or a value longer than 511 characters.</li> </ul> <p>Default: false if unspecified</p>
skip_writer_properties	<p>If set to true, <i>DataWriter</i> PropertyQosPolicy name and value pairs will not be sent out through the dataWriter-DescriptionTopic. This is necessary if you are linking with <i>Monitoring Library</i> and any of these conditions occur:</p> <ul style="list-style-type: none"> <li>• The PropertyQosPolicy of a <i>DataWriter</i> has more than 64 properties.</li> <li>• Any of the properties in PropertyQosPolicy of a <i>DataWriter</i> has a name longer than 127 characters or a value longer than 511 characters.</li> </ul> <p>Default: false if unspecified</p>
topics	<p>Filter for monitoring topics, with regular expression matching syntax as specified in the <i>Connex</i> documentation (similar to the POSIX fnmatch syntax). For example, if you only want to send description topics and the entity statistics topics, but NOT the matching statistics topics, you can specify <b>**Description,*EntityStatistics*</b>.</p> <p>Default: * if unspecified</p>
usertopics	<p>Filter for user topics, with regular expression matching syntax as specified in the <i>Connex</i> documentation (similar to the POSIX fnmatch syntax). For example, if you only want to send monitoring information for reader/writer/topic entities for topics that start with Foo or Bar, you can specify <b>*Foo*,Bar*</b>.</p> <p>Default: * if unspecified</p>
verbosity	<p>Sets the verbosity on the monitoring library for debugging purposes (does not affect the topic/data that is sent out).</p> <ul style="list-style-type: none"> <li>• -1: Silent</li> <li>• 0: Exceptions only</li> <li>• 1: Warnings</li> <li>• 2 and up: Higher verbosity level</li> </ul> <p>Default: 1 if unspecified</p>
writer_pool_buffer_max_size	<p>Controls the threshold at which dynamic memory allocation is used, expressed as a number of bytes.</p> <p>If the serialized size of the data to be sent is smaller than this size, a pre-allocated writer buffer pool is used to obtain the memory.</p> <p>If the serialized size of the data is larger than this value, the memory is allocated dynamically.</p> <p>This setting can be used to control memory consumption of the monitoring library, at the cost of performance, when the maximum serialized size of the data type is large (which is the case for some description topics' data types) or if you have several participants on the same machine.</p> <p>The default setting is -1, meaning memory is always obtained from the writer buffer pool, whose size is determined by the maximum serialized size.</p>

## 59.6 Troubleshooting Monitoring

### 59.6.1 Enabling Support for Large Type-Code (Optional)

Some monitoring topics have large type-code (larger than the default maximum type code serialized size setting). If you use *Monitor* to display all the monitoring data, it already has all the monitoring types built-in and therefore it uses the default maximum type-code serialized size in the *Connex* application and there is no problem. However, if you are using any other tools to display monitoring data (such as *rtiddsspy* or writing your own application to subscribe to monitoring data), or if your user data-type has large type-code, you may need to increase the maximum type-object serialized size setting in the `DomainParticipantResourceLimitsQosPolicy`.

### 59.6.2 Buffer Allocation Error

*Monitoring Library* obtains the default *DataWriter* QoS from the *Connex* application's *DomainParticipant*. If the application has changed the default QoS Profile, either through application code or in an XML file, *Monitoring Library* will use this new default QoS. In specific scenarios, the new default QoS may cause your *Connex* application to run out of memory and report error messages similar to these:

```
REDAFastBufferPool_growEmptyPoolEA: !allocate buffer of 1210632000 bytes
[D0012|ENABLE]REDAFastBufferPool_newWithNotification:!create fast buffer pool buffers
[D0012|ENABLE]PRESTypePluginDefaultEndpointData_createWriterPool:!create writer buffer pool
[D0012|ENABLE]WriterHistorySessionManager_new:!create newAllocator
[D0012|ENABLE]WriterHistoryMemoryPlugin_createHistory:!create sessionManager
[D0012|ENABLE]PRESWriterHistoryDriver_new:!create _whHnd
[D0012|ENABLE]PRESPsService_enableLocalEndpointWithCursor:!create WriterHistoryDriver
[D0012|ENABLE]PRESPsService_enableAllLocalEndpointsInGroupWithCursor:!enable endpoint
[D0012|ENABLE]PRESPsService_enableGroupWithCursor:!enableAllLocalEndpointsInGroupWithCursor
[D0012|ENABLE]PRESPsService_enableGroup:!enableGroupWithCursor
[D0012|ENABLE]RTIDefaultMonitorPublisher_enableEntitiesAndStartThreadI:!create enable
publisher
[D0012|ENABLE]RTIDefaultMonitorPublisher_onEventNotify:!create enable entities
```

To resolve this problem, either:

- Configure *Monitoring Library* to use a non-default QoS Profile. For details, see [Configuring Monitoring Library \(59.5 on page 1136\)](#).
- Change the default QoS to have a lower value for *DataWriter*'s **initial\_samples**; this field is part of the `ResourceLimitsQosPolicy`.

# Part 10: Alternative Communication Models

This section includes:

- [Topic Queries \(Chapter 60 on page 1142\)](#)
- [Request-Reply \(Chapter 61 on page 1146\)](#)
- [Remote Procedure Calls \(RPC\)—Experimental Feature \(Chapter 62 on page 1170\)](#)

## Chapter 60 Topic Queries

TopicQueries allow a *DataReader* to query the sample cache of its matching *DataWriters*. You can create a TopicQuery with the *DataReader's* **create\_topic\_query()** API. When a *DataReader* creates a TopicQuery, DDS will propagate TopicQueries to other *DomainParticipants* and their *DataWriters*. When a *DataWriter* matching with the *DataReader* that created the TopicQuery receives it, it will send the cached samples that pass the TopicQuery's filter.

Only samples that fall within the **writer\_depth** (in the [47.9 DURABILITY QosPolicy on page 809](#)) for an instance are evaluated against the TopicQuery filter. While the *DataWriter* is waiting for acknowledgements from one or more *DataReaders*, there may temporarily be more than **writer\_depth** samples per instance in the *DataWriter's* queue if the [47.12 HISTORY QosPolicy on page 818](#) **depth** is set to a higher value than **writer\_depth**. Those additional samples past **writer\_depth** are not eligible to be sent in response to the TopicQuery.

To configure how to dispatch a TopicQuery, use the *DataWriter's* [47.24 TOPIC\\_QUERY\\_DISPATCH\\_QosPolicy \(DDS Extension\) on page 854](#). By default, a *DataWriter* ignores TopicQueries unless they are explicitly enabled using this policy.

The delivery of TopicQuery samples occurs in a separate RTPS channel. This allows *DataReaders* to receive TopicQuery samples and live samples in parallel. This is a key difference with respect to the [47.9 DURABILITY QosPolicy on page 809](#).

Late-joining *DataWriters* will also discover existing TopicQueries. To delete a TopicQuery you must use the *DataReader's* **delete\_topic\_query()**.

After deleting a TopicQuery, new *DataWriters* will not discover it and existing *DataWriters* currently publishing cached samples may stop before delivering all of them.

By default, a TopicQuery queries the samples that were in the *DataWriter's* queue at the time the *DataWriter* received the TopicQuery. However, a TopicQuery can be created in “continuous” mode; in this case, a *DataWriter* will continue delivering samples that pass a continuous TopicQuery filter until the *DataReader* application explicitly deletes it.

The samples received in response to a TopicQuery are stored in the associated *DataReader's* cache. Any of the read/take operations can retrieve TopicQuery samples. The field **DDS\_SampleInfo::topic\_query\_guid** associates each sample with its TopicQuery. If the read sample is not in response to a TopicQuery, this field will be **DDS\_GUID\_UNKNOWN**.

You can choose to read or take only TopicQuery samples, only live samples, or both. To support this, ReadConditions and QueryConditions provide the *DataReader's* **create\_querycondition\_w\_params()** and **create\_readcondition\_w\_params()** APIs.

Each TopicQuery is identified by a GUID that can be accessed using the TopicQuery's **get\_guid()** method.

## 60.1 Reading TopicQuery Samples

Data samples that are received by a *DataReader* in response to a TopicQuery can be identified with two pieces of information from the corresponding DDS\_SampleInfo to the sample. First, if the **DDS\_SampleInfo::topic\_query\_guid** is not equal to **DDS\_GUID\_UNKNOWN**, then the sample is in response to the TopicQuery with that GUID. Second, if the sample is in response to a TopicQuery and the DDS\_SampleInfo::flag **DDS\_INTERMEDIATE\_TOPIC\_QUERY\_SAMPLE** flag is set, then this is not the last sample in response to the TopicQuery for a *DataWriter* identified by **DDS\_SampleInfo::original\_publication\_virtual\_guid**. If that flag is not set, then there will be no more samples corresponding to that TopicQuery coming from the *DataWriter*.

## 60.2 Debugging Topic Queries

There are a number of ways in which to gain more insight into what is happening in an application that is creating Topic Queries.

### 60.2.1 The Built-in ServiceRequest DataReader

TopicQueries are communicated to publishing applications through a built-in ServiceRequest channel. The ServiceRequest channel is designed to be generic so that it can be used for many different purposes, one of which is TopicQueries.

When a *DataReader* creates a TopicQuery, a ServiceRequest message is sent containing the TopicQuery information. Just as there are built-in *DataReaders* for ParticipantBuiltinTopicData, SubscriptionBuiltinTopicData, and PublicationBuiltinTopicData, there is a fourth built-in *DataReader* for ServiceRequests. This built-in DataReader can be retrieved using the built-in Subscriber and its **lookup\_datareader()**. The topic name is **DDS\_SERVICE\_REQUEST\_TOPIC\_NAME**. Installing a listener with the DataReaderListener's **on\_data\_available callback()** implemented will allow a publishing application to be notified whenever a TopicQuery has been received from a subscribing application.

The **service\_id** of a ServiceRequest corresponding to a TopicQuery will be **DDS\_TOPIC\_QUERY\_SERVICE\_REQUEST\_ID** and the **instance\_id** will be equal to the GUID of the TopicQuery.

The `request_body` is a sequence of bytes containing more information about the `TopicQuery`. This information can be retrieved using the `DDS_TopicQueryHelper_topic_query_data_from_service_request()` function. The resulting `TopicQueryData` contains the `TopicQuerySelection` that the `TopicQuery` was created with, the GUID of the original `DataReader` that created the `TopicQuery`, and the topic name of that `DataReader`.

When `TopicQueries` are propagated through one or more instances of `Routing Service`, the last `DataReader` that issued the `TopicQuery` will be a `Routing Service DataReader`. The `DDS_TopicQueryData::original_related_reader_guid`, however, will be that of the first `DataReader` to have created the `TopicQuery`.

If you are seeing traffic from the `ServiceRequest` endpoints during system startup but are not using any of the features (such as `TopicQueries`) that rely on the `ServiceRequest` channel, you can disable the channel using the `enabled_builtin_channels` field in the [44.3 DISCOVERY\\_CONFIG QosPolicy \(DDS Extension\) on page 703](#).

## 60.2.2 The `on_service_request_accepted()` `DataWriter` Listener Callback

It is possible that a `ServiceRequest` for a `TopicQuery` is received but is not immediately dispatched to a `DataWriter`. This can happen, for example, if a `DataWriter` was not matching with a `DataReader` at the time that the `TopicQuery` was received by the publishing application. The `DDS_DataWriterListener`'s `on_service_request_accepted()` callback notifies a `DataWriter` when a `ServiceRequest` has been dispatched to that `DataWriter`. The `DDS_ServiceRequestAcceptedStatus` provides information about how many `ServiceRequests` have been accepted by the `DataWriter` since the last time that the status was read. The status also includes the `DDS_ServiceRequestAcceptedStatus::last_request_handle`, which is the `InstanceHandle` of the last `ServiceRequest` that was accepted. This instance handle can be used to read samples per instance from the built-in `ServiceRequest DataReader` and correlate which `ServiceRequests` have been dispatched to which `DataWriters`.

## 60.3 System Resource Considerations

### 60.3.1 Publishing Application

On the publishing side, the resource allocation associated with `TopicQueries` can be controlled using `remote_topic_query_allocation` (in the [44.4 DOMAIN\\_PARTICIPANT\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 714](#) at the `DomainParticipant` level).

At the `DataWriter` level, you can control how many `TopicQueries` can be served in parallel by the `DataWriter` by setting the resource limit `max_active_topic_queries` in the [47.6 DATA\\_WRITER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 800](#).

### 60.3.2 Subscribing Application

On the `DataReader` side, each `TopicQuery` will get its own resources. These resources will not interfere with the resource limits associated with live data samples or other `TopicQueries`. For example, if `max_`

**samples** (see [47.22 RESOURCE\\_LIMITS QosPolicy on page 850](#)) is set to 10 and the *DataReader* creates one *TopicQuery*, then the *DataReader* will be able to store 10 samples for that *TopicQuery* and 10 samples for live data.

The maximum number of active *TopicQueries* that can be associated with a *DataReader* is configured using the resource limit **max\_topic\_queries** (see [48.2 DATA\\_READER\\_RESOURCE\\_LIMITS QosPolicy \(DDS Extension\) on page 876](#)).

# Chapter 61 Request-Reply

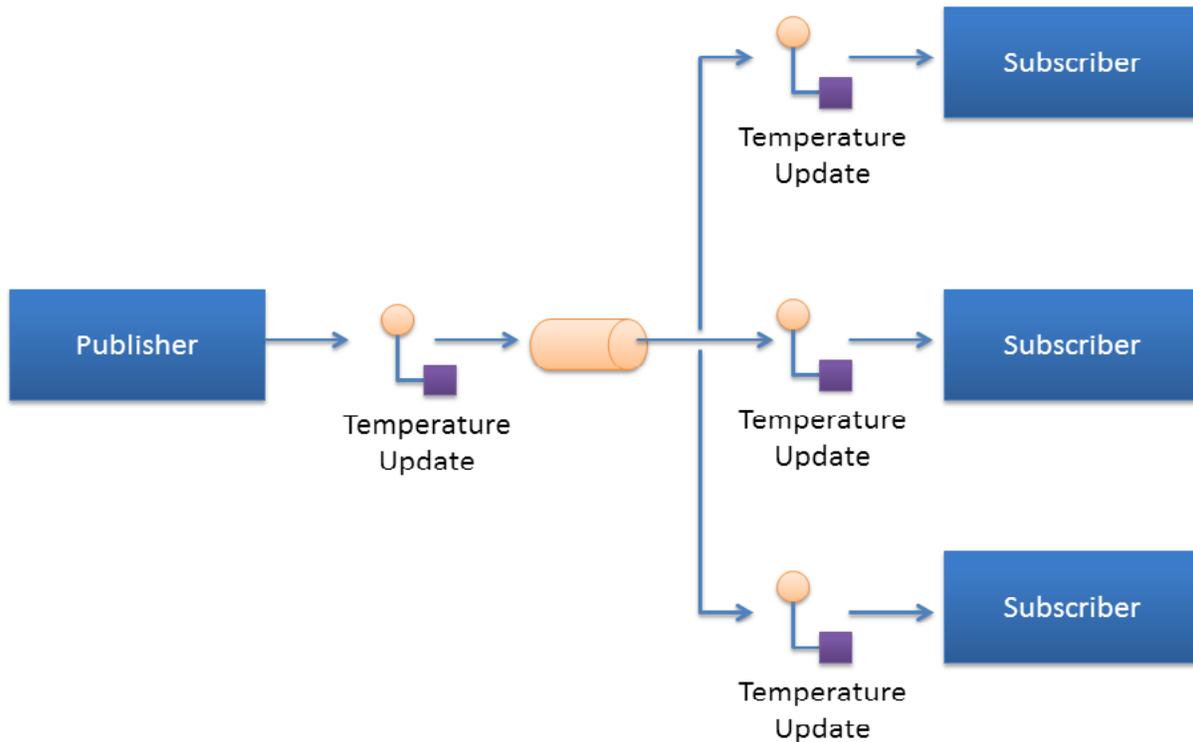

As real-time and embedded applications become more complex, and require integration with enterprise applications, you may need additional communication patterns besides publish-subscribe. Perhaps your application needs certain information only occasionally—such as changes in temperature over the past hour, or even just once, such as application configuration data that is required only at startup. To get information only when needed, *Connex* supports a *request-reply* communication pattern, which is described in the following sections:

- [Introduction to the Request-Reply Communication Pattern \(61.1 below\)](#)
- [Using the Request-Reply Communication Pattern \(61.2 on page 1151\)](#)

## 61.1 Introduction to the Request-Reply Communication Pattern

The fundamental communication pattern provided by *Connex* is known as DDS data-centric *publish-subscribe*. The data-centric publish-subscribe pattern is particularly well-suited in situations where the same data must flow from one producer to many consumers, or when data is streaming continuously from producers to consumers. For example, the values produced by a temperature sensor may be observed by multiple applications, such as control applications, UI applications, supervisory applications, historians, etc.

Figure 61.1: Publish-Subscribe Overview

*Sending temperature updates using the publish-subscribe pattern*

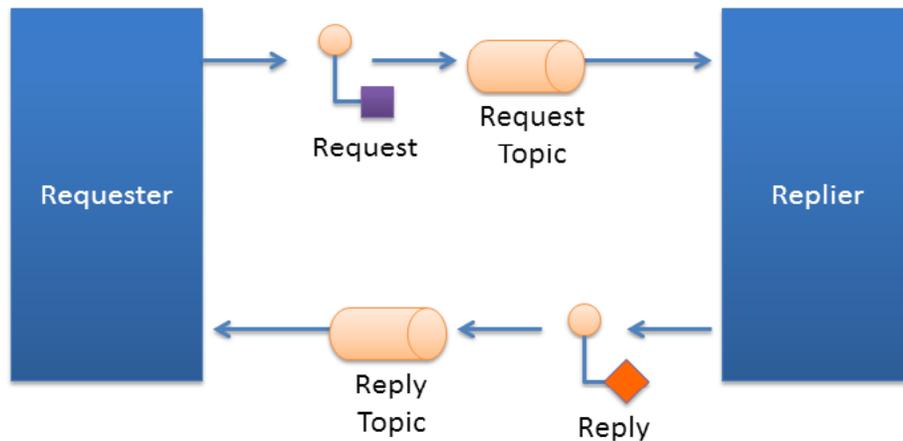

The publish-subscribe pattern supports multicast, which allows efficient distribution from a single source to multiple applications, devices, or subscribers simultaneously. But even with a single subscriber, the publish-subscribe pattern is still advantageous, because the publisher can push new updates to a subscriber as soon as they happen. That way the subscriber always has access to the latest data, with minimum delays, and without incurring the overhead of periodically polling what may be stale data. This efficient, low-latency access to the most current information is important for real-time applications.

### 61.1.1 The Request-Reply Pattern

As applications become more complex, it often becomes necessary to use other communication patterns in addition to publish-subscribe. Sometimes an application needs to get a one-time snapshot of information; for example, to make a query into a database or retrieve configuration parameters that never change. Other times an application needs to ask a remote application to perform an action on its behalf; for example, to invoke a remote procedure call or a service.

To support these scenarios, *Connex* includes support for the request-reply communication pattern.

Figure 61.2: Request-Reply Overview

*Request-Reply communication pattern using a Requester and a Replier*

The request-reply pattern has two roles: The requester (service consumer or client) sends a request message and waits for a reply message. The replier (service provider) receives the request message and responds with a reply message.

Using the request-reply pattern with a *Replier* is straightforward. *Connex* provides two Entities: the *Requester* and the *Replier* manage all the interactions on behalf of the application. The *Requester* and *Replier* automatically discover each other based on an application-specified *service name*. When the application invokes a request, the *Requester* sends a message (on an automatically-created request *Topic*) to the *Replier*, which notifies the receiving application. The application, in turn, uses the *Replier* to receive the request and send the reply message. The reply message is sent by *Connex* back to the original *Requester* (using a different automatically created reply *Topic*).

*Connex* supports both blocking and non-blocking request-reply interactions:

- In a blocking (a.k.a. synchronous) interaction, the requesting application blocks while waiting for the reply. This is typical of applications desiring remote-procedure-call or remote-method-invo-cation interactions.
- In a non-blocking (a.k.a. asynchronous) interaction, the requesting application can proceed with other work and gets notified when a reply is available.

[61.2.2 Repliers on page 1160](#) explains how an application can use the methods provided by the *Requester* and the *Replier* to perform both blocking and non-blocking request-reply interactions.

The implementation of request-reply in *Connex* is highly scalable. A *Replier* can receive requests from thousands of *Requesters* at the same time. *Connex* will efficiently deliver each reply only to the original *Requester*, allowing the number of *Requesters* to grow without significantly impacting each other.

### 61.1.1.1 Request-Reply Correlation

An application might have multiple outstanding requests, all originating from the same *Requester*. This can be as a result of using a non-blocking request-reply interaction, or as a result of having multiple application threads using the same *Requester*. Because of this, *Connex* provides a way for the application to correlate a reply with the request it is associated with. This meta-data is provided as part of a *SampleInfo* structure that accompanies the reply.

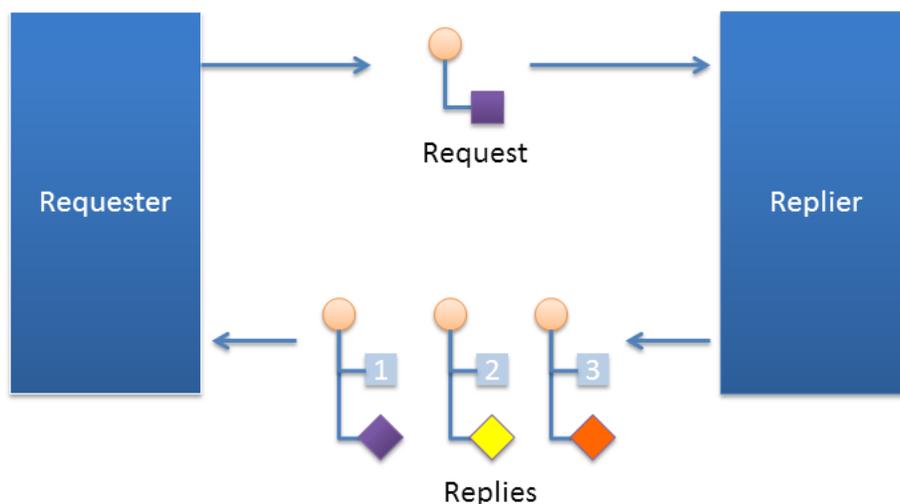

When using a blocking request operation, *Connex* provides an easy-to-use API that automatically does the correlation for you.

### 61.1.2 Single-Request, Multiple-Replies

*Connex* also supports the single-request multiple-reply pattern. This pattern is an extension of the basic request-reply pattern in which multiple reply messages can flow back as a result of a single request.

The single-request multiple-reply pattern is very useful when getting large amounts of data as a reply, such as when querying a system for all data that matches a certain criteria. Another common use-case is invoking a service that goes through multiple stages and provides updates on each: service commencement, progress reports, and final completion.

**Figure 61.3: Single Request, Multiple Replies**

*Request/Reply communication pattern with multiple replies resulting from a single request*

For example, a mobile asset management system may need to locate a particular asset (truck, locomotive, etc.). The system sends out the request. The first reply that comes back will read “locating.” The service has not yet determined the position, but it notifies the requester that the search operation has started. The second reply might provide a status update on the search, perhaps including a rough area of location. The third and final reply will have the exact location of the asset.

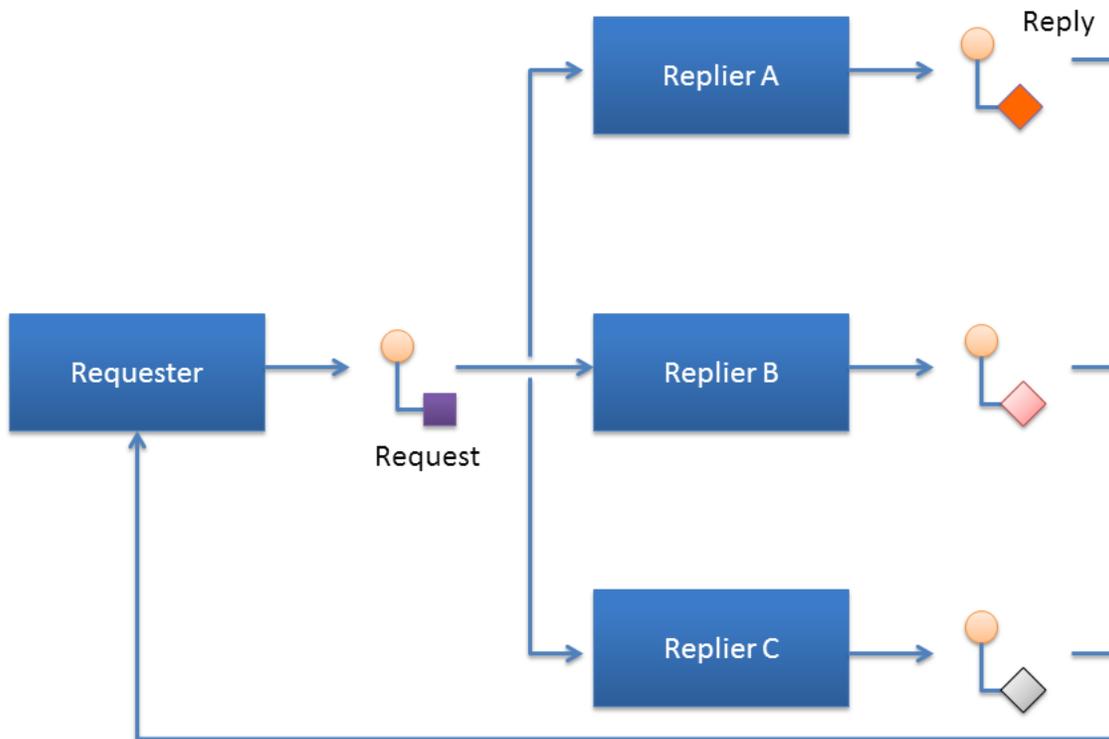

### 61.1.3 Multiple Repliers

*Connex* directly supports applications that obtain results from multiple providers in parallel instead of in sequence, basically implementing functional parallelism.

To illustrate, consider a system managing a fleet of drones, like unmanned aerial vehicles (UAVs). Using the single request-multiple reply pattern, the application can use a *Requester* to send a single 'DroneInfo' request to all the drones to query for their current mission and status. Each drone replies with the information on its own status and the *Requester* aggregates all the responses for the application.

As another example, consider a system that would like to locate the best printer to perform a particular job. The application can use a *Requester* to query all the printers that are on-line for their characteristics and load. The *Requester* receives the replies and accumulates them until an application-specified number of replies is received (or a timeout elapses). The application can then use the *Requester* to access all the replies, examine their contents, and select the best printer for the job.

Figure 61.4: Multiple Repliers

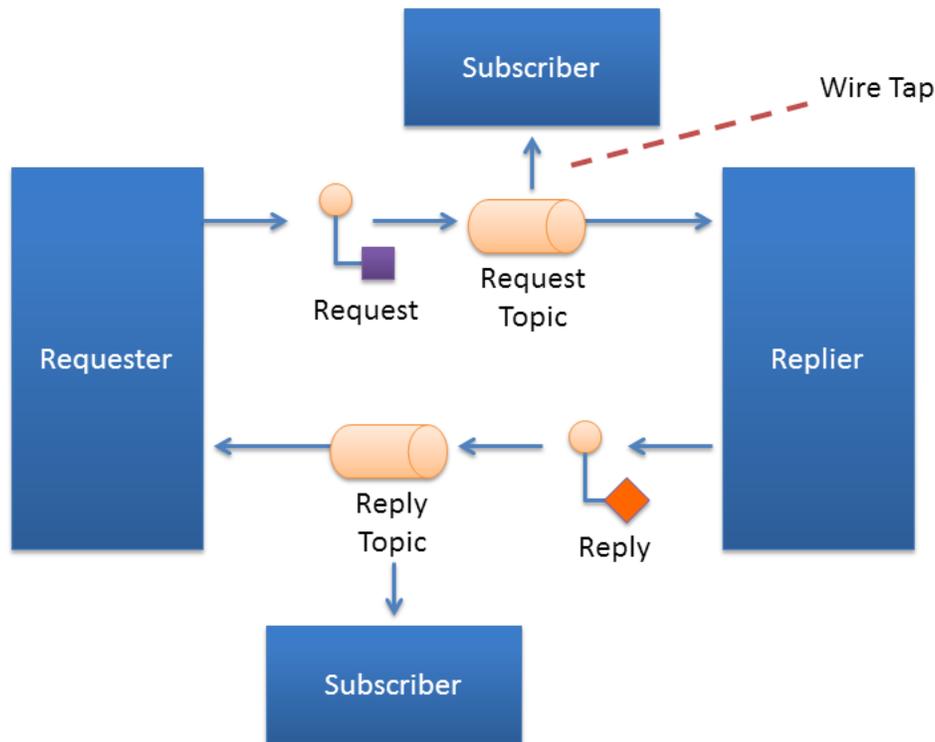

*Request/Reply communication pattern with a single Requester and multiple Repliers*

## 61.1.4 Combining Request-Reply and Publish-Subscribe

Under the hood, *Connex* implements request-reply using the DDS data-centric publish-subscribe pattern. This has a key benefit in that the two patterns can be combined, and mapped without interference.

Figure 61.5: Combining Patterns

Combining Request-Reply and Publish-Subscribe patterns

For example, a pair of applications may be involved in a two-way conversation using request-reply. For debugging purposes or regulatory compliance, you want to inspect those request-reply messages, but without disrupting the conversation.

Since *Connex* implements requests and replies using DDS data-centric publish subscribe, others can simply subscribe to the request and reply messages. You can introduce a subscriber to the reply *Topic*, without interfering with the two-way conversation between the *Requester* and the *Replier*. This pattern is also known as a Wire Tap. For example, you can use *RTI Recording Service* to non-intrusively capture request-reply traffic.

## 61.2 Using the Request-Reply Communication Pattern

There are two basic *Connex* entities used by the Request-Reply communication pattern: *Requester* and *Replier*.

- A *Requester* publishes a request *Topic* and subscribes to a reply *Topic*. See [61.2.1 Requesters below](#).
- A *Replier* subscribes to the request *Topic* and publishes the reply *Topic*. See [61.2.2 Repliers on page 1160](#).

There is an alternate type of replier known as a *SimpleReplier*:

- A *SimpleReplier* is useful for cases where there is a single reply to each request and the reply can be generated quickly, such as looking up some data from memory.
- A *SimpleReplier* is used in combination with a user-provided *SimpleReplierListener*. Requests are passed to a callback in the *SimpleReplierListener*, which returns the reply.
- The *SimpleReplier* is not suitable if the replier needs to generate more than one reply for a single request or if generating the reply can take significant time or needs to occur asynchronously. For more information, see [61.2.3 SimpleRepliers on page 1166](#).

**Additional resources.** In addition to the information in this section, you can find more information and example code here:

- The *Connex* API Reference HTML documentation<sup>1</sup> contains example code that will show you how to use the API: From the **Modules** tab, navigate to **Programming How-To's, Request-Reply Examples**.
- The *Connex* API Reference HTML documentation also contains the full API documentation for the *Requester*, *Replier*, and *SimpleReplier*. Under the **Modules** tab, navigate to **RTI Connex API Reference, RTI Connex Messaging API Reference, Request-Reply Pattern**.

## 61.2.1 Requesters

A *Requester* is an entity with two associated DDS *Entities*: a DDS *DataWriter* bound to a request *Topic* and a DDS *DataReader* bound to a reply *Topic*. A *Requester* sends requests by publishing samples of the request *Topic*, and receives replies for those requests by subscribing to the reply *Topic*.

Valid types for request and reply *Topics* can be:

- For the C API:
  - DDS types generated by RTI Code Generator

---

<sup>1</sup>The API Reference HTML documentation is available for all supported programming languages. Open <NDDSHOME>/README.html.

- For all other APIs:
  - DDS types generated by RTI Code Generator
  - Built-in DDS types, such as, *String*, *KeyedString*, *Octets*, and *KeyedOctets*
  - DDS *DynamicData* Types

To communicate, a *Requester* and *Replier* must use the same request *Topic* name, the same reply *Topic* name, and be associated with the same DDS **domain\_id**.

A *Requester* has an associated *DomainParticipant*, which can be shared with other requesters or *Connex* entities. All the other entities required for request-reply interaction, including the request and reply *Topics*, the *DataWriter* for writing requests, and a *DataReader* for reading replies, are automatically created when the *Requester* is constructed.

*Connex* guarantees that a *Requester* will only receive replies associated with the requests it sends.

The *Requester* uses the underlying *DataReader* not only to receive the replies, but also as a cache that can hold replies to multiple outstanding requests or even multiple replies to a single request. Depending on the *HistoryQoS* configuration of the *DataReader*, the *Requester* may allow replies to replace previous replies based on the reply data having the same value for the Key fields (see [Chapter 8 DDS Samples, Instances, and Keys on page 17](#)). The default configuration of the *Requester* does not allow replacing.

You can configure the QoS for the underlying *DataWriter* and *DataReader* in a QoS profile. By default, the *DataWriter* and *DataReader* are created with default values (DDS\_DATAWRITER\_QOS\_DEFAULT and DDS\_DATAREADER\_QOS\_DEFAULT, respectively) except for the following:

- [47.21 RELIABILITY QoSPolicy on page 845](#): **kind** is set to RELIABLE.
- [47.12 HISTORY QoSPolicy on page 818](#): **kind** is set to KEEP\_ALL.
- Several other protocol-related settings for *Requesters* (see the API Reference HTML documentation: select **Modules, Programming How-To's, Request-Reply Examples**; then scroll down to the section on **Configuring Request-Reply QoS profiles**).

### 61.2.1.1 Creating a Requester

Before you can create a *Requester*, you need a *DomainParticipant* and a service name.

**Note:** The example code snippets in this section use the C++ API. You can find more complete examples in all the supported programming languages (C, C++, Java, C#) in the *Connex* API Reference HTML documentation and in the “example” directory found in your *Connex* installation.

To create a *Requester* with the minimum set of parameters, you can use the basic constructor that receives only an existing DDS *DomainParticipant* and the name of the service:

```
Requester <MyRequestType, MyReplyType> *requester =
    new Requester <MyRequestType, MyReplyType> (
        participant, "ServiceName");
```

To create a *Requester* with specific parameters, you may use a different constructor that receives a *RequesterParams* structure (described in [61.2.1.3 Setting Requester Parameters below](#)):

```
Requester (const RequesterParams &params)
```

The **ServiceName** parameter is used to generate the names of the request and reply *Topics* that the *Requester* and *Replier* will use to communicate. For example, if the service name is “MyService”, the topic names for the *Requester* and *Replier* will be “MyServiceRequest” and “MyServiceReply”, respectively. Therefore, for communication to occur, you must use the same service name when creating the *Requester* and the *Replier* entities.

If you want to use topic names different from the ones that would be derived from the *ServiceName*, you can override the default names by setting the actual request and reply *Topic* names using the **request\_topic\_name()** and **reply\_topic\_name()** accessors to the *RequesterParams* structure prior to creating the *Requester*.

**Example:** To create a *Requester* with default QoS and topic names derived from the service name, you may use the following code:

```
Requester<Foo, Bar> * requester =
    new Requester<Foo, Bar>(
        participant, "MyService");
```

**Example:** To create a *Requester* with a specific QoS profile with library name “MyLibrary” and profile “MyProfile” defined inside **USER\_QOS\_PROFILES.xml** in the current working directory, you may use the following code:

```
Requester<Foo, Bar> * requester = new Requester<Foo, Bar>(
    RequesterParams(participant) .
    service_name("MyService") .qos_profile(
    "MyLibrary", "MyProfile"));
```

Once you have created a *Requester*, you can use it to perform the operations in [Table 61.2 Requester Operations](#).

### 61.2.1.2 Destroying a Requester

To destroy a *Requester* and free its underlying entities you may use the destructor:

```
virtual ~Requester ()
```

### 61.2.1.3 Setting Requester Parameters

To change the *RequesterParams* that can be used when creating a *Requester*, you can use the operations listed in [Table 61.1 Operations to Set Requester Parameters](#).

**Table 61.1 Operations to Set Requester Parameters**

Operation	Description
datareader_qos	Sets the QoS of the reply DataReader.
datawriter_qos	Sets the QoS of the request DataWriter.
publisher	Sets a specific Publisher.
qos_profile	Sets a QoS profile for the DDS entities in this requester.
request_topic_name	Sets the name of the Topic used for the request. If this parameter is set, then you must also set the reply_topic_name parameter and you should not set the service_name parameter.
reply_topic_name	Sets the name of the Topic used for the reply. If this parameter is set, then you must also set the request_topic_name parameter and you should not set the service_name parameter.
reply_type_support	Sets the type support for the reply type.
request_type_support	Sets the type support for the request type.
service_name	Sets the service name. This will automatically set the name of the request Topic and the reply Topic. If this parameter is set you should not set the request_topic_name or the reply_topic_name.
subscriber	Sets a specific Subscriber.

#### 61.2.1.4 Summary of Requester Operations

There are several kinds of operations an application can perform using the *Requester*:

- Sending requests (i.e., publishing request samples on the request *Topic*)
- Waiting for replies to be received.
- Taking the reply data. This gets the reply data from the *Requester* and removes from the *Requester* cache.
- Reading the reply data. This gets the reply data from the *Requester* but leaves it in the *Requester* cache so it remain accessible to future operations on the *Requester*.
- Receiving replies (a convenience operation that is a combination of ‘waiting’ and ‘taking’ the data in a single operation)

These operations are summarized in [Table 61.2 Requester Operations](#)

Table 61.2 Requester Operations

Operation		Description	Reference
Sending Requests	send_request	Sends a request.	<a href="#">61.2.1.5 Sending Requests below</a>
Waiting for Replies	wait_for_replies	Waits for replies to any request or to a specific request.	<a href="#">61.2.1.6.1 Waiting for Replies on the next page</a>
Taking Reply Data	take_reply	Copies a single reply into a Sample container. There are variants that allow getting the next reply available or the next reply to a specific request. This operation removes the reply from the Requester cache. So subsequent calls to take or read replies will not get the same reply again.	<a href="#">61.2.2 Repliers on page 1160</a>
	take_replies	Returns a LoanedSamples container with the collection of replies received by the Requester. There are variants that allow accessing all the replies available or only the replies to a specific request. This operation removes the returned replies from the Requester cache. So subsequent calls to take or read replies will not get the same replies again.	
Reading Reply Data	read_reply	Copies a single reply into a Sample container. There are variants that allow getting the next reply available or the next reply to a specific request. This operation leaves the reply on the Requester cache. So subsequent calls to take or read replies can get the same reply again.	<a href="#">61.2.2 Repliers on page 1160</a>
	read_replies	Returns a LoanedSamples container with the collection of replies received by the Requester. There are variants that allow accessing all the replies available or only the replies to a specific request. This operation leaves the returned replies in the Requester cache. So subsequent calls to take or read replies can get the same replies again.	
Receiving Replies	receive_reply	Convenience function that combines a call to wait_for_replies with a call to take_reply.	<a href="#">61.2.1.6.3 Receiving Replies on page 1160</a>
	receive_replies	Convenience function that combines a call to wait_for_replies with a call to take_replies.	
Getting Underlying Entities	get_request_datawriter	Retrieves the underlying DataWriter that writes requests.	<a href="#">61.2.4 Accessing Underlying DataWriters and DataReaders on page 1168</a>
	get_reply_datareader	Retrieves the underlying DataReader that reads replies.	

### 61.2.1.5 Sending Requests

To send a request, use the `send_request()` operation on the *Requester*. There are three variants of this operation, depending on the parameters that are passed in:

1. `send_request (const TRequest &request)`
2. `send_request (WriteSample<TRequest> &request)`
3. `send_request (WriteSampleRef<TRequest> &request)`

The first variant simply sends a request.

The second variant sends a request and gets back information about the request in a *WriteSample* container. This information can be used to correlate the request with future replies.

The third variant is just like the second, but puts the information in a *WriteSampleRef*, which holds references to the data and parameters. Both *WriteSample* and *WriteSampleRef* provide information about the request that can be used to correlate the request with future replies.

### 61.2.1.6 Processing Incoming Replies with a Requester

The *Requester* provides several operations that can be used to wait for and access replies:

- `wait_for_replies()`, see [61.2.1.6.1 Waiting for Replies below](#)
- `take_reply()`, `take_replies()`, `read_reply()` and `read_replies()`, see [61.2.1.6.2 Getting Replies on the next page](#)
- `receive_reply()` and `receive_replies()`, see [61.2.1.6.3 Receiving Replies on page 1160](#)

The `wait_for_replies` operations are used to wait until the replies arrive.

The `take_reply`, `take_replies`, `read_reply`, and `read_replies()` operations access the replies once they have arrived.

The `receive_reply` and `receive_replies` are convenience functions that combine waiting and accessing the replies and are equivalent to calling the ‘wait’ operation followed by the corresponding `take_reply` or `take_replies` operations.

Each of these operations has several variants, depending on the parameters that are passed in.

#### 61.2.1.6.1 Waiting for Replies

Use the `wait_for_replies()` operation on the *Requester* to wait for the replies to previously sent requests. There are three variants of this operation, depending on the parameters that are passed in. All these variants block the calling thread until either there are replies or a timeout occurs.

```
1. wait_for_replies (const DDS_Duration_t &max_wait)
2. wait_for_replies (int min_count,
                    const DDS_Duration_t &max_wait)
3. wait_for_replies (int min_count,
                    const DDS_Duration_t &max_wait,
                    const SampleIdentity_t &related_request_id)
```

The first variant (only passing in `max_wait`) blocks until a reply is available or until `max_wait` time has elapsed, whichever comes first. The reply can be to any of the requests made by the *Requester*.

The second variant (passing in `min_count` and `max_wait`) blocks until at least `min_count` replies are available or until `max_wait` time has elapsed, whichever comes first. These replies may all be to the same request or to different requests made by the *Requester*.

The third variant (passing in **min\_count**, **max\_wait**, and **related\_request\_id**) blocks until at least **min\_count** replies to the request identified by the **related\_request\_id** are available, or until **max\_wait** time has passed, whichever comes first. Note that unlike the previous variants, the replies must all be to the same single request (identified by the **related\_request\_id**) made by the *Requester*.

Typically after waiting for replies, you will call **take\_reply**, **take\_replies**, **read\_reply**, or **read\_replies** (), see [61.2.2 Repliers on page 1160](#).

If you call **wait\_for\_replies()** several times without ‘taking’ the replies (using the **take\_reply** or **take\_replies** operation), future calls to **wait\_for\_replies()** will return immediately and will not wait for new replies.

### 61.2.1.6.2 Getting Replies

You can use the following operations to access replies: **take\_reply**, **take\_replies**, **read\_reply**, and **read\_replies()**.

As mentioned in [61.2.1.4 Summary of Requester Operations on page 1155](#), the difference between the ‘take’ operations (**take\_reply**, **take\_replies**) and the ‘read’ operations (**read\_reply**, **read\_replies**) is that ‘take’ operations remove the replies from the *Requester* cache. This means that future calls to **take\_reply**, **read\_reply**, **read\_reply**, and **read\_reply** will not get the same reply again.

The **take\_reply** and **read\_reply** operations access a *single* reply, whereas the **take\_replies** and **read\_replies** can access a *collection* of replies.

There are four variants of the **take\_reply** and **read\_reply** operations, depending on the parameters that are passed in:

```

1. take_reply (Sample<TReply> &reply)
   read_reply (Sample<TReply> &reply)

2. take_reply (SampleRef<TReply> reply)
   read_reply (SampleRef<TReply> reply)

3. take_reply (Sample<TReply> &reply,
              const SampleIdentity_t &related_request_id)
   read_reply (Sample<TReply> &reply,
              const SampleIdentity_t &related_request_id)

4. take_reply (SampleRef<TReply> reply,
              const SampleIdentity_t &related_request_id)
   read_reply (SampleRef<TReply> reply,
              const SampleIdentity_t &related_request_id)

```

The first two variants provide access to the next reply in the *Requester* cache. This is the earliest reply to any previous requests sent by the *Requester* that has not been ‘taken’ from the *Requester* cache. The remaining two variants provide access to the earliest non-previously ‘taken’ reply to the request specified by the **related\_request\_id**.

Notice that some of these variants use a *Sample*, while other use a *SampleRef*. A *SampleRef* can be used much like a *Sample*, but it holds *references* to the reply data and *DDS SampleInfo*, so there is no additional copy. In contrast using the *Sample* obtains a copy of both the data and *DDS SampleInfo*.

The **take\_replies** and **read\_replies** operations access a collection of (one or more) replies to previously sent requests. These operations are convenient when you expect multiple replies to a single request, or when issuing multiple requests concurrently without waiting for intervening replies.

The **take\_replies** and **read\_replies** operations return a *LoanedSamples* container that holds the replies. To increase performance, the *LoanedSamples* does not copy the reply data. Instead it ‘loans’ the necessary resources from the *Requester*. The resources loaned by the *LoanedSamples* container must be eventually returned, either explicitly calling the **return\_loan()** operation on the *LoanedSamples* or through the destructor of the *LoanedSamples*.

There are three variants of the **take\_replies** and **read\_replies** operations, depending on the parameters that are passed in:

```

1. take_replies (int max_count=DDS_LENGTH_UNLIMITED)
   read_replies (int max_count=DDS_LENGTH_UNLIMITED)

2. take_replies (int max_count,
                const SampleIdentity_t &related_request_id)
   read_replies (int max_count,
                const SampleIdentity_t &related_request_id)

3. take_replies (const SampleIdentity_t &related_request_id)
   read_replies (const SampleIdentity_t &related_request_id)

```

The first variant (only passing in **max\_count**) returns a container holding up to **max\_count** replies.

The second variant (passing in **max\_count** and **related\_request\_id**) returns a *LoanedSamples* container holding up to **max\_count** replies that correspond to the request identified by the **related\_request\_id**.

The third variant (only passing in **related\_request\_id**) returns a *LoanedSamples* container holding an unbounded number of replies that correspond to the request identified by the **related\_request\_id**. This is equivalent to the second variant with **max\_count** = **DDS\_LENGTH\_UNLIMITED**.

The resources for the *LoanedSamples* container must be eventually be returned, either by calling the **return\_loan()** operation on the *LoanedSamples* or through the *LoanedSamples* destructor.

For multi-reply scenarios, in which a *Requester* receives multiple replies from a *Replier* for a given request, the *Requester* can check if a reply is the last reply in a sequence of replies. To do so, see if the bit **INTERMEDIATE\_REPLY\_SEQUENCE\_SAMPLE** is set in *DDS\_SampleInfo*’s flag field (see [Table 41.2 DDS\\_SampleInfo Structure](#)) after receiving each reply. This bit indicates it is NOT the last reply.

### 61.2.1.6.3 Receiving Replies

The `receive_reply()` operation is a shortcut that combines calls to `wait_for_replies()` and to `take_reply()`. Similarly the `receive_replies()` operation combines `wait_for_replies()` and `take_replies()`.

There is only one variant of the `receive_reply()` operation:

```
1. receive_reply (Sample<TReply> &reply, const DDS_Duration_t &timeout)
```

This operation blocks until either a reply is received or a timeout occurs. The contents of the reply are copied into the provided sample (`reply`).

There are two variants of the `receive_replies()` operation, depending on the parameters that are passed in:

```
1. receive_replies (const DDS_Duration_t &max_wait)
2. receive_replies (int min_count, int max_count,
                   const DDS_Duration_t &max_wait)
```

These two variants block until *multiple* replies are available or a timeout occurs.

The first variant (only passing in `max_wait`) blocks until at least one reply is available or until `max_wait` time has passed, whichever comes first. The operation returns a *LoanedSamples* container holding the replies. Note that there could be more than one reply. This can occur if, for example, there were already replies available in the *Requester* from previous requests that were not processed. This operation does not limit the number of replies that can be returned on the *LoanedSamples* container.

The second variant (passing in `min_count`, `max_count`, and `max_wait`) will block until `min_count` replies are available or until `max_wait` time has passed, whichever comes first. Up to `max_count` replies will be stored into the *LoanedSamples* container which is returned to the caller.

The resources held in the *LoanedSamples* container must eventually be returned, either with an explicit call to `return_loan()` on the *LoanedSamples* or through the *LoanedSamples* destructor.

## 61.2.2 Repliers

A *Replier* is an entity with two associated DDS *Entities*: a DDS *DataReader* bound to a request *Topic* and a DDS *DataWriter* bound to a reply *Topic*. The *Replier* receives requests by subscribing to the request *Topic* and sends replies to those requests by publishing on the reply *Topic*.

Valid data types for these topics are the same as specified for the *Requester*, see [61.2.1 Requesters on page 1152](#).

For multi-reply scenarios in which a *Replier* generates more than one reply for a request, the *Replier* should mark all intermediate replies (all but the last reply) with the `INTERMEDIATE_REPLY_SEQUENCE_SAMPLE` bit-flag in the `WriteParams_t` flag field (see [Table 31.15 DDS\\_WriteParams\\_t](#)).

Much like a *Requester*, a *Replier* has an associated DDS *DomainParticipant* which can be shared with other *Connex* entities. All the other entities required for the request-reply interaction, including a

*DataWriter* for writing replies and a *DataReader* for reading requests, are automatically created when the *Replier* is constructed.

You can configure the QoS for the underlying *DataWriter* and *DataReader* in a QoS profile. By default, the *DataWriter* and *DataReader* are created with default QoS values (using `DDS_DATAWRITER_QOS_DEFAULT` and `DDS_DATAREADER_QOS_DEFAULT`, respectively) except for the following:

- [47.21 RELIABILITY QosPolicy on page 845](#): **kind** is set to `RELIABLE`
- [47.12 HISTORY QosPolicy on page 818](#): **kind** is set to `KEEP_ALL`

The *Replier* API supports several ways in which the application can be notified of, and process, requests:

- **Blocking**: The application thread blocks waiting for requests, processes them, and dispatches the reply. In this situation, if the computation necessary to process the request and produce the reply is small, you may consider using the *SimpleReplier*, which offers a simplified API.
- **Polling**: The application thread checks (polls) for requests periodically but does not block to wait for them. To check for data without blocking, call `take_requests()` or `read_requests()`.
- **Asynchronous notification**: The application installs a *ReplierListener* to receive notifications whenever a request is received.

### 61.2.2.1 Creating a Replier

To create a *Replier* with the minimum set of parameters you can use the basic constructor that receives only an existing DDS *DomainParticipant* and the name of the service:

```
Replier (DDSDomainParticipant * participant,
         const std::string & service_name)
```

Example:

```
Replier<Foo, Bar> * replier =
    new Replier<Foo, Bar>(participant, "MyService");
```

To create a *Replier* with specific parameters you may use a different constructor that receives a *ReplierParams* structure:

```
Replier (const ReplierParams<TRequest, TReply> &params)
```

Example:

```
Replier<Foo, Bar> * replier = new Replier<Foo, Bar>(
    ReplierParams(participant).service_name("MyService")
    .qos_profile("MyLibrary", "MyProfile"));
```

The **service\_name** is used to generate the names of the request and reply *Topics* that the *Requester* and *Replier* will use to communicate. For example, if the service name is “MyService”, the topic names for the *Requester* and *Replier* will be “MyServiceRequest” and “MyServiceReply”, respectively. Therefore it is important to use the same **service\_name** when creating the *Requester* and the *Replier*.

If you need to specify different *Topic* names, you can override the default names by setting the actual request and reply *Topic* names using **request\_topic\_name()** and **reply\_topic\_name()** accessors to the *ReplierParams* structure prior to creating the *Replier*.

### 61.2.2.2 Destroying a Replier

To destroy a Replier and free its underlying entities:

```
virtual ~Replier ()
```

### 61.2.2.3 Setting Replier Parameters

To change the *ReplierParams* that are used to create a *Replier*, use the operations listed in [Table 61.3 Operations to Set Replier Parameters](#).

**Table 61.3 Operations to Set Replier Parameters**

Operation	Description
datareader_qos	Sets the quality of service of the request <i>DataReader</i> .
datawriter_qos	Sets the quality of service of the reply <i>DataWriter</i> .
publisher	Sets a specific Publisher.
qos_profile	Sets a QoS profile for the entities in this replier.
replier_listener	Sets a listener that is called when requests are available.
reply_topic_name	Sets a specific reply topic name.
reply_type_support	Sets the type support for the reply type.
request_topic_name	Sets a specific request topic name.
request_type_support	Sets the type support for the request type.
service_name	Sets the service name the Replier offers and Requesters use to match.
subscriber	Sets a specific Subscriber.

### 61.2.2.4 Summary of Replier Operations

There are four kinds of operations an application can perform using the *Replier*:

- Waiting for requests to be received
- Reading/taking the request data and associated information
- Receiving requests (a convenience operation that combines waiting and getting the data into a single operation)
- Sending a reply for received request (i.e., publishing a reply sample on the reply *Topic* with special meta-data so that the original *Requester* can identify it).

The *Replier* operations are summarized in [Table 61.4 Replier Operations](#).

**Table 61.4 Replier Operations**

Operation		Description	Reference
Waiting for Requests	wait_for_requests	Waits for requests.	<a href="#">61.2.2.5.1 Waiting for Requests on the next page</a>
Taking Requests	take_request	Copies the contents of a single request into a <i>Sample</i> and removes it from the <i>Replier</i> cache.	<a href="#">61.2.2.5.2 Reading and Taking Requests on the next page</a>
	take_requests	Returns a <i>LoanedSamples</i> to access multiple requests and removes the requests from the <i>Replier</i> cache.	
Reading Requests	read_request	Copies the contents of a single request into a <i>Sample</i> , leaving it in the <i>Replier</i> cache	<a href="#">61.2.2.5.2 Reading and Taking Requests on the next page</a>
	read_requests	Returns a <i>LoanedSamples</i> to access multiple requests, leaving them in the <i>Replier</i> cache.	
Receiving Requests	receive_request	Waits for a single request and copies its contents into a <i>Sample</i> container.	<a href="#">61.2.2.5.3 Receiving Requests on page 1165</a>
	receive_requests	Waits for multiple requests and provides a <i>LoanedSamples</i> container to access them.	
Sending Replies	send_reply	Sends a reply for a previous request.	<a href="#">61.2.2.6 Sending Replies on page 1166</a>
Getting Underlying Entities	get_request_datareader	Retrieves the underlying <i>DataReader</i> .	<a href="#">61.2.4 Accessing Underlying DataWriters and DataReaders on page 1168</a>
	get_reply_datawriter	Retrieves the underlying <i>DataWriter</i> .	

### 61.2.2.5 Processing Incoming Requests with a Replier

The *Replier* provides several operations that can be used to wait for and access the requests:

- **wait\_for\_requests()**, see [61.2.2.5.1 Waiting for Requests on the next page](#)
- **take\_request()**, **take\_requests()**, **read\_request()**, and **read\_requests()**, see [61.2.2.5.2 Reading and Taking Requests on the next page](#)
- **receive\_request()** and **receive\_requests()**, see [61.2.2.5.3 Receiving Requests on page 1165](#)

The `wait_for_requests()` operations are used to wait until requests arrive.

The `take_request()`, `take_requests()`, `read_request()`, and `read_requests()` operations access the requests, once they have arrived.

The `receive_request()` and `receive_requests()` operations are convenience functions that combine waiting for and accessing requests and are equivalent to calling the ‘wait’ operation followed by the corresponding `take_request()` or `take_requests()` operations.

Each of these operations has several variants, depending on the parameters that are passed in.

#### 61.2.2.5.1 Waiting for Requests

Use the `wait_for_requests()` operation on the *Replier* to wait for requests. There are two variants of this operation, depending on the parameters that are passed in. All these variants block the calling thread until either there are replies or a timeout occurs.:

```
1. wait_for_requests (const DDS_Duration_t &max_wait)
2. wait_for_requests (int min_count, const DDS_Duration_t &max_wait)
```

The first variant (only passing in `max_wait`) blocks until one request is available or until `max_wait` time has passed, whichever comes first.

The second variant blocks until `min_count` number of requests are available or until `max_wait` time has passed.

Typically after waiting for requests, you will call `take_request`, `take_requests`, `read_request`, or `read_requests`, see [61.2.2.6 Sending Replies on page 1166](#).

#### 61.2.2.5.2 Reading and Taking Requests

You can use the following four operations to access requests: `take_request`, `take_requests`, `read_request`, or `read_requests`.

As mentioned in [61.2.2.4 Summary of Replier Operations on page 1162](#), the difference between the ‘take’ operations (`take_request`, `take_requests`) and the ‘read’ operations (`read_request`, `read_requests`) is that ‘take’ operations remove the requests from the *Replier* cache. This means that future calls to `take_request`, `take_requests`, `read_request`, or `read_requests` will not get the same request again.

The `take_request` and `read_request` operations access a *single* reply, whereas the `take_requests` and `read_requests` can access a *collection* of replies.

There are two variants of the `take_request` and `read_request` operations, depending on the parameters that are passed in:

```
1. take_request (connext::Sample<TRequest> & request)
   read_request (connext::Sample<TRequest> & request)
```

```
2. take_request (connext::SampleRef<TRequest> request)
   read_request (connext::SampleRef<TRequest> request)
```

The first variant returns the request using a *Sample* container. The second variant uses a *SampleRef* container instead. A *SampleRef* can be used much like a *Sample*, but it holds *references* to the request data and *DDS SampleInfo*, so there is no additional copy. In contrast, using the *Sample* makes a copy of both the data and *DDS SampleInfo*.

The **take\_requests** and **read\_requests** operations access a collection of (one or more) requests in the *Replier* cache. These operations are convenient when you want to batch-process a set of requests.

The **take\_requests** and **read\_requests** operations return a *LoanedSamples* container that holds the requests. To increase performance, the *LoanedSamples* does not copy the request data. Instead it ‘loans’ the necessary resources from the *Replier*. The resources loaned by the *LoanedSamples* container must be eventually returned, either explicitly by calling the **return\_loan()** operation on the *LoanedSamples* or through the destructor of the *LoanedSamples*.

There is only one variant of these operations:

```
1. take_requests (int max_samples = DDS_LENGTH_UNLIMITED)
   read_requests (int max_samples = DDS_LENGTH_UNLIMITED)
```

The returned container may contain up to **max\_samples** number of requests.

### 61.2.2.5.3 Receiving Requests

The **receive\_request()** operation is a shortcut that combines calls to **wait\_for\_requests()** and **take\_request()**. Similarly, the **receive\_requests()** operation combines **wait\_for\_requests()** and **take\_requests()**.

There are two variants of the **receive\_request()** operation:

```
1. receive_request (connext::Sample<TRequest> & request,
                  const DDS_Duration_t & max_wait)
2. receive_request (connext::SampleRef<TRequest> request,
                  const DDS_Duration_t & max_wait)
```

The **receive\_request** operation blocks until either a request is received or a timeout occurs. The contents of the request are copied into the provided container (**request**). The first variant uses a *Sample* container, whereas the second variant uses a *SampleRef* container. A *SampleRef* can be used much like a *Sample*, but it holds *references* to the request data and *DDS SampleInfo*, so there is no additional copy. In contrast, using the *Sample* obtains a copy of both the data and the *DDS SampleInfo*.

There are two variants of the **receive\_requests()** operation, depending on the parameters that are passed in:

```
1. receive_requests (const DDS_Duration_t & max_wait)
2. receive_requests (int min_request_count,
                  int max_request_count,
                  const DDS_Duration_t & max_wait)
```

The **receive\_requests** operation blocks until one or more requests are available, or a timeout occurs.

The first variant (only passing in **max\_wait**) blocks until one request is available or until **max\_wait** time has passed, whichever comes first. The contents of the request are copied into a *LoanedSamples* container which is returned to the caller. An unlimited number of replies can be copied into the container.

The second variant blocks until **min\_request\_count** number of requests are available or until **max\_wait** time has passed, whichever comes first. Up to **max\_request\_count** number of requests will be copied into a *LoanedSamples* container which is returned to the caller.

The resources for the *LoanedSamples* container must eventually be returned, either with **return\_loan()** or through the *LoanedSamples* destructor.

### 61.2.2.6 Sending Replies

There are three variants for **send\_reply()**, depending on the parameters that are passed in:

```
1. send_reply (const TReply & reply,
              const SampleIdentity_t & related_request_id)
2. send_reply (WriteSample<TReply> & reply,
              const SampleIdentity_t & related_request_id)
3. send_reply (WriteSampleRef<TReply> & reply,
              const SampleIdentity_t & related_request_id)
```

This operation sends a reply for a previous request. The related request ID can be retrieved from an existing request *Sample*.

The first variant is recommended if you do not need to change any of the default write parameters.

The other two variants allow you to set custom parameters for writing a reply. Unlike the *Requester*, where retrieving the sample ID for correlation is common, on the *Replier* side using a *WriteSample* or *WriteSampleRef* is only necessary when you need to overwrite the default write parameters. If that's not the case, use the first variant.

One reason to override the default write parameters is a multi-reply scenario in which a *Replier* generates more than one reply for a request. In this case, all the intermediate replies (all but the last reply) should be marked with the `INTERMEDIATE_REPLY_SEQUENCE_SAMPLE` bit-flag in the **flag** field within **WriteSample::info** or **WriteSampleRef::info**.

A *Requester* can detect if a reply is the last reply in a sequence of replies by seeing if `INTERMEDIATE_REPLY_SEQUENCE_SAMPLE` is NOT set in the **flag** field of **Sample::info** after receiving each reply.

## 61.2.3 SimpleRepliers

The *SimpleReplier* offers a simplified API to receive and process requests. The API is based on a user-provided object that implements the *SimpleReplierListener* interface. Requests are passed to the listener

operation implemented by the user-provided object, which processes the request and returns a reply.

The *SimpleReplier* is recommended if each request generates a single reply and computing the reply can be done quickly with very little CPU resources and without calling any operations that may block the processing thread. For example, looking something up in an internal memory-based data structure would be a good use case for using a *SimpleReplier*.

### 61.2.3.1 Creating a SimpleReplier

To create a *SimpleReplier* with the minimum set of parameters, you can use the basic constructor:

```
SimpleReplier (DDSDomainParticipant *participant,
              const std::string &service_name,
              SimpleReplierListener<TRequest, TReply> &listener)
```

To create a *SimpleReplier* with specific parameters, you may use a different constructor that receives a *SimpleReplierParams* structure:

```
SimpleReplier (const SimpleReplierParams<TRequest, TReply> &params)
```

### 61.2.3.2 Destroying a SimpleReplier

To destroy a *SimpleReplier* and free its resources use the destructor:

```
virtual ~SimpleReplier ()
```

### 61.2.3.3 Setting SimpleReplier Parameters

To change the *SimpleReplierParams* used to create a *SimpleReplier*, use the operations in [Table 61.5 Operations to Set SimpleReplier Parameters](#).

**Table 61.5 Operations to Set SimpleReplier Parameters**

Operation	Description
datareader_qos	Sets the quality of service of the reply DataReader.
datawriter_qos	Sets the quality of service of the reply DataWriter.
publisher	Sets a specific Publisher.
qos_profile	Sets a QoS profile for the entities in this replier.
reply_topic_name	Sets a specific reply topic name.
reply_type_support	Sets the type support for the reply type.
request_topic_name	Sets a specific request topic name.
request_type_support	Sets the type support for the request type.

**Table 61.5 Operations to Set SimpleReplier Parameters**

Operation	Description
service_name	Sets the service name the Replier offers and Requesters use to match.
subscriber	Sets a specific Subscriber.

### 61.2.3.4 Getting Requests and Sending Replies with a SimpleReplierListener

The `on_request_available()` operation on the *SimpleReplierListener* receives a request and returns a reply.

```
on_request_available(TRequest &request)
```

This operation gets called when a request is available. It should immediately return a reply. After calling `on_request_available()`, *Connex* will call the operation `return_loan()` on the *SimpleReplierListener*; this gives the application-defined listener an opportunity to release any resources related to computing the previous reply.

```
return_loan(TReply &reply)
```

## 61.2.4 Accessing Underlying DataWriters and DataReaders

Both *Requester* and *Replier* entities have underlying DDS *DataWriter* and *DataReader* entities. These are created automatically when the *Requester* and *Replier* are constructed.

Accessing the *DataWriter* used by a *Requester* may be useful for a number of advanced use cases, such as:

- Finding matching subscriptions (e.g., *Replier* entities), see [31.16.1 Finding Matching Subscriptions on page 442](#)
- Setting a *DataWriterListener*, see [31.4 Setting Up DataWriterListeners on page 395](#)
- Getting *DataWriter* protocol or cache statuses, see [31.6 Statuses for DataWriters on page 397](#)
- Flushing a data batch after sending a number of request samples, see [31.9 Flushing Batches of DDS Data Samples on page 416](#)
- Modifying the QoS

Accessing the reply *DataReader* may be useful for a number of advanced use cases, such as:

- Finding matching publications (e.g., *Requester* entities), see [40.10 Navigating Relationships Among Entities on page 660](#)
- Getting *DataReader* protocol or cache statuses, see [40.5 Checking DataReader Status and](#)

[StatusConditions](#) on page 624 and [40.7 Statuses for DataReaders](#) on page 626.

- Modifying the QoS

To access these underlying objects:

- **RequestDataWriter \* get\_request\_datawriter()**
- **RequestDataReader \* get\_request\_datareader()**
- **ReplyDataWriter \* get\_reply\_datawriter()**
- **ReplyDataReader \* get\_reply\_datareader()**

# Chapter 62 Remote Procedure Calls (RPC)—Experimental Feature

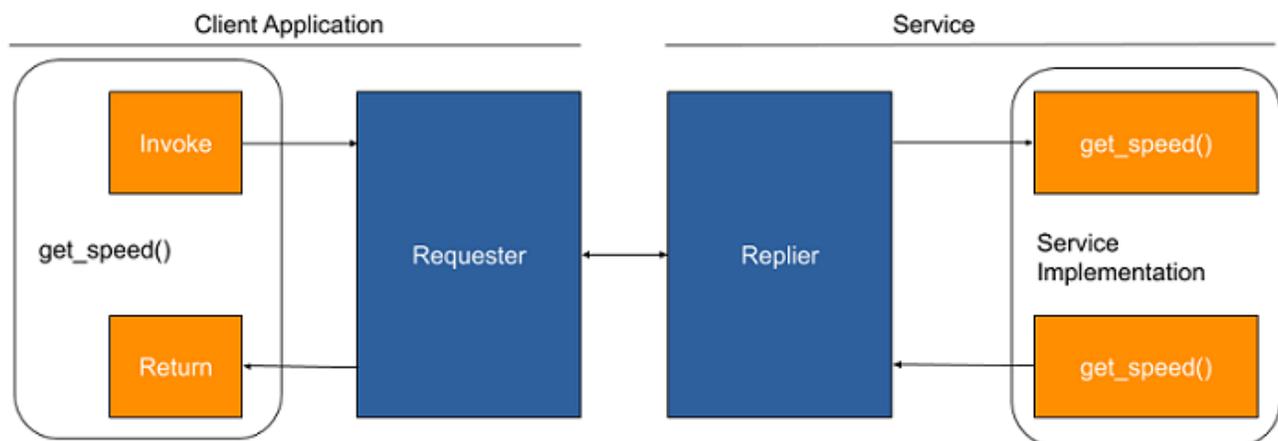

Remote Procedure Calls, or RPC, is an inter-process communication that allows a computer program to cause a subroutine or procedure to execute in another address space.

**Note:** RPC is an experimental feature available only on C++11, for certain platforms. See the [RTI Connext Core Libraries Platform Notes](#) for the supported architectures. See also *Experimental Features* in the [RTI Connext Core Libraries Release Notes](#).

RPC has two participants: a *client* and a *service*. Under the hood, the *client* uses a Requester to send requests and receive replies; the *service* uses a Replier to receive the requests and send the replies.

RPC over DDS uses a function-call style where the *client/Requester* directly calls the *service/Replier* by calling the service's functions, abstracting sending the request and receiving the corresponding reply on the client side.

Figure 62.1: RPC Overview

*Connex* supports both blocking and non-blocking interactions:

- In a blocking (or synchronous) interaction, the client application blocks while waiting for the service's answer.
- In a non-blocking (or asynchronous) interaction, the client application can proceed with other work, ask if the service's answer is already available, or wait for the service's answer.

It is possible for a client to call more than one function at a time, particularly when asynchronous invocations are used.

[62.2 RPC Client on page 1175](#) explains how a client application can use the method provided by the interface to perform both blocking and non-blocking interactions with the service.

**Additional resources.** In addition to the information in this section, you can find more information and example code here:

- The *Connex* API Reference HTML documentation contains example code that will show you how to use the API: From the **Modules** tab, navigate to **Programming How-To's, RPC Tutorial**.
- The *Connex* API Reference HTML documentation also contains the full API documentation for the client-side and server-side APIs. Under the **Modules** tab, navigate to **RTI Connex API Reference, RTI Connex Messaging API Reference, Remote Procedure Call**.

## 62.1 RPC Service

A *service/Replier* receives requests from those *clients/Requesters* that are subscribed to it, and sends replies to those clients. To communicate, a *service* and a *client* must use the same service name, and be associated with the same DDS **domain\_id**.

A *service* has an associated *Replier*. All the entities required by the *Replier*—including the *DomainParticipant*, the request and reply *Topics*, the *DataWriter* for writing replies, and a *DataReader* for reading the requests—are automatically created when the service is created.

You can configure the QoS policies for the underlying *DataWriter* and *DataReader* by setting them either in the *DomainParticipant* that the service is using or in a QoS Profile.

A *service* definition in IDL is represented as an *interface* with the annotation `@DDSService` or `@service`<sup>1</sup>. An interface may define as many operations and attributes as you like. Exceptions are also supported by an interface and can be thrown by operations and attributes.

---

<sup>1</sup>The `@service` annotation receives the type of service as an argument. *Connex* accepts only “DDS” or “\*”. If no parameter is passed to the annotation, “\*” is assumed.

Attributes are defined by using 'attribute' before the type of the attribute. For example: **attribute float speed**. Other elements inside an interface are considered operations. See [62.2.3 Summary of Client Operations on page 1176](#).

```
module robot {
    exception TooFast {};
    enum Command { START_COMMAND, STOP_COMMAND };
    struct Status {
        string msg;
    };

    @DDSService
    interface RobotControl {
        void command(Command com);
        float setSpeed(float speed) raises (TooFast);
        float getSpeed();
        void getStatus(out Status status);
    };
}; //module robot
```

## 62.1.1 Creating a Service

Before you can create a *service/Replier*, you need a *DomainParticipant*, a Server, a ServiceParams, and an instance of the *service interface*.

A Server defines the execution context for one or more *services*. A Server is created with ServerParams, which allow configuring a thread pool that executes the *services*.

```
dds::rpc::ServerParams server_params;
server_params.extensions().thread_pool_size(4);
dds::rpc::Server server(server_params);
```

A *service* requires a *DomainParticipant* and an identifier, which are specified (among other optional configuration parameters) using ServiceParams:

```
dds::domain::DomainParticipant client_participant(domain_id);
dds::rpc::ServiceParams params(participant);
params.service_name("Example RobotControl Service");
```

The **service\_name** function is used to generate the names of the request and reply *Topics* that the internal *Requester (client)* and *Replier (service)* will use to communicate. For example, if the *service* name is “MyService”, the *Topic* names for the *Requester* and *Replier* will be “MyServiceRequest” and “MyServiceReply”, respectively. Therefore, for communication to occur, you must use the same *service* name when creating the *Requester* and the *Replier* entities. If you want to use *Topic* names different from the ones that would be derived from the ServiceName, you can override the default names by setting the actual request and reply *Topic* names using the **request\_topic\_name()** and **reply\_topic\_name()** accessors to the RequesterParams structure before creating the *Requester*.

Next, create an instance of the interface implementation:

```
auto service_impl = std::make_shared<RobotControlExample>();
```

The *service* implementation contains the definition of each operation defined inside the interface in IDL. The *service/Replier* will call these methods upon receiving the request from the *client/Requester*.

Finally, create a *service* for the interface implementation, attached to the server and using the parameters specified before:

```
RobotControlService service(service_impl, server, params);
```

The *service* is ready to receive function calls as soon as it is created.

You can create additional *services* and attach them to the same Server.

Note that just like *DomainParticipant*, 'RobotControlService' and 'server' are reference types and behave like shared pointers. You need to keep one or more references to them to avoid their destruction. You can also use the **run()** operation on the Server to block the current thread, and explicitly call **close()** to unblock it and destroy the Server (see [Table 62.2 Server Operations](#)).

## 62.1.2 Setting the Server Parameters

To change the ServerParameters that can be used when creating a Server (for the *service/Replier*), you can use the operations listed in [Table 62.1 Operations to Set Server Parameters](#).

**Table 62.1 Operations to Set Server Parameters**

Operation	Description
thread_pool_size	Configures the number of threads of a Server thread pool.
async_waitset_property	Allows fine-tuning the internal AsyncWaitSet used to process function calls.

**Note:** These operations are extensions, they must be called via **this->extensions()**.

## 62.1.3 Summary of Server Operations

There are two kinds of operations an application can perform using the Server:

- Running the service
- Closing the service

The Server operations are summarized in [Table 62.2 Server Operations](#).

Table 62.2 Server Operations

Operation		Description	Reference
Run the Server	run	Holds the execution of the current thread.	62.1.4 Running and Closing the Server below
Close the Server	close	Unblocks <b>run()</b> and forces the destruction of this entity. Note that calling <b>close()</b> is not necessary since Server is a reference type and is destroyed automatically when no longer referenced.	

## 62.1.4 Running and Closing the Server

The Server is ready to run as soon as it is created and one or more *services/Repliers* are attached to it. It doesn't require any specific call to start running. However, *Connex* provides two optional **run()** operations that simply hold the execution of the current thread:

- **run (const dds::core::Duration &maxWait)**
- **run ()**

The first operation holds the execution of the current thread for the specified amount of time. The second operation holds the execution of the current thread for an unlimited period of time.

To close the Server, the Server provides a **close()** operation, which unblocks **run()** and then releases all resources.

## 62.1.5 Setting the Service Parameters

To change the ServiceParams that can be used when creating a *service/Replier*, you can use the operations listed in [Table 62.3 Operations to Set Service Parameters](#).

Table 62.3 Operations to Set Service Parameters

Operation	Description
service_name	The service name the <i>Replier</i> offers and <i>Requesters</i> use to match.
request_topic_name	Sets a specific request <i>Topic</i> name.
reply_topic_name	Sets a specific reply <i>Topic</i> name.
datawriter_qos	Sets the Quality of Service of the reply <i>DataWriter</i> .
datareader_qos	Sets the Quality of Service of the reply <i>DataReader</i> .
publisher	Sets a specific <i>Publisher</i> .
subscriber	Sets a specific <i>Subscriber</i> .

Operation	Description
request_type	The request type, when DynamicData is used.
reply_type	The reply type, when DynamicData is used.

## 62.2 RPC Client

A *client* allows making remote function calls to the *services* that it is subscribed to, and receives the results to those calls from those *services*. To communicate, a *client* and a *service* must use the same *service* name, and be associated with the same DDS **domain\_id**.

A *client* has an associated *Requester*. All the entities required by the *Requester*—including the *DomainParticipant*, the request and reply *Topics*, the *DataWriter* for writing the requests, and a *DataReader* for reading replies—are automatically created when the *client* is created.

You can configure the QoS for the underlying *DataWriter* and *DataReader* by setting them either in the *DomainParticipant* that the client is using or in a QoS Profile.

A client is also defined as an interface in IDL with the annotation `@DDSService` or `@service`.

### 62.2.1 Creating a Client

To create a *client/Requester*, you need a *ClientParams*, a *DomainParticipant*, and a *service* name:

```
dds::domain::DomainParticipant client_participant(domain_id);
dds::rpc::ClientParams client_params(client_participant);
client_params.service_name("Example RobotControl Service");
```

The **service\_name** function is used to generate the names of the request and reply *Topics* that the internal *Requester* and *Replier* will use to communicate. For example, if the service name is “MyService”, the *Topic* names for the *Requester* and *Replier* will be “MyServiceRequest” and “MyServiceReply”, respectively. Therefore, for communication to occur, you must use the same service name when creating the *Requester* and the *Replier* entities. If you want to use *Topic* names different from the ones that would be derived from the *ServiceName*, you can override the default names by setting the actual request and reply *Topic* names using the **request\_topic\_name()** and **reply\_topic\_name()** accessors to the *RequesterParams* structure prior to creating the *Requester*.

To create a client, use the constructor that receives the *ClientParams*:

```
RobotControlClient client(client_params);
```

Once you have created a client, you can use it to perform the operations in [Table 62.5 Client Operations](#).

## 62.2.2 Setting the Client Parameters

To change the ClientParams that can be used when creating a *client/Requester*, you can use the operations listed in [Table 62.4 Operations to Set Client Parameters](#).

**Table 62.4 Operations to Set Client Parameters**

Operation	Description
function_call_max_wait	Specifies the maximum wait time for all the remote calls.
service_name	The service name that <i>Replier</i> and <i>Requesters</i> use to match and communicate.
request_topic_name	Sets a specific request <i>Topic</i> name.
reply_topic_name	Sets a specific reply <i>Topic</i> name.
datawriter_qos	Sets the Quality of Service of the request <i>DataWriter</i> .
datareader_qos	Sets the Quality of Service of the request <i>DataReader</i> .
publisher	Sets a specific <i>Publisher</i> .
subscriber	Sets a specific <i>Subscriber</i> .
request_type	The request type, when DynamicData is used.
reply_type	The reply type, when DynamicData is used.

## 62.2.3 Summary of Client Operations

There are several kinds of operations an application can perform using the *client/Requester*:

- Waiting for service to be discovered
- Making remote function calls (synchronous or asynchronous)

The Client operations are summarized in [Table 62.5 Client Operations](#).

The <operation\_name> comes from the IDL file. In the example IDL file in [62.1 RPC Service on page 1171](#), the client will have an operation with the same name as **void command(Command com)**. In the case of an attribute, such as **attribute long test**, the client in C++ will have two operations, named **long get\_operation\_test()**; and **void set\_operation\_test(long test)**; The <attribute\_name> is defined by adding 'attribute' before its type: **attribute <type> <name>**, such as **attribute long test**.

Table 62.5 Client Operations

Operation		Description	Reference
Waiting for Service	wait_for_service	Waits for services.	<a href="#">62.2.4 Waiting for Services below</a>
Sending Request	<operation_name>	Makes a synchronous remote function call.	<a href="#">62.2.5 Making Remote Function Calls below</a>
	<get/set>_attribute_<attribute_name>		
	<operation_name>_async	Makes an asynchronous remote function call.	
	<get/set>_attribute_<attribute_name>_async		
Getting Underlying Entities	request_datawriter	Retrieves the underlying <i>DataWriter</i> that sends the request.	<a href="#">62.3 Accessing Underlying DataWriters and DataReaders on the next page</a>
	reply_datareader	Retrieves the underlying <i>DataReader</i> that receives the replies.	

## 62.2.4 Waiting for Services

The *client/Requester* provides two operations that can be used to wait for services:

- **wait\_for\_service (const dds::core::Duration &maxWait)**
- **wait\_for\_service ()**

The first operation blocks until one service is available or until **maxWait** time has passed, whichever comes first. The second operation blocks until one service is available for an unlimited period of time.

## 62.2.5 Making Remote Function Calls

To send a request, use the operations and attributes defined in the interface:

- **<operation\_name>(<args>)**
- **get\_attribute\_<attribute\_name>(<args>)**
- **set\_attribute\_<attribute\_name>(<args>)**

These functions block the *client* until the *service* sends a reply.

The client also provides asynchronous functions that don't block the client:

- **<operation\_name>\_async(<args>)**
- **get\_attribute\_<attribute\_name>\_async(<args>)**

- `set_attribute_<attribute_name>_async(<args>)`

Asynchronous functions return a `std::future` that will contain the result when it's received:

```
std::future<float> future_speed = client.getSpeed_async();
...
std::cout << "Current speed is " << future_speed.get() << std::endl;
```

The call to `std::future::get()` provides the result if it's already available or blocks until it is.

## 62.3 Accessing Underlying DataWriters and DataReaders

Both *client* and *service* entities have underlying DDS *DataWriter* and *DataReader* entities. These are created automatically when the *client* and *service* are constructed.

Accessing the *DataWriter* used by a *client* may be useful for a number of advanced use cases, such as:

- Finding matching subscriptions (i.e., *service* entities), see [31.16.1 Finding Matching Subscriptions on page 442](#).
- Setting a *DataWriterListener*, see [31.4 Setting Up DataWriterListeners on page 395](#).
- Getting *DataWriter* protocol or cache statuses, see [31.6 Statuses for DataWriters on page 397](#).
- Flushing a data batch after sending a number of request samples, see [31.9 Flushing Batches of DDS Data Samples on page 416](#).
- Modifying the QoS.

Accessing the service *DataReader* may be useful for a number of advanced use cases, such as:

- Finding matching publications (i.e., *client* entities), see [40.10.1 Finding Matching Publications on page 660](#).
- Getting *DataReader* protocol or cache statuses, see [40.5 Checking DataReader Status and StatusConditions on page 624](#) and [40.7 Statuses for DataReaders on page 626](#).
- Modifying the QoS.

To access these underlying objects:

- `dds::pub::DataWriter<RequestType> request_datawriter()`
- `dds::sub::DataReader<ReplyType> reply_datareader()`
- `dds::pub::DataWriter<ReplyType> reply_datawriter()`
- `dds::sub::DataReader<RequestType> request_datareader()`

## 62.4 Generating RPC Code from IDL using RTI Code Generator

To use RPC, add the `@DDSService` or `@service` annotation to an interface in an IDL file. For example:

```
module robot {
    exception TooFast {};
    enum Command { START_COMMAND, STOP_COMMAND };
    struct Status {
        string msg;
    };

    @DDSService
    interface RobotControl {
        void command(Command com);
        float setSpeed(float speed) raises (TooFast);
        float getSpeed();
        void getStatus(out Status status);
    };
}; //module robot
```

This IDL file defines an interface with four methods:

- *command* receives one argument and returns nothing.
- *setSpeed* receives one argument, returns a *float*, and can throw a *TooFast* exception.
- *getSpeed* receives no argument and returns a *float*.
- *getStatus* receives one output argument and returns nothing.

To generate the supporting code and example *client* and *service* applications, run *RTI Code Generator* as follows:

```
rtiddsgen -language C++11 -example <architecture> <IDL file name>.idl
```

This will generate:

- **<IDL file name>.hpp**, **<IDL file name>.cxx**, **<IDL file name>Plugin.hpp**, **<IDL file name>Plugin.cxx**. These files contain the support code for the type defined in the IDL.
- **<IDL file name>\_service.cxx** contains the example service application, and the service implementation.
- **<IDL file name>\_client.cxx** contains the example client application.

For more information and an example, see the RPC Tutorial in the RTI Connexx Modern C++ API Reference HTML documentation.

# Part 11: Connexth Threading Model

This section describes the internal threads that *Connexth* uses for sending and receiving data, maintaining internal state, and calling user code when events occur such as the arrival of new DDS data samples. It may be important for you to understand how these threads may interact with your application.

- [Overview \(Chapter 63 on page 1181\)](#)
- [Database Thread \(Chapter 64 on page 1183\)](#)
- [Event Thread \(Chapter 65 on page 1185\)](#)
- [Receive Threads \(Chapter 66 on page 1187\)](#)
- [Exclusive Areas, RTI Connexth Threads, and User Listeners \(Chapter 67 on page 1190\)](#)
- [Controlling CPU Core Affinity for RTI Threads \(Chapter 68 on page 1191\)](#)
- [Configuring Thread Settings with XML \(Chapter 69 on page 1192\)](#)
- [User-Managed Threads \(Chapter 70 on page 1194\)](#)
- [Unregistering Threads \(Chapter 71 on page 1195\)](#)
- [Identifying Threads Used by Connexth \(Chapter 72 on page 1196\)](#)

# Chapter 63 Overview

A *DomainParticipant* uses three main types of threads:

- **Database Thread** maintains the database of DDS *Entities* stored in the *DomainParticipant*. It is responsible for purging the objects marked for deletion when they are no longer needed. See [Chapter 64 Database Thread on page 1183](#).
- **Event Thread** detects triggered events and acts accordingly, invoking user functions when needed (e.g., when a callback was specified for that specific event). See [Chapter 65 Event Thread on page 1185](#).
- **Receive Threads** get bytes from transport plugins, then deserialize and store the (meta)data in the receive queue of a *DataReader* and invoke the `on_data_available()` callback. Receive threads are also responsible for processing metadata (e.g., discovery traffic, ACKs, NACKs). See [Chapter 66 Receive Threads on page 1187](#).

The actual number of threads depends on the configuration of various QoS policies as well as the implementation of the transports used by the *DomainParticipant* to send and receive data. In addition, other threads might be created for specific purposes:

- **Interface Tracking Thread** retrieves new interface data and compares it with the previous value. The thread detects interface changes and notifies the user/application of the changes. It is used in the IP Mobility feature to detect interface changes. You can disable this thread. See [26.1.1.2 Disabling IP Locator Change Propagation on page 349](#).
- **Transport-Specific Threads** handle the tasks that are specific to a transport (e.g., the TCP Transport plugin creates two threads, one for control and one for events).
- **Asynchronous Publishing Threads** handle the data transmission for Asynchronous Publishers (see [46.1 ASYNCHRONOUS\\_PUBLISHER QosPolicy \(DDS Extension\) on page 740](#)).

- **Asynchronous Batch Flushing Threads** handle batches of data samples, flushing them when needed. These threads are only created when batching is enabled (see [47.2 BATCH QoS Policy \(DDS Extension\) on page 773](#)) and `max_flush_delay` is not `DURATION_INFINITE`.
- **Topic Query Publication Threads** publish historical samples in response to a `TopicQuery`. These threads are only created when topic query dispatch is enabled (see [47.24 TOPIC\\_QUERY\\_DISPATCH\\_QoS Policy \(DDS Extension\) on page 854](#)).
- **User Threads:** in addition, your application may present threads that are not part of *Connex*. If those threads call a DDS API, *Connex* will automatically register them (i.e., allocate some resources to keep statistics and to handle concurrent access to DDS *Entities*). To free up all the allocated resources, you may need to unregister these threads, as explained in [Chapter 71 Unregistering Threads on page 1195](#).

Through various `QoS Policies`, the user application can configure the priorities and other properties of the threads created by *Connex*. In real-time systems, the user often needs to set the priorities of all threads in an application relative to each other for the proper operation of the system.

For information on checking thread names, see [Chapter 72 Identifying Threads Used by Connex on page 1196](#).

# Chapter 64 Database Thread

*Connex* uses internal data structures to store information about locally-created and remotely-discovered *Entities*. In addition, it will store various objects and data used by *Connex* for maintaining proper communications between applications. This “database” is created for each *DomainParticipant*.

As *Entities* and objects are created and deleted during the normal operation of the user application, different entries in the database may be created and deleted as well. Because multiple threads may access objects stored in the database simultaneously, the deletion and removal of an object from the database happens in two phases to support thread safety.

When an entry/object in the database is deleted either through the actions of user code or as a result of a change in system state, it is only marked for deletion. It cannot be actually deleted and removed from the database until *Connex* can be sure that no threads are still accessing the object. Instead, the actual removal of the object is delegated to an internal thread that *Connex* spawns to periodically wake up and purge the database of deleted objects.

This thread is known as the Database thread (also referred to as the database cleanup thread).

- Only one Database thread is created for each *DomainParticipant*.

The [44.1 DATABASE QosPolicy \(DDS Extension\) on page 696](#) of the *DomainParticipant* configures both the resources used by the database as well as the properties of the cleanup thread. Specifically, the user may want to use this QosPolicy to set the priority, stack size and thread options of the cleanup thread. You must set these options before the *DomainParticipant* is created, because once the cleanup thread is started as a part of participant creation, these properties cannot be changed.

The period at which the database-cleanup thread wakes up to purge deleted objects is also set in the DATABASE QosPolicy. Typically, this period is set to a long time (on the order of a minute) since there is no need to waste CPU cycles to wake up a thread only to find nothing to do.

However, when a *DomainParticipant* is destroyed, all of the objects created by the *DomainParticipant* will be destroyed as well. Many of these objects are stored in the database, and thus must be destroyed by the cleanup thread. The *DomainParticipant* cannot be destroyed until the database is empty and is destroyed itself. Thus, there is a different parameter in the DATABASE QosPolicy, `shutdown_cleanup_period`, that is used by the database cleanup thread when the *DomainParticipant* is being destroyed. Typically set to be on the order of a second, this parameter reduces the additional time needed to destroy a *DomainParticipant* simply due to waiting for the cleanup thread to wake up and purge the database.

# Chapter 65 Event Thread

During operation, *Connex* must wake up at different intervals to check the condition of many different time-triggered or periodic events. These events are usually to determine if something happened or did not happen within a specified time. Often the condition must be checked periodically as long as the *Entity* for which the condition applies still exists. Also, the *DomainParticipant* may need to do something periodically to maintain connections with remote *Entities*.

For example, the [47.7 DEADLINE QosPolicy on page 804](#) is used to ensure that *DataWriters* have published data or *DataReaders* have received data within a specified time period. Similarly, the [47.15 LIVELINESS QosPolicy on page 825](#) configures *Connex* both to check periodically to see if a *DataWriter* has sent a liveliness message and to send liveliness messages periodically on the behalf of a *DataWriter*. As a last example, for reliable connections, heartbeats must be sent periodically from the *DataWriter* to the *DataReader* so that the *DataReader* can acknowledge the data that it has received, see [Reliability Models for Sending Data \(Chapter 32 on page 446\)](#).

*Connex* uses an internal thread, known as the Event thread, to do the following:

- Check whether or not deadlines have been missed
- Invoke user-installed *Listener* callbacks to notify the application of missed deadlines
- Send heartbeats to maintain reliable connections

**Note:** Only one Event thread is created per *DomainParticipant*.

The [44.5 EVENT QosPolicy \(DDS Extension\) on page 721](#) of the *DomainParticipant* configures both the properties and resources of the Event thread. Specifically, the user may want to use this QosPolicy to set the priority, stack size and thread options of the Event thread. You must set these options before the *DomainParticipant* is created, because once the Event thread is started as a part of participant creation, these properties cannot be changed.

The EVENT QosPolicy also configures the maximum number of events that can be handled by the Event thread. While the Event thread can only service a single event at a time, it must

maintain a queue to hold events that are pending. The **initial\_count** and **max\_count** parameters of the `QosPolicy` set the initial and maximum size of the queue.

The priority of the Event thread should be carefully set with respect to the priorities of the other threads in a system. While many events can tolerate some amount of latency between the time that the event expires and the time that the Event thread services the event, there may be application-specific events that must be handled as soon as possible.

For example, if an application uses the liveliness of a remote *DataWriter* to infer the correct operation of a remote application, it may be critical for the user code in the *DataReader Listener* callback, **on\_liveliness\_changed()**, to be called by the Event thread as soon as it can be determined that the remote application has died. The operating system uses the priority of the Event thread to schedule this action.

## Chapter 66 Receive Threads

*Connex* uses internal threads, known as Receive threads, to process the data packets received via underlying network transports. These data packets may contain meta-traffic exchanged by *DomainParticipants* for discovery, or user data (and meta-data to support reliable connections) destined for local *DataReaders*.

As a result of processing packets received by a transport, a Receive thread may respond by sending packets on the network. Discovery packets may be sent to other *DomainParticipants* in response to ones received. ACK/NACK packets are sent in response to heartbeats to support a reliable connection.

When a DDS sample arrives, the Receive thread is responsible for deserializing and storing the data in the receive queue of a *DataReader* as well as invoking the **on\_data\_available()** *DataReaderListener* callback (see [40.4 Setting Up DataReaderListeners on page 622](#)).

The number of Receive threads that *Connex* will create for a *DomainParticipant* depends on how you have configured the QoS Policies of *DomainParticipants*, *DataWriters* and *DataReaders* as well as on the implementation of a particular transport. The behavior of the builtin transports is well specified. However, if a custom transport is installed for a *DomainParticipant*, you will have to understand how the custom transport works to predict how many Receive threads will be created.

The following discussion applies on a per-transport basis. A single Receive thread will only service a single transport.

*Connex* will try to create receive resources<sup>1</sup> for every port of every transport on which it is configured to receive messages. The [47.28 TRANSPORT\\_UNICAST QoS Policy \(DDS Extension\) on page 859](#) for *DomainParticipant*, *DataWriters*, and *DataReaders*, the [48.5 TRANSPORT\\_MULTICAST QoS Policy \(DDS Extension\) on page 891](#) for *DataReaders* and the [44.2](#)

---

<sup>1</sup>If UDPv4 was the only transport that *Connex* supports, we would call these receive resources ‘sockets.’

[DISCOVERY QosPolicy \(DDS Extension\) on page 699](#) for *DomainParticipants* all configure the number of ports and the number of transports that *Connex*t will try to use for receiving messages.

Generally, transports will require *Connex*t to create a new receive resource for every unique port number. However, this is both dependent on how the underlying physical transport works and the implementation of the transport plug-in used by *Connex*t. Sometimes *Connex*t only needs to create a single receive resource for any number of ports.

When *Connex*t finds that it is configured to receive data on a port for a transport for which it has not already created a receive resource, it will ask the transport if any of the existing receive resources created for the transport can be shared. If so, then *Connex*t will not have to create a new receive resource. If not, then *Connex*t will.

The `TRANSPORT_UNICAST`, `TRANSPORT_MULTICAST`, and `DISCOVERY` QosPolicies allow you customize ports for receiving user data (on a per-*DataReader* basis) and meta-traffic (*DataWriters* and *DomainParticipants*); ports can be also set differently for unicast and multicast.

How do receive resources relate to Receive threads? *Connex*t will create a Receive thread to service every receive resource that is created. If you use a socket analogy, then for every socket created, *Connex*t will use a separate thread to process the data received on that socket.

So how many threads will *Connex*t create by default—using only the builtin UDPv4 and shared memory transports and without modifying any QosPolicies?

Three Receive threads are created for meta-traffic<sup>1</sup>:

- 2 for unicast (one for UDPv4, one for shared memory)
- 1 for multicast (for UDPv4)<sup>2</sup>

Two Receive threads created for user data:

- 2 for unicast (UDPv4, shared memory)
- 0 for multicast (because user data is not sent via multicast by default)

Therefore, by default, you will have a total of five Receive threads per *DomainParticipant*. By using only a single transport and disabling multicast, a *DomainParticipant* can have as few as 2 Receive threads.

---

<sup>1</sup>Meta-traffic refers to traffic internal to *Connex*t related to dynamic discovery (see [Discovery Overview \(Chapter 22 on page 309\)](#)).

<sup>2</sup>Multicast is not supported by shared memory transports.

Similar to the Database and Event threads, a Receive thread is configured by the [44.6 RECEIVER\\_POOL QosPolicy \(DDS Extension\) on page 723](#). However, note that the thread properties in the RECEIVER\_POOL QosPolicy apply to all Receive threads created for the *DomainParticipant*.

# Chapter 67 Exclusive Areas, RTI Connex

## Threads, and User Listeners

*Connex* Event and Receive threads may invoke user code through the *Listener* callbacks installed on different *Entities* while executing internal *Connex* code. In turn, user code inside the callbacks may invoke *Connex* APIs that reenter the internal code space of *Connex*. For thread safety, *Connex* allocates and uses mutual exclusion semaphores (mutexes).

As discussed in [15.8.8 Exclusive Areas \(EAs\) on page 54](#), when multiple threads and multiple mutexes are mixed together, deadlock may result. To prevent deadlock from occurring, *Connex* is designed using careful analysis and following rules that force mutexes to be taken in a certain order when a thread must take multiple mutexes simultaneously.

However, because the Event and Receive threads already hold mutexes when invoking user callbacks, and because the *Connex* APIs that the user code can invoke may try to take other mutexes, deadlock may still result. Thus, to prevent user code to cause internal *Connex* threads to deadlock, we have created a concept called Exclusive Areas (EA) that follow rules that prevent deadlock. The more EAs that exist in a system, the more concurrency is allowed through *Connex* code. However, the more EAs that exist, the more restrictions on the *Connex* APIs that are allowed to be invoked in *Entity Listener* callbacks.

The [46.3 EXCLUSIVE\\_AREA QosPolicy \(DDS Extension\) on page 746](#) control how many EAs will be created by *Connex*. For a more detailed discussion on EAs and the restrictions on the use of *Connex* APIs within *Entity Listener* methods, please see [15.8.8 Exclusive Areas \(EAs\) on page 54](#).

# Chapter 68 Controlling CPU Core Affinity for RTI Threads

Two fields in the `DDS_ThreadSettings_t` structure (see [50.4.7 Thread Settings on page 939](#)) are related to CPU core affinity: **`cpu_list`** and **`cpu_rotation`**.

**Note:** Although `DDS_ThreadSettings_t` is used in the Event, Database, ReceiverPool, and AsynchronousPublisher QoS policies, **`cpu_list`** and **`cpu_rotation`** are only relevant in the [44.6 RECEIVER\\_POOL QoS Policy \(DDS Extension\) on page 723](#).

Consult the [RTI Connex Core Libraries Platform Notes](#) to see which architectures support tuning CPU affinity.

While most thread-related QoS settings apply to a single thread, the ReceiverPool QoS policy's thread-settings control *every* receive thread created. In this case, there are several schemes to map  $M$  threads to  $N$  processors; **`cpu_rotation`** controls which scheme is used.

The **`cpu_rotation`** determines how **`cpu_list`** affects processor affinity for thread-related QoS policies that apply to multiple threads. If **`cpu_list`** is empty, **`cpu_rotation`** is irrelevant since no affinity adjustment will occur. Suppose instead that **`cpu_list`** = {0,1} and that the middleware creates three receive threads: {A, B, C}. If **`cpu_rotation`** is set to `CPU_NO_ROTATION`, threads A, B and C will have the same processor affinities (0-1), and the OS will control thread scheduling within this bound.

CPU affinities are commonly denoted with a bitmask, where set bits represent allowed processors to run on. This mask is printed in hex, so a CPU affinity of 0-1 can be represented by the mask `0x3`.

If **`cpu_rotation`** is `CPU_RR_ROTATION`, each thread will be assigned in round-robin fashion to one of the processors in **`cpu_list`**; perhaps thread A to 0, B to 1, and C to 0. Note that the order in which internal middleware threads spawn is unspecified.

# Chapter 69 Configuring Thread Settings with XML

Table 69.1 XML Tags for ThreadSettings\_t describes the XML tags that you can use to configure thread settings. For more information on thread settings, see:

- [50.4.7 Thread Settings on page 939](#)
- The [RTI Connex Core Libraries Platform Notes](#)
- The API Reference HTML documentation (select **Modules**, **RTI Connex API Reference**, **Infrastructure Module**, **QoS Policies**, **Extended QoS Support**, **Thread Settings**)

Table 69.1 XML Tags for ThreadSettings\_t

Tags within <thread>	Description	Number of Tags Allowed
<cpu_list>	<p>Each &lt;element&gt; specifies a processor on which the thread may run.</p> <pre>&lt;cpu_list&gt;   &lt;element&gt;value&lt;/element&gt; &lt;/cpu_list&gt;</pre> <p>Only applies to platforms that support controlling CPU core affinity (see <a href="#">Chapter 68 Controlling CPU Core Affinity for RTI Threads on page 1191</a> and the <a href="#">RTI Connex Core Libraries Platform Notes</a>).</p>	0 or 1
<cpu_rotation>	<p>Determines how the CPUs in &lt;cpu_list&gt; will be used by the thread. The value can be either:</p> <ul style="list-style-type: none"> <li>• THREAD_SETTINGS_CPU_NO_ROTATION The thread can run on any listed processor, as determined by OS scheduling.</li> <li>• THREAD_SETTINGS_CPU_RR_ROTATION The thread will be assigned a CPU from the list in round-robin order.</li> </ul> <p>Only applies to platforms that support controlling CPU core affinity (see the <a href="#">RTI Connex Core Libraries Platform Notes</a>).</p>	0 or 1

**Table 69.1 XML Tags for ThreadSettings\_t**

Tags within <thread>	Description	Number of Tags Allowed
<mask>	<p>A collection of flags used to configure threads of execution. Not all of these options may be relevant for all operating systems. May include these bits:</p> <ul style="list-style-type: none"> <li>• STDIO</li> <li>• FLOATING_POINT</li> <li>• REALTIME_PRIORITY</li> <li>• PRIORITY_ENFORCE</li> </ul> <p>It can also be set to a combination of the above bits by using the “or” symbol ( ), such as STDIO FLOATING_POINT. Default: MASK_DEFAULT</p>	0 or 1
<priority>	<p>Thread priority. The value can be specified as an unsigned integer or one of the following strings.</p> <ul style="list-style-type: none"> <li>• THREAD_PRIORITY_DEFAULT</li> <li>• THREAD_PRIORITY_HIGH</li> <li>• THREAD_PRIORITY_ABOVE_NORMAL</li> <li>• THREAD_PRIORITY_NORMAL</li> <li>• THREAD_PRIORITY_BELOW_NORMAL</li> <li>• THREAD_PRIORITY_LOW</li> </ul> <p>When using an unsigned integer, the allowed range is platform-dependent. When thread priorities are configured using XML, the values are considered native priorities. Example:</p> <pre data-bbox="321 1213 899 1325">&lt;thread&gt;   &lt;mask&gt;STDIO FLOATING_POINT&lt;/mask&gt;   &lt;priority&gt;10&lt;/priority&gt;   &lt;stack_size&gt;THREAD_STACK_SIZE_DEFAULT&lt;/stack_size&gt; &lt;/thread&gt;</pre> <p>When the XML file is loaded using the Java API, the priority is a native priority, not a Java thread priority.</p>	0 or 1
<stack_size>	<p>Thread stack size, specified as an unsigned integer or set to the string THREAD_STACK_SIZE_DEFAULT. The allowed range is platform-dependent.</p>	0 or 1

## Chapter 70 User-Managed Threads

In certain scenarios, you may want full control over the internal threads created by your *Connex*t applications. For instance, in memory-constrained systems, applications may want to manage the resources required by internal *Connex*t threads. Also, you may want to use a different thread technology than the one *Connex*t incorporates by default (i.e., pthread on POSIX platforms).

*Connex*t can create the internal threads from the application layer via the abstract factory pattern. You can provide a *Connex*t application with a **ThreadFactory** implementation that *DomainParticipants* will use to create and delete all the threads.

The **ThreadFactory** interface exposes operations for creating and deleting threads. These operations are called on demand as *DomainParticipants* require new threads or need to delete existing ones.

The same **ThreadFactory** instance can be used by multiple *DomainParticipants*. To select which ThreadFactory to use, use the **set\_thread\_factory()** operation in the *DomainParticipantFactory*:

```
MyThreadFactory myThreadFactory; // Implements DDSThreadFactory
retcode = DDSTheParticipantFactory->set_thread_factory(&myThreadFactory);
```

Then you can create *DomainParticipants* using any of the available APIs (i.e. **create\_participant()**, **create\_participant\_from\_config()**, etc). A *DomainParticipant* will use the **ThreadFactory** object that is set in the *DomainParticipantFactory* at the time it is created and throughout its entire lifecycle. If a new ThreadFactory is set, existing *DomainParticipants* will not be affected; they will still use the same ThreadFactory with which they were created.

This feature is only available for the C/C++ APIs. For further information, please see the API Reference HTML documentation.

# Chapter 71 Unregistering Threads

If the logic of your application requires spawning new threads, and in those threads you are calling a *Connex* API such as **write()**, you may notice a memory growth.

To ensure that all the resources allocated in that thread are correctly released, remember to call **unregister\_thread()** right before exiting the thread.

Here is what the full API looks like:

```
DDS_ReturnCode_t DDS_DomainParticipantFactory_unregister_thread(DDS_
DomainParticipantFactory * self);
```

For more information, search for **DDS\_DomainParticipantFactory\_unregister\_thread** in the API Reference HTML documentation.

# Chapter 72 Identifying Threads Used by Connex

*Connex* uses multiple internal threads for sending and receiving data, maintaining internal state, and calling user code when events occur. Further details regarding *Connex*'s threading model can be found in [Part 11: Connex Threading Model on page 1180](#). This section explains how these threads can be identified in your system.

## 72.1 Checking Thread Names at the OS Level

On some systems, it is possible to check the internal name of RTI threads directly at the operating system level. Threads created by *Connex* will have RTI-specific thread names, unless otherwise stated in the [RTI Connex Core Libraries Platform Notes](#), which lists architectures that do not support setting thread names.

In general, thread names follow this pattern:

```
r<Module>[<Participant identifier>][<Thread index>][<Transport name>]<Task type>
```

Where:

- The maximum length for a thread name is 16, including the '\0'.
- **r** indicates this is a thread from RTI.
- The second and third characters identify the **<Module>**:

**Table 72.1 Module in the Thread Representation**

Module	Thread Representation
Core	Co
Transport	Tr

Module	Thread Representation
Security	Se
Distributed Logger	DI
Persistence Service	Ps
Database Integration Service	Ds
Web Integration Service	Ws
Monitor	Mo
Recording Service	Re
Routing Service	Rs

- **<Participant identifier>** is represented with five characters, as follows:
  - If **participant\_name** is set: the participant identifier will be the first three characters and the last two characters of the **participant\_name**.
  - If **participant\_name** is not set: the identifier is computed as **domain\_id** (three characters), **participant\_id** (two characters).
  - If **participant\_name** is not set and the **participant\_id** is set to -1 (default value): the participant identifier is computed as the last five digits of the **rtps\_instance\_id** in the participant GUID.
- **<Thread index>** - index used to distinguish among threads with the same name.

For example, there are several instantiations of the receive thread; the thread index is used to differentiate them:

```
rCo32265##00Rcv
rCo32265##01Rcv
rCo32265##02Rcv
rCo32265##03Rcv
rCo32265##04Rcv
```

- **<Transport name>** is represented with four characters:

**Table 72.2 Transport Name in the Thread Representation**

Transport Name	Thread Representation
Transmission Control Protocol version 4 (TCPv4)	TCP4
Datagram Transport Layer Security (DTLS)	DTLS

Transport Name	Thread Representation
Transport Layer Security (TLS)	TLS
Wide Area Network (WAN)	WAN
User Datagram Protocol version 4 (UDPv4)	UDP4
User Datagram Protocol version 6 (UDPv6)	UDP6

- **<taskType>** - the type of thread is represented with three characters:

**Table 72.3 Task Type in the Thread Representation**

Transport Name	Thread Representation
Event	Evt
Receive	Rcv
Database	Dtb
Asynchronous waitSet	AWs
Dispatcher	Dsp
Asynchronous batch flushing	ABF
Topic query publication	TQP
DNS tracker	DNS
Writer	Wri
Logger	Log
Control	Ctr
Server	Svr
Interface tracker	Itr
Discovery	Dis
Publication	Pub
Timer	Tim
Connection	Con

The details on checking the thread names depend on the operating system. The following is an example output from a publisher application running on VxWorks 6.9.4:

```
-> taskSpawn "test", 255, <floating_point_option>, 150000, publisher_main, 1, 100
value = 83748528 = 0x4fde6b0
-> i
```

```

[...]

```

Where `<floating_point_option>` is a numeric value that varies depending on the hardware. See [Enabling Floating Point Coprocessor in Kernel Tasks, in the RTI Connex Core Libraries Platform Notes](#).

In this example, the `i` command in VxWorks retrieves information about the running threads. The `>` at the end of the name (`rCoHelnt##>`) indicates that the full thread name could not be displayed, because it exceeds 10 characters. You can use the `ti` command in VxWorks (shown above), followed by the thread ID (TID), to retrieve information about a specific thread, including its full name (in this case, `rCoHelnt##00Rcv`).

The following is an example from running a subscriber on a Linux machine:

```

$ ./objs/x64Linux3gcc5.4.0/HelloWorld_subscriber
HelloWorld subscriber sleeping for 4 sec...
HelloWorld subscriber sleeping for 4 sec...
HelloWorld subscriber sleeping for 4 sec...
[...]
$ ps -eT | grep rC
22966 22967 pts/19    00:00:00 rCo32265####Dtb
22966 22968 pts/19    00:00:00 rCo32265####Evt
22966 22970 pts/19    00:00:00 rCo32265##00Rcv
22966 22971 pts/19    00:00:00 rCo32265##01Rcv
22966 22972 pts/19    00:00:00 rCo32265##02Rcv
22966 22973 pts/19    00:00:00 rCo32265##03Rcv
22966 22974 pts/19    00:00:00 rCo32265##04Rcv

```

**Note:** For transport threads, you have the option of setting your own thread name prefix, which substitutes the first three components (**r<Module>[<Participant identifier>]**) of the thread name with your own prefix. Setting your own thread name prefix allows you to add extra information to the transport thread, such as your own identifier for the threads or the *Topic* used. You can optionally set this prefix using the **thread\_name\_prefix** field in the transport (for example, in the [53.2.7 TCP/TLS Transport Properties on page 1065](#)).

Table 72.4 Example Thread Names shows names for the majority of threads created by *Connex*:

**Table 72.4 Example Thread Names**

Thread Information	Name	Fields	Example: Domain: 111 Participant Id : 22 ThreadIndex: 33 Topic: HelloWorld DataBase: Test Application Name: TestPersistence
Receive thread	rCo%5s###%02dRcv	Participant identifier, thread index	rCo11122##33Rcv

## 72.2 Checking Thread Names from the Call Stack

Thread names are only available in a subset of architectures. See the [RTI Connex Core Libraries Platform Notes](#) for which architectures support checking thread names at the OS level. This section lists the correspondence between *Connex* threads and the functions they run. You can use this information to identify *Connex* threads from the call stack, independently of your architecture. If you are using VxWorks or Integrity, see [72.1 Checking Thread Names at the OS Level on page 1196](#).

This is the correspondence between threads and the functions they run:

- **Database Thread:** RTIEventActiveDatabaseThread\_loop()
- **(Main) Event Thread:** RTIEventActiveGeneratorThread\_loop(). Note that this function is generic to all the event threads. That is, all of the event threads run RTIEventActiveGeneratorThread\_loop(), which detects and handles events. For this reason, it can be difficult to distinguish the Main Event Thread from other event threads (such as the Topic Query Publication Event Thread); however, to better make this distinction, you can check whether some (sub-)functions are called (for example, the subfunctions related to the Asynchronous Batch Flushing Event Thread and Topic Query Publication Event Thread below).
- **Receive Thread:** COMMENDActiveFacadeReceiver\_loop(), which calls to a different function depending on what transport is being used to get the (meta)data:
  - **Shared Memory:** NDDS\_Transport\_Shmem\_receive\_rEA()
  - **UDP:** NDDS\_Transport\_UDP\_receive\_rEA()
  - **TCP:** NDDS\_Transport\_TCP\_receive\_rEA()

- **Interface Tracking Thread:** RTIOSapiInterfaceTracker\_()
- **Transport-Specific Threads:**
  - **TCP Control Thread:** NDDS\_Transport\_TCPv4\_Plugin\_threadLoop()
  - **TCP Event Thread:** RTIEventActiveGeneratorThread\_loop() and NDDS\_Transport\_TCPv4\_Plugin\_clientOn<event\_name>()
- **Asynchronous Publishing Thread:** RTIEventJobDispatcherThread\_spawnedFnc()
- **Asynchronous Batch Flushing Event Thread:** RTIEventActiveGeneratorThread\_loop() and PRESPsWriter\_onFlushBatch()
- **Topic Query Publication Event Thread:** RTIEventActiveGeneratorThread\_loop() and PRESPsService\_onWriterServiceDispatchActiveTopicQueriesEvent()

For example, if you are on GNU/Linux, you can run the following command on gdb to get the call stack:

```
(gdb) thread apply all backtrace
```

The same information can be seen with Visual Studio. To see this information in Visual Studio, select Debug > Windows > Threads, then do Ctrl+D, T. You will need to add a breakpoint and start the application in debug mode.

## 72.3 Checking Thread Names Using the Worker's Name

*Connex*t uses the concept of a *worker* as an abstraction for threads. Workers are RTI-specific entities used internally to manage critical sections and to provide access to thread-specific storage. Most of the threads created by *Connex*t have an associated worker. In addition, user threads calling certain APIs from *Connex*t will have a worker associated with them. Workers are given a name when they are created. If you have the proper debug symbols, you can use the worker's name to identify the thread (on a debugger, for instance).

To check the workers' names, first locate these workers in the threads. You can do that by selecting a thread and printing its full backtrace. Another option is moving up and down through the frames on the thread's stack. The worker will be either a local variable or the last argument to one of the RTI functions. Here is an example using gdb on GNU/Linux to identify a thread with the method just described:

```
(gdb) info thread
  Id  Target Id          Frame
* 1   Thread 0x7ffff7fce700 (LWP 6801) "HelloWorld_publ" __clock_nanosleep (clock_
id=<optimized out>, flags=0, req=0x7ffffffffffcb20, rem=0x7ffffffffffcb30) at
../sysdeps/unix/sysv/linux/clock_nanosleep.c:48
  2   Thread 0x7ffff6ec1700 (LWP 6805) "HelloWorld_publ" pthread_cond_timedwait@@GLIBC_
2.3.2 () at ../sysdeps/unix/sysv/linux/x86_64/pthread_cond_timedwait.S:225
  3   Thread 0x7ffff66c0700 (LWP 6806) "HelloWorld_publ" pthread_cond_timedwait@@GLIBC_
2.3.2 () at ../sysdeps/unix/sysv/linux/x86_64/pthread_cond_timedwait.S:225
[...]
```

```
(gdb) thread 2
[Switching to thread 2 (Thread 0x7ffff6ec1700 (LWP 6805))]

(gdb) backtrace full
[...]
#3 0x000000000c6095b in RTIEventActiveDatabaseThread_loop (param=0x13fc8c0) at
ActiveDatabase.c:156
    timeStr = 0x7ffff6ec0dc0 "{0000003d,00000000}"
    t = 0x13fc8c0
    canBeDeleted = 0
    timeBuf = "{0000003d,00000000}"
    workerName = 0x1351cb0 "rDtb2081a9101"
    METHOD_NAME = 0x100a0d0 "RTIEventActiveDatabaseThread_loop"
[...]
```

As you can see in the example, workers follow the same naming convention as threads (in some cases, a shortened version of it). Workers associated with user threads use the following convention:

**U<threadId>**, where:

- **U** - indicator that this is a User Thread
- **<threadId>** - ID given to the thread by the OS

# Part 12: RTI Persistence Service

The material in this part of the manual describes *Persistence Service*. It saves DDS data samples so they can be delivered to subscribing applications that join the system at a later time—even if the publishing application has already terminated.

*Persistence Service* is not available on all platforms. See the [RTI Connex Core Libraries Platform Notes](#).

This section includes:

- [Introduction to RTI Persistence Service \(Chapter 73 on page 1206\)](#)
- [Configuring Persistence Service \(Chapter 74 on page 1207\)](#)
- [Running RTI Persistence Service \(Chapter 75 on page 1233\)](#)
- [Administering Persistence Service from a Remote Location \(Chapter 76 on page 1236\)](#)
- [Advanced Persistence Service Scenarios \(Chapter 77 on page 1242\)](#)

# Chapter 73 Introduction to RTI Persistence Service

*Persistence Service* is a *Connex*t application that saves DDS data samples to transient or permanent storage, so they can be delivered to subscribing applications that join the system at a later time—even if the publishing application has already terminated.

*Persistence Service* runs as a separate application; you can run it on the same node as the publishing application, the subscribing application, or some other node in the network.

When configured to run in PERSISTENT mode (<persistent\_storage> is used), *Persistence Service* can use the filesystem. For each persistent topic, it collects all the data written by the corresponding persistent *DataWriters* and stores them into persistent storage. See the *RTI Persistence Service Release Notes* for the list of platforms in which PERSISTENT mode is supported.

When configured to run in TRANSIENT mode (<persistent\_storage> is not used), *Persistence Service* stores the data in memory.

The following chapters assume you have a basic understanding of DDS terms such as *DomainParticipants*, *Publishers*, *DataWriters*, *Topics*, and Quality of Service (QoS) policies. For an overview of DDS terms, please see [Connex](#)t Communication Model (Chapter 3 on page 4). You should also have already read [Mechanisms for Achieving Information Durability and Persistence](#) (Chapter 21 on page 288).

# Chapter 74 Configuring Persistence Service

To use *Persistence Service*:

1. Modify your *Connex* applications.
  - The [47.9 DURABILITY QosPolicy on page 809](#) controls whether or not, and how, published DDS samples are stored by *Persistence Service* for delivery to late-joining *DataReaders*. See [21.5 Data Durability on page 304](#).
    - For each *DataWriter* whose data must be stored, set the Durability QosPolicy's *kind* to DDS\_PERSISTENT\_DURABILITY\_QOS or DDS\_TRANSIENT\_DURABILITY\_QOS.
    - For each *DataReader* that needs to receive stored data, set the Durability QosPolicy's *kind* to DDS\_PERSISTENT\_DURABILITY\_QOS or DDS\_TRANSIENT\_DURABILITY\_QOS.
  - Optionally, modify the [47.10 DURABILITY SERVICE QosPolicy on page 814](#), which can be used to configure *Persistence Service*.

By default, the History and ResourceLimits QosPolicies for a Persistence Service *DataReader* (PRSTDataReader) and Persistence Service *DataWriter* (PRSTDataWriter) with topic 'A' will be configured using the values specified in the XML file (unless you use the tag <use\_durability\_service> in the persistence group definition, see [74.8 Creating Persistence Groups on page 1220](#)). Setting the <use\_durability\_service> tag to true will cause the History and ResourceLimits QosPolicies for a PRSTDataReader and PRSTDataWriter to be configured using the [47.10 DURABILITY SERVICE QosPolicy on page 814](#) of the first-discovered *DataWriter* publishing 'A'. (For more information on the PRSTDataReader and PRSTDataWriter, see [21.5.1 RTI Persistence Service on page 305](#).)

2. Create a configuration file or edit an existing file, as described in [74.2 XML Configuration File on the next page](#).
3. Start *Persistence Service* with your configuration file, as described in [75.1 Starting Persistence Service on page 1233](#). You can start it on either application's node, or even an entirely different node (provided that node is included in one of the applications' `NDDS_DISCOVERY_PEERS` lists).

## 74.1 How to Load the Persistence Service XML Configuration

*Persistence Service* loads its XML configuration from multiple locations. This section presents the various approaches, listed in load order.

The first three locations only contain QoS Profiles and are inherited from *Connex* (see [Configuring QoS with XML \(Chapter 50 on page 905\)](#)).

- `$NDDSHOME/resource/xml/NDDS_QOS_PROFILES.xml`

This file contains the DDS default QoS values; it is loaded automatically if it exists. (*First to be loaded.*)

- File specified in the `NDDS_QOS_PROFILES` Environment Variable

The files (or XML strings) separated by semicolons referenced in this environment variable are loaded automatically.

- `<working directory>/USER_QOS_PROFILES.xml`

This file is loaded automatically if it exists.

The next locations are specific to *Persistence Service*.

- `<NDDSHOME>/resource/xml/RTI_PERSISTENCE_SERVICE.xml`

This file contains the default *Persistence Service* configurations; it is loaded if it exists. There are two default configurations: **default** and **defaultDisk**. The **default** configuration persists all the topics into memory. The **defaultDisk** configuration persists all the topics into files located in the current working directory.

- `<working directory>/USER_PERSISTENCE_SERVICE.xml`

This file is loaded automatically if it exists.

- File specified using the command line option, **-cfgFile**

The command-line option **-cfgFile** (see [Table 75.1 Persistence Service Command-Line Options](#)) can be used to specify a configuration file.

## 74.2 XML Configuration File

The configuration file uses XML format. Let's look at a very basic configuration file, just to get an idea of its contents. You will learn the meaning of each line as you read the rest of this section.

### Example Configuration File

```
<?xml version="1.0" encoding="ISO-8859-1"?>
<!-- A Configuration file may be used by several
      persistence services specifying multiple
      <persistence_service> entries
-->
<dds>
  <!-- QoS LIBRARY SECTION -->
  <qos_library name="QosLib1">
    <qos_profile name="QosProfile1">
      <datawriter_qos name="WriterQos1">
        <history>
          <kind>DDS_KEEP_ALL_HISTORY_QOS</kind>
        </history>
      </datawriter_qos>
      <datareader_qos name="ReaderQos1">
        <reliability>
          <kind>DDS_RELIABLE_RELIABILITY_QOS</kind>
        </reliability>
        <history>
          <kind>DDS_KEEP_ALL_HISTORY_QOS</kind>
        </history>
      </datareader_qos>
    </qos_profile>
  </qos_library>
  <!-- PERSISTENCE SERVICE SECTION -->
  <persistence_service name="Srv1">
    <!-- REMOTE ADMINISTRATION SECTION -->
    <administration>
      <domain_id>72</domain_id>
      <distributed_logger>
        <enabled>true</enabled>
      </distributed_logger>
    </administration>
    <!-- PERSISTENT STORAGE SECTION -->
    <persistent_storage>
      <filesystem>
        <directory>/tmp</directory>
        <file_prefix>PS</file_prefix>
      </filesystem>
    </persistent_storage>
    <!-- DOMAINPARTICIPANT SECTION -->
    <participant name="Part1">
      <domain_id>71</domain_id>
      <!-- PERSISTENCE GROUP SECTION -->
      <persistence_group name="PerGroup1" filter="*">
        <single_publisher>true</single_publisher>
        <single_subscriber>true</single_subscriber>
        <datawriter_qos base_name="QosLib1::QosProfile1"/>
        <datareader_qos base_name="QosLib1::QosProfile1"/>
      </persistence_group>
    </participant>
  </persistence_service>
</dds>
```

```
    </persistence_group>
  </participant>
</persistence_service>
</dds>
```

## 74.2.1 Configuration File Syntax

The configuration file must follow these syntax rules:

- The syntax is XML and the character encoding is UTF-8.
- Opening tags are enclosed in `<>`; closing tags are enclosed in `</>`.
- A value is a UTF-8 encoded string. Legal values are alphanumeric characters. All leading and trailing spaces are removed from the string before it is processed.

For example, "`<tag> value </tag>`" is the same as "`<tag>value</tag>`".

- All values are case-sensitive unless otherwise stated.
- Comments are enclosed as follows: `<!-- comment -->`.
- The root tag of the configuration file must be `<dds>` and end with `</dds>`.
- The primitive types for tag values are specified in [Table 74.1 Supported Tag Values](#).

Table 74.1 Supported Tag Values

Type	Format	Notes
DDS_Boolean	yes, 1, true, BOOLEAN_TRUE or DDS_BOOLEAN_TRUE: these all mean TRUE	Not case-sensitive
	no, 0, false, BOOLEAN_FALSE or DDS_BOOLEAN_FALSE: these all mean FALSE	
DDS_Enum	A string. Legal values are those listed in the C or Java API Reference HTML documentation.	Must be specified as a string. (Do not use numeric values.)
DDS_Long	-2147483648 to 2147483647 or 0x80000000 to 0x7fffffff or LENGTH_UNLIMITED or DDS_LENGTH_UNLIMITED	A 32-bit signed integer
DDS_UnsignedLong	0 to 4294967296 or 0 to 0xffffffff	A 32-bit unsigned integer
String	UTF-8 character string	All leading and trailing spaces are ignored between two tags

## 74.2.2 XML Validation

### 74.2.2.1 Validation at Run-Time

*Persistence Service* validates the input XML files using a builtin Document Type Definition (DTD). You can find a copy of the builtin DTD in `<NDDSHOME>a/resource/schema/rti_persistence_service.dtd`. (This is only a copy of what the *Persistence Service* core uses. Changing this file has no effect unless you specify its path with the DOCTYPE tag, described below.)

You can overwrite the builtin DTD by using the XML tag, `<!DOCTYPE>`. For example, the following indicates that *Persistence Service* must use a different DTD file to perform validation:

```
<!DOCTYPE dds SYSTEM
"/local/usr/rti/dds/modified_rtipersenceservice.dtd">
```

If you do not specify the DOCTYPE tag in the XML file, the builtin DTD is used.

The DTD path can be absolute, or relative to the application's current working directory.

### 74.2.2.2 Validation During Editing

*Persistence Service* provides DTD and XSD files that describe the format of the XML content. We recommend including a reference to one of these documents in the XML file that contains the persistence service's configuration—this provides helpful features in code editors such as Visual Studio

<sup>a</sup>See [Paths Mentioned in Documentation on page 1](#).

and Eclipse, including validation and auto-completion while you are editing the XML file. Including a reference to the XSD file in the XML documents provides stricter validation and better auto-completion than the corresponding DTD file.

The DTD and XSD definitions of the XML elements are in `<NDDSHOME>/resource/schema (rti_persistence_service.dtd and rti_persistence_service.xsd, respectively).`

To include a reference to the XSD document in your XML file, use the attribute `xsi:noNamespaceSchemaLocation` in the `<dds>` tag. For example (in the following, replace `<NDDSHOME>` with the *Connex* installation directory, see [Paths Mentioned in Documentation on page 1](#)):

```
<?xml version="1.0" encoding="UTF-8"?>
<dds xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:noNamespaceSchemaLocation=
"<NDDSHOME>/resource/schema/rti_persistence_service.xsd">
  ...
</dds>
```

To include a reference to the DTD document in your XML file, use the `<!DOCTYPE>` tag. For example (in the following, replace `<NDDSHOME>` with the *Connex* installation directory):

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE dds SYSTEM
"<NDDSHOME>/resource/schema/rti_persistence_service.dtd">
<dds>
  ...
</dds>
```

### 74.2.2.3 Skipping Element Validation

See [50.9.3 Skipping Element Validation: the must\\_interpret Attribute on page 948](#) for details.

## 74.3 QoS Configuration

Each persistence group and participant has a set of DDS QoSs. There are six tags:

- `<domain_participant_qos>`
- `<publisher_qos>`
- `<subscriber_qos>`
- `<topic_qos>`
- `<datawriter_qos>`
- `<datareader_qos>`

Each QoS is identified by a name. The QoS can inherit its values from other QoSs described in the XML file. For example:

```
<datawriter_qos name="DerivedWriterQos" base_name="Lib::BaseWriterQos">
  <history>
    <kind>DDS_KEEP_ALL_HISTORY_QOS</kind>
  </history>
</datawriter_qos>
```

In the above example, the writer QoS named 'DerivedWriterQos' inherits the values from the writer QoS 'BaseWriterQos' contained in the library 'Lib'. The HistoryQosPolicy **kind** is set to DDS\_KEEP\_ALL\_HISTORY\_QOS.

Each XML tag with an associated name can be uniquely identified by its fully qualified name in C++ style. For more information on tags, see [Configuring QoS with XML \(Chapter 50 on page 905\)](#)

The persistence groups and participants can use QoS libraries and profiles to configure their QoS values. For example:

```
<dds>
  <!-- QoS LIBRARY SECTION -->
  <qos_library name="QosLib1">
    <qos_profile name="QosProfile1">
      <datawriter_qos name="WriterQos1">
        <history>
          <kind>DDS_KEEP_ALL_HISTORY_QOS</kind>
        </history>
      </datawriter_qos>
    </qos_profile>
  </qos_library>
  <!-- PERSISTENCE SERVICE SECTION -->
  <persistence_service name="Srv1">
    ...
  <!-- PERSISTENCE GROUP SECTION -->
  <persistence_group name="PerGroup1" filter="*">
    <single_publisher>true</single_publisher>
    <single_subscriber>true</single_subscriber>
    <datawriter_qos base_name="QosLib1::QosProfile1"/>
  </persistence_group>
</persistence_service>
</dds >
```

For more information about QoS libraries and profiles see [Configuring QoS with XML \(Chapter 50 on page 905\)](#).

## 74.4 Configuring the Persistence Service Application

Each execution of the *Persistence Service* application is configured using the content of a tag: `<persistence_service>`. When you start *Persistence Service* (described in [75.1 Starting Persistence Service on page 1233](#)), you must specify which `<persistence_service>` tag to use to configure the service.

For example:

```
<dds>
  <persistence_service name="Srv1">
    ...
```

```
</persistence_service>  
</dds>
```

If you do not specify a service name when you start *Persistence Service*, the service will print the list of available configurations and then exit.

Because a configuration file may contain multiple `<persistence_service>` tags, one file can be used to configure multiple *Persistence Service* executions.

[Table 74.2 Persistence Service Application Tags](#) lists the tags you can specify for a persistence service. Notice that `<participant>` is required. For default values, please see the API Reference HTML documentation.

Table 74.2 Persistence Service Application Tags

Tags within <persistence_service>	Description	Number of Tags Allowed
<administration>	Enables and configures remote administration. See <a href="#">74.5 Configuring Remote Administration below</a> .	0 or 1
<annotation>	Provides a description for the persistence service configuration. Example: <pre>&lt;annotation&gt;   &lt;documentation&gt;     Persists in the file system all topics     published with PERSISTENT durability   &lt;/documentation&gt; &lt;/annotation&gt;</pre>	0 or 1
<purge_samples_after_acknowledgment>	A DDS_Boolean that indicates whether or not a PRSTDataWriter will purge a DDS sample from its cache once it is acknowledged by all the matching/active <i>DataReaders</i> and all the Durable Subscriptions. Default: 0 See <a href="#">74.9 Configuring Durable Subscriptions in Persistence Service on page 1226</a> .	0 or 1
<participant>	For each <participant> tag, <i>Persistence Service</i> creates two <i>DomainParticipants</i> on the same domain ID: one to subscribe to changes and one to publish changes. There may be more Participant pairs created when there are multiple versions of a type (see <a href="#">74.13 Support for Extensible Types on page 1230</a> ). The QoS values used to configure both <i>DomainParticipants</i> are the same, except for: <ul style="list-style-type: none"> <li>The <b>participant_id</b> in the <a href="#">44.9 WIRE_PROTOCOL QoSPolicy (DDS Extension) on page 730</a>. If <b>participant_id</b> is not -1 (the default value, which means automatic selection), <i>Persistence Service</i> uses <b>participant_id</b> for the first <i>DomainParticipant</i> and <b>participant_id+1</b> for the second <i>DomainParticipant</i>.</li> <li>The TCP server ports are configured with the properties <b>dds.transport.tcp.server_bind_port</b> and <b>dds.transport.tcp.public_address</b>. See <a href="#">53.2.7 TCP/TLS Transport Properties on page 1065</a>.</li> </ul>	1 or more (required)
<persistent_storage>	When this tag is present, the topic data will be persisted to disk. See <a href="#">74.6 Configuring Persistent Storage on the next page</a> .	0 or 1
<synchronization>	Enables synchronization in redundant persistence service instances. See <a href="#">74.10 Synchronizing of Persistence Service Instances on page 1228</a> . Default: Synchronization is not enabled	0 or 1

## 74.5 Configuring Remote Administration

You can create a *Connex* application that can remotely control *Persistence Service*. The **<administration>** tag is used to enable remote administration and configure its behavior.

By default, remote administration is turned off in *Persistence Service*.

When remote administration is enabled, *Persistence Service* will create a *DomainParticipant*, *Publisher*, *Subscriber*, *DataWriter*, and *DataReader*. These *Entities* are used to receive commands and send responses. You can configure these entities with QoS tags within the **<administration>** tag.

[Table 74.3 Remote Administration Tags](#) lists the tags allowed within **<administration>** tag. Notice that the **<domain\_id>** tag is required.

For more details, please see [Administering Persistence Service from a Remote Location \(Chapter 76 on page 1236\)](#).

**Note:** The command-line options used to configure remote administration take precedence over the XML configuration (see [Table 75.1 Persistence Service Command-Line Options](#)).

**Table 74.3 Remote Administration Tags**

Tags within <administration>	Description	Number of Tags Allowed
<datareader_qos>	Configures the <i>DataReader</i> QoS for remote administration. If the tag is not defined, <i>Persistence Service</i> will use the DDS defaults with the following changes: <code>reliability.kind = DDS_RELIABLE_RELIABILITY_QOS</code> (this value cannot be changed) <code>history.kind = DDS_KEEP_ALL_HISTORY_QOS</code> <code>resource_limits.max_samples = 32</code>	0 or 1
<datawriter_qos>	Configures the <i>DataWriter</i> QoS for remote administration. If the tag is not defined, <i>Persistence Service</i> will use the DDS defaults with the following changes: <code>history.kind = DDS_KEEP_ALL_HISTORY_QOS</code> <code>resource_limits.max_samples = 32</code>	0 or 1
<distributed_logger>	Configures <i>RTI Distributed Logger</i> .	0 or 1
<domain_id>	Specifies which domain ID <i>Persistence Service</i> will use to enable remote administration.	1 (required)
<domain_participant_qos>	Configures the <i>DomainParticipant</i> QoS for remote administration. If the tag is not defined, <i>Persistence Service</i> will use the DDS defaults.	0 or 1
<publisher_qos>	Configures the <i>Publisher</i> QoS for remote administration. If the tag is not defined, <i>Persistence Service</i> will use the DDS defaults.	0 or 1
<subscriber_qos>	Configures the <i>Subscriber</i> QoS for remote administration. If the tag is not defined, <i>Persistence Service</i> will use the DDS defaults.	0 or 1

## 74.6 Configuring Persistent Storage

The <**persistent\_storage**> tag is used to persist DDS samples into permanent storage. If the <**persistent\_storage**> tag is not specified, the service will operate in TRANSIENT mode and all the data will be kept in memory. Otherwise, the persistence service will operate in PERSISTENT mode and all the topic data will be stored on the filesystem.

[Table 74.4 Persistent Storage tags](#) lists the tags that you can specify in <**persistent\_storage**>.

Table 74.4 Persistent Storage tags

Tags within <persistent_ storage>	Description	Number of Tags Allowed
<filesystem>	When this tag is present, the topic data will be persisted into files. This tag is required if <external_database> is not specified. See <a href="#">Table 74.5 Filesystem tags</a> .	0 or 1
<restore>	This DDS_Boolean (see <a href="#">Table 74.1 Supported Tag Values</a> ) indicates if the topic data associated with a previous execution of the persistence service must be restored or not. If the topic data is not restored, it will be deleted from the persistent storage. Restoring the topic data associated with a previous execution of the <i>Persistence Service</i> requires using the same configuration name (-cfgName; see <a href="#">75.1 Starting Persistence Service on page 1233</a> ) that was used to persist the data. Default: 1	0 or 1
<type_object_max_serialized_length>	Defines the length in bytes of the database column used to store the TypeObjects associated with PRSTDataWriters and PRSTDataReader. For additional information on TypeObjects, see the <a href="#">RTI Connext Core Libraries Extensible Types Guide</a> . Default: 10488576	0 or 1

Table 74.5 Filesystem tags

Tags within <filesystem>	Description	Number of Tags Allowed
<directory>	Specifies the directory of the files in which topic data will be persisted. There will be one file per PRSTDataWriter-PRSTDataReader pair. The directory must exist; otherwise the service will report an error upon start up. Default: current working directory	0 or 1
<file_prefix>	A name prefix associated with all the files created by <i>Persistence Service</i> . Default: PS	0 or 1

Table 74.5 Filesystem tags

Tags within <filesystem>	Description	Number of Tags Allowed
<journal_mode>	<p>Sets the journal mode of the persistent storage. This tag can take these values:</p> <ul style="list-style-type: none"> <li>DELETE: Deletes the rollback journal at the conclusion of each transaction.</li> <li>TRUNCATE: Commits transactions by truncating the rollback journal to zero-length instead of deleting it.</li> <li>PERSIST: Prevents the rollback journal from being deleted at the end of each transaction. Instead, the header of the journal is overwritten with zeros.</li> <li>MEMORY: Stores the rollback journal in volatile RAM. This saves disk I/O.</li> <li>WAL: Uses a write-ahead log instead of a rollback journal to implement transactions.</li> <li>OFF: Completely disables the rollback journal. If the application crashes in the middle of a transaction when the OFF journaling mode is set, the files containing the DDS samples will very likely be corrupted.</li> </ul> <p>Default: WAL</p>	0 or 1
<synchronization>	<p>Determines the level of synchronization with the physical disk.</p> <p>This tag can take three values:</p> <ul style="list-style-type: none"> <li>FULL: Every DDS sample is written into physical disk as <i>Persistence Service</i> receives it.</li> <li>NORMAL: DDS samples are written into disk at critical moments.</li> <li>OFF: No synchronization is enforced. Data will be written to physical disk when the OS flushes its buffers.</li> </ul> <p>Default: NORMAL</p>	0 or 1
<trace_file>	<p>Specifies the name of the trace file for debugging purposes. The trace file contains information about all SQL statements executed by the persistence service.</p> <p>Default: No trace file is generated</p>	0 or 1
<vacuum>	<p>Sets the auto-vacuum status of the storage. This tag can take these values:</p> <ul style="list-style-type: none"> <li>NONE: When data is deleted from the storage files, the files remain the same size.</li> <li>FULL: The storage files are compacted every transaction.</li> </ul> <p>Default: FULL</p>	0 or 1

## 74.7 Configuring Participants

An XML <persistence\_service> tag will contain a set of <participants>. The persistence service will persist topics published in the domainIDs associated with these participants. For example:

```
<persistence_service name="Srv1">
  <participant name="Part1">
    <domain_id>71</domain_id>
    ...
  </participant>
  <participant name="Part2">
    <domain_id>72</domain_id>
```

```

...
</participant>
</persistence_service>

```

Using the above example, the persistence service will create two pairs of *DomainParticipants* on DDS domains 71 and 72, respectively. In each pair, one *DomainParticipant* is used to receive data and the other to publish.

After the *DomainParticipants* are created, the persistence service will monitor the discovery traffic, looking for topics to persist.

Notice that in some cases there may be more than one pair of *DomainParticipants* per domain when there are multiple versions of a type for a given topic. (See [74.13 Support for Extensible Types on page 1230](#).)

The `<domain_id>` tag can be specified alternatively as an attribute of `<participant>`. For example:

```

<persistence_service name="Srv1">
  <participant name="Part1" domain_id="71">
    ...
  </participant>
</persistence_service>

```

[Table 74.6 Participant Tags](#) describes the participant tags. Notice that `<persistence_group>` is required.

**Table 74.6 Participant Tags**

Tags within <code>&lt;participant&gt;</code>	Description	Number of Tags Allowed
<code>&lt;domain_id&gt;</code>	Domain ID associated with the Participant. The domain ID can be specified as an attribute of the participant tag. Default: 0	0 or 1
<code>&lt;durable_subscriptions&gt;</code>	Configures a set of Durable Subscriptions for a given topic. This is a sequence of <code>&lt;element&gt;</code> tags, each of which has a <code>&lt;name&gt;</code> (role name in <code>DDS_EndpointGroup_t</code> ), a <code>&lt;topic_name&gt;</code> , and a <code>&lt;quorum_count&gt;</code> (quorum in <code>DDS_EndpointGroup_t</code> ). For example:  <pre> &lt;durable_subscriptions&gt;   &lt;element&gt;     &lt;name&gt;DurSub1&lt;/name&gt;     &lt;topic_name&gt;Example MyType&lt;/topic_name&gt;     &lt;quorum_count&gt;2&lt;/quorum_count&gt;   &lt;/element&gt;   &lt;element&gt;     &lt;name&gt;DurSub2&lt;/name&gt;     &lt;topic_name&gt;Example MyType&lt;/topic_name&gt;   &lt;/element&gt; &lt;/durable_subscriptions&gt; </pre> Default: Empty list See <a href="#">74.9 Configuring Durable Subscriptions in Persistence Service on page 1226</a> for additional information	0 or 1

**Table 74.6 Participant Tags**

Tags within <participant>	Description	Number of Tags Allowed
<domain_participant_qos>	Participant QoS. Default: DDS defaults	0 or 1
<persistence_group>	A persistence group describes a set of topics whose data that must be persisted by the persistence service.	1 or more (required)

## 74.8 Creating Persistence Groups

The topics that must be persisted in a specific domain ID are specified using <persistence\_group> tags. A <persistence\_group> tag defines a set of topics identified by a POSIX expression.

For example:

```
<participant name="Part1">
  <domain_id>71</domain_id>
  <persistence_group name="PerGroup1" filter="H*">
    ...
  </persistence_group>
</participant>
```

In the above example, the persistence group 'PerGroup1' is associated with all the topics published in DDS domain 71 whose name starts with 'H'.

When a participant discovers a topic that matches a persistence group, it will create a PRSTDataReader and a PRSTDataWriter. The PRSTDataReader and PRSTDataWriter will be configured using the QoS policies associated with the persistence group. The DDS samples received by the PRSTDataReader will be persisted in the queue of the corresponding PRSTDataWriter.

A <participant> tag can contain multiple persistence groups; the set of topics that each one represents can intersect.

[Table 74.7 Persistence Group Tags](#) further describes the persistence group tags. For default values, please see the API Reference HTML documentation.

Table 74.7 Persistence Group Tags

Tags within <persistence_group>	Description	Number of Tags Allowed
<allow_durable_subscriptions>	A DDS_Boolean (see <a href="#">Table 74.1 Supported Tag Values</a> ) that enables support for durable subscriptions in the PRSTDataWriters created in a persistence group. When Durable Subscriptions are not required, setting this property to 0 will increase performance. Default: 1	0 or 1
<content_filter>	Content filter topic expression. A persistence group can subscribe to a specific set of data based on the value of this expression. A filter expression is similar to the WHERE clause in SQL. For more information on the syntax, please see the API Reference Documentation (from the Modules page, select RTI <i>Connex</i> API Reference, Queries and Filters Syntax). Default: no expression	0 or 1
<datareader_qos>	PRSTDataReader QoS <sup>1</sup> . See <a href="#">74.8.1 QoSs on page 1223</a> . Default: DDS defaults	0 or 1
<datawriter_qos>	PRSTDataWriter QoS <sup>2</sup> . See <a href="#">74.8.1 QoSs on page 1223</a> . Default: DDS defaults	0 or 1
<deny_filter>	Specifies a list of POSIX expressions separated by commas that describe the set of topics to be denied in the persistence group. This "black" list is applied to the topics that pass the filter specified with the <filter> tag Default: *	0 or 1
<filter>	Specifies a list of POSIX expressions separated by commas that describe the set of topics associated with the persistence group. The filter can be specified as an attribute of <persistence_group> as well. Default: *	0 or 1
<memory_management>	This flag configures the memory allocation policy for DDS samples in PRSTDataReaders and PRSTDataWriters. See <a href="#">74.8.4 Memory Management on page 1225</a> .	0 or 1
<propagate_dispose>	A DDS_Boolean (see <a href="#">Table 74.1 Supported Tag Values</a> ) that controls whether or not the persistence service propagates dispose messages from <i>DataWriters</i> to <i>DataReaders</i> . When this tag is set to true, <i>Persistence Service</i> propagates dispose samples, but it doesn't propagate the key value for those dispose samples. Therefore, a <i>DataReader</i> receiving samples from the <i>Persistence Service</i> may not be able to access the key value for an instance if the first and only sample that it received is a dispose sample of that instance. Default: 1	0 or 1
<propagate_source_timestamp>	A DDS_Boolean (see <a href="#">Table 74.1 Supported Tag Values</a> ). When this tag is 1, the DDS data samples sent by the PRSTDataWriters preserve the source timestamp that was associated with them when they were published by the original <i>DataWriter</i> . Default: 0	0 or 1

<sup>1</sup>These fields cannot be set and are assigned automatically: protocol.virtual\_guid, protocol.rtps\_object\_id, durability.kind.

<sup>2</sup>These fields cannot be set and are assigned automatically: protocol.virtual\_guid, protocol.rtps\_object\_id, durability.kind.

Table 74.7 Persistence Group Tags

Tags within <persistence_group>	Description	Number of Tags Allowed
<propagate_unregister>	A DDS_Boolean (see <a href="#">Table 74.1 Supported Tag Values</a> ) that controls whether or not the persistence service propagates unregister messages from <i>DataWriters</i> to <i>DataReaders</i> . Default: 0	0 or 1
<publisher_qos>	Publisher QoS. See <a href="#">74.8.1 QoSs on the next page</a> . Default: DDS defaults	0 or 1
<reader_checkpoint_frequency>	This property controls how often (expressed as a number of DDS samples) the PRSTDataReader state is stored in the database. The PRSTDataReaders are the <i>DataReaders</i> created by the persistence service. A high frequency will provide better performance. However, if the persistence service is restarted, it may receive some duplicate DDS samples. The persistence service will send these duplicates DDS samples on the wire but they will be filtered by the <i>DataReaders</i> and they will not be propagated to the application. This property is only applicable when the persistence service operates in persistent mode (the <persistent_storage> tag is present). Default: 1	0 or 1
<single_publisher>	A DDS_Boolean (see <a href="#">Table 74.1 Supported Tag Values</a> ) that indicates if the persistence service should create one Publisher per persistence group or one <i>Publisher</i> per PRSTDataWriter inside the persistence group. See <a href="#">74.8.3 Sharing a Publisher/Subscriber on page 1225</a> . Default: 1	0 or 1
<single_subscriber>	A DDS_Boolean (see <a href="#">Table 74.1 Supported Tag Values</a> ) that indicates if the persistence service should create one Subscriber per persistence group or one <i>Subscriber</i> per PRSTDataReader in the persistence group. See <a href="#">74.8.3 Sharing a Publisher/Subscriber on page 1225</a> . Default: 1	0 or 1
<subscriber_qos>	Subscriber QoS. See <a href="#">74.8.1 QoSs on the next page</a> . Default: DDS defaults	0 or 1
<topic_qos>	Topic QoS. See <a href="#">74.8.1 QoSs on the next page</a> . Default: DDS defaults	0 or 1
<use_durability_service>	A DDS_Boolean (see <a href="#">Table 74.1 Supported Tag Values</a> ) that indicates if the HISTORY and RESOURCE_LIMITS QoS policy of the PRSTDataWriters and PRSTDataReaders should be configured based on the DURABILITY_SERVICE value of the discovered DataWriters. See <a href="#">74.8.2 DurabilityService QoS Policy on page 1224</a> Default: 0	0 or 1
<writer_ack_period>	Controls how often (expressed in milliseconds) DDS samples are marked as ACK'd in the database by the PRSTDataWriter. Default: 0	0 or 1
<writer_checkpoint_period>	Controls how often (expressed in milliseconds) transactions are committed for a PRSTDataWriter. A value of 0 indicates that transactions will be committed immediately. This is the recommended setting to avoid losing data in the case of an unexpected error in Persistence Service and/or the underlying hardware/software infrastructure. For applications that can tolerate some data losses, setting this tag to a value greater than 0 will increase performance. Default: 0	0 or 1

Table 74.7 Persistence Group Tags

Tags within <persistence_group>	Description	Number of Tags Allowed
<writer_checkpoint_volume>	<p>Controls how often (expressed as a number of DDS samples) transactions are committed for a PRSTDataWriter.</p> <p>A value of 1 indicates that DDS samples will be persisted by the PRSTDataWriters immediately. This is the recommended setting to avoid losing data in the case of an unexpected error in persistence service and/or the underlying hardware/software infrastructure.</p> <p>For application that can tolerate some data losses, setting this tag to a value greater than 1 will increase performance.</p> <p>Default: 1</p>	0 or 1
<late_joiner_read_batch>	<p>Defines how many DDS samples will be pre-fetched by a PRSTDataWriter to satisfy requests from late-joiners.</p> <p>When a <i>DataReader</i> requests DDS samples from a PRSTDataWriter by sending a NACK message, the PRSTDataWriter may retrieve additional DDS samples from the database to minimize disk access.</p> <p>This parameter determines that amount of DDS samples that will be retrieved preemptively from the database by the PRSTDataWriter.</p> <p>Default: 20000</p>	0 or 1
<sample_logging>	<p>This tag can be used to enable and configure a DDS sample log for the PRSTDataWriters in a persistence group. A DDS sample log is a buffer of DDS samples on disk that, when used in combination with delegate reliability, allow decoupling the original <i>DataWriters</i> from slow <i>DataReaders</i>.</p> <p>For additional information on the DDS sample log, see <a href="#">77.3 Scenario: Slow Consumer on page 1245</a>.</p> <p>Default: DDS sample log is disabled</p>	0 or 1
<writer_in_memory_state>	<p>A <i>DDS_Boolean</i> (see <a href="#">Table 74.1 Supported Tag Values</a>) that determines how much state will be kept in memory by the PRSTDataWriters in order to avoid accessing the persistent storage.</p> <p>The property is only applicable when the persistence service operates in persistent mode (the &lt;persistent_storage&gt; tag is present).</p> <p>If this property is 1, the PRSTDataWriters will keep a copy of all the instances in memory. They will also keep a fixed state overhead of 24 bytes per DDS sample. This mode provides the best performance. However, the restore operation will be slower and the maximum number of DDS samples that a PRSTDataWriter can manage will be limited by the available physical memory.</p> <p>If this property is 0, all the state will be kept in the underlying persistent storage. In this mode, the maximum number of DDS samples that a PRSTDataWriter can manage will not be limited by the available physical memory.</p> <p>Default: If the <i>HistoryQosPolicy</i>'s kind is <i>KEEP_LAST</i> or the <i>ResourceLimitsQosPolicy</i>'s <i>max_samples</i> != <i>DDS_UNLIMITED_LENGTH</i>, the default is 1. Otherwise, the default is 0.</p>	0 or 1
<use_wait_set>	<p>A <i>DDS_Boolean</i> (see <a href="#">Table 74.1 Supported Tag Values</a>) that indicates if <i>Persistence Service</i> will use Waitsets or Listeners to read data from the PRSTDataReaders of the group.</p> <p>By default, the usage of Waitsets is disabled. With this configuration, <i>Persistence Service</i> uses the <b>on_data_available()</b> listener callback to take the data from the PRSTDataReaders within the persistence group. The write operation in a PRSTDataWriter is called within the listener callback.</p> <p>When Waitsets are enabled, <i>Persistence Service</i> will use them to read the data:</p> <p>If &lt;single_subscriber&gt; is set to 1, there will be a single Waitset and a read thread shared across all the PRSTDataReaders in the group.</p> <p>If &lt;single_subscriber&gt; is set to 0, there will be a Waitset and a read thread per PRSTDataReader in the group.</p> <p>The write operation in a PRSTDataWriter is called by the read thread associated with the PRSTDataReader.</p> <p>Default: 0</p>	0 or 1

## 74.8.1 QoSs

When a persistence service discovers a topic 'A' that matches a specific persistence group, it creates a reader (known as 'PRSTDataReader') and writer ('PRSTDataWriter') to persist that topic. The QoSs

associated with these readers and writers, as well as the corresponding publishers and subscribers, can be configured inside the persistence group using QoS tags.

For example:

```
<participant name="Part1">
  <domain_id>71</domain_id>
  <persistence_group name="PerGroup1" filter="*">
    ...
    <publisher_qos base_name="QosLib1::PubQos1"/>
    <subscriber_qos base_name="QosLib1::SubQos1"/>
    <datawriter_qos base_name="QosLib1::WriterQos1"/>
    <datareader_qos base_name="QosLib1::ReaderQos1"/>
    ...
  </persistence_group>
</participant>
```

For instance, the number of DDS samples saved by *Persistence Service* is configurable through the [47.12 HISTORY QoS Policy on page 818](#) of the PRSTDataWriters.

If a QoS tag is not specified, the persistence service will use the corresponding DDS default values ([74.8.2 DurabilityService QoS Policy below](#) describes an exception to this rule).

#### 74.8.1.1 DataRepresentation QoS Policy

The PRSTDataReader's DataRepresentation QoS Policy may contain either XCDR\_DATA\_REPRESENTATION or XCDR2\_DATA\_REPRESENTATION, but not both. The PRSTDataReader and PRSTDataWriter of a given topic must have identical DataRepresentation QoS Policy values. See [47.3 DATA\\_REPRESENTATION QoS Policy on page 780](#).

### 74.8.2 DurabilityService QoS Policy

The [47.10 DURABILITY SERVICE QoS Policy on page 814](#) associated with a *DataWriter* is used to configure the HISTORY and the RESOURCE\_LIMITS associated with the PRSTDataReaders and PRSTDataWriters.

By default, the HISTORY and RESOURCE\_LIMITS of a PRSTDataReader and *PRSTDataWriter* with topic 'A' will be configured using the values specified in the XML file used to configure *Persistence Service*. To overwrite those values and use the values in the [47.10 DURABILITY SERVICE QoS Policy on page 814](#) of the first discovered *DataWriter* publishing 'A', you can use the tag `<use_durability_service>` in the persistence group definition:

```

<participant name="Part1">
  <domain_id>71</domain_id>
  <persistence_group name="PerGroup1" filter="*">
    ...
    <use_durability_service/>1</ use_durability_service>
    ...
  </persistence_group>
</participant>

```

### 74.8.3 Sharing a Publisher/Subscriber

By default, the PRSTDataWriters and PRSTDataReaders associated with a persistence group will share the same Publisher and Subscriber.

To associate a different Publisher and Subscriber with each PRSTDataWriter and PRSTDataReader, use the tags `<single_publisher>` and `<single_subscriber>`, as follows:

```

<participant name="Part1">
  <domain_id>71</domain_id>
  <persistence_group name="PerGroup1" filter="*">
    ...
    <single_publisher/>0</single_publisher>
    <single_subscriber/>0</single_subscriber>
    ...
  </persistence_group>
</participant>

```

### 74.8.4 Memory Management

The DDS samples received and stored by the PRSTDataReaders and PRSTDataWriters are in serialized form.

The serialized size of a DDS sample is the number of bytes required to send the DDS sample on the wire. The maximum serialized size of a DDS sample is the number of bytes that the largest DDS sample for a given type requires on the wire.

By default, the PRSTDataReaders and PRSTDataWriters created by the persistence service try to allocate multiple DDS samples to their maximum serialized size. This may cause memory allocation issues when the maximum serialized size is significantly large.

For PRSTDataReaders, the number of DDS samples in the *DataReader's* queues can be controlled using the QoS values `resource_qos.resource_limits.max_samples` and `resource_qos.resource_limits.initial_samples`.

The PRSTDataWriters keep a cache of DDS samples so that they do not have to access the database every time. The minimum size of this cache is 32 DDS samples.

In addition, each PRSTDataWriter keeps an additional DDS sample called the DB sample, which is used to move information from the *DataWriter* cache to the database and vice versa

The `<memory_management>` tag in a persistence group can be used to control the memory allocation policy for the DDS samples created by PRSTDataReaders and PRSTDataWriters in the persistence group.

[Table 74.8 Memory Management Tags](#) describes the memory management tags.

**Table 74.8 Memory Management Tags**

Tags within <code>&lt;memory_management&gt;</code>	Description	Number of Tags Allowed
<code>&lt;persistent_sample_buffer_max_size&gt;</code>	<p>This tag is used to control the memory associated with the DB sample in a PRSTDataWriter. The persistence service will not be able to store a DDS sample into persistent storage if the serialized size is greater than this value. Therefore, this parameter must be used carefully.</p> <p>Default: LENGTH_UNLIMITED (DB sample is allocated to the maximum size).</p>	0 or 1
<code>&lt;pool_sample_buffer_max_size&gt;</code>	<p>This tag applies to both PRSTDataReaders and PRSTDataWriters. Its value determines the maximum size (in bytes) of the buffers that will be pre-allocated to store the DDS samples. If the space required for a new DDS sample is greater than this size, the persistence service will allocate the memory dynamically to the exact size required by the DDS sample.</p> <p>This parameter is used to control the memory allocated for the DDS samples in the PRSTDataReaders queues and the PRSTDataWriters caches.</p> <p>The size of the DB sample in the PRSTDataWriters is controlled by the value of the tag <code>&lt;persistent_sample_buffer_max_size&gt;</code>.</p> <p>Default: 4096</p>	0 or 1

## 74.9 Configuring Durable Subscriptions in Persistence Service

This section assumes you are familiar with the concept of [31.13 Required Subscriptions on page 424](#).

A Durable Subscription is a Required Subscription where DDS samples are stored and forwarded by *Persistence Service*.

There are two ways to create a Durable Subscriptions:

1. Programmatically using a *DomainParticipant* API:

A subscribing application can register a Durable Subscription by providing the topic name and the durable subscription information, consisting of the Durable Subscription **name** (`role_name` in `DDS_EndpointGroup_t`) and the **quorum\_count** (`quorum_count` in `DDS_EndpointGroup_t`). To register or delete a Durable Subscription, use the *DomainParticipant's* `register_durable_subscription()` and `delete_durable_subscription()` operations, respectively (see [Table 16.3 DomainParticipant Operations](#)). The Durable Subscription information is propagated via a built-in topic to *Persistence Service*.

2. Preconfigure *Persistence Service* with a set of Durable Subscriptions:

*Persistence Service* can be (pre-)configured with a list of Durable Subscriptions using the **< durable\_subscriptions >** XML tag under **< participant >**.

```
<participant name="Participant">
  ...
  <durable_subscriptions>
    <element>
      <name>Logger</name>
      <topic_name>Track</topic_name>
      <quorum_count>2</quorum_count>
    </element>
    <element>
      <name>Processor</name>
      <topic_name>Track</topic_name>
      <quorum_count>1</quorum_count>
    </element>
  </durable_subscriptions>
</participant>
```

After registering or configuring the persistence service with specific Durable Subscriptions, the persistence service will keep DDS samples until they are acknowledged by all the required Durable Subscriptions. In the above example, the DDS samples must be acknowledged by two *DataReaders* that belong to the “Logger” Durable Subscription and one *DataReader* belonging to the “Processor” Durable Subscription.

## 74.9.1 DDS Sample Memory Management With Durable Subscriptions

The maximum number of DDS samples that will be kept in a PRSTDataWriter queue is determined by the value of **< resource\_limits > < max\_samples >** in the **< writer\_qos >** used to configure the PRSTDataWriter.

By default, a PRSTDataWriter configured with KEEP\_ALL **< history > < kind >** will keep the DDS samples in its cache until they are acknowledged by all the Durable Subscriptions associated with the PRSTDataWriter. After the DDS samples are acknowledged by the Durable Subscriptions, they will be marked as reclaimable but they will not be purged from the PRSTDataWriter’s queue until the *DataWriter* needs these resources for new DDS samples. This may lead to inefficient resource utilization, especially when **< max\_samples >** is high or UNLIMITED.

The PRSTDataWriter behavior can be changed to purge DDS samples after they have been acknowledged by all the active/matching *DataReaders* and all the Durable Subscriptions configured for the **< persistence\_service >**. To do so, set the tag **< purge\_samples\_after\_acknowledgment >** under **< persistence\_service >** to TRUE. Notice that this setting is global to the service and applies to all the PRSTDataWriters created by each **< persistence\_group >**.

## 74.10 Synchronizing of Persistence Service Instances

By default, different *Persistence Service* instances do *not* synchronize with each other. For example, in a scenario with two *Persistence Service* instances, the first persistence service could receive a DDS sample ‘S1’ from the original *DataWriter* that is not received by the second persistence service. If the disk where the first persistence service stores its DDS samples fails, ‘S1’ will be lost.

To enable synchronization between *Persistence Servic* instances, use the tag **<synchronization>** under **<persistence\_service>**. When it comes to synchronization, there are two different kinds of information that can be synchronized independently:

- Information about Durable Subscriptions and their states (see [74.9 Configuring Durable Subscriptions in Persistence Service on page 1226](#))
- DDS data samples

**Table 74.9 Synchronization Tags**

Tags within <synchronization>	Description	Number of Tags Allowed
<synchronize_data>	<p>Enables synchronization of DDS data samples in redundant <i>Persistence Service</i> instances.</p> <p>When set to 1, DDS samples lost on the way to one service instance can be repaired by another without impacting the original publisher of that message.</p> <p>To synchronize the instances, the tag &lt;synchronize_data&gt; must be set to 1 in every instance involved in the synchronization.</p> <p>Note: This DDS sample synchronization mechanism is not equivalent to database replication. The extent to which database instances have identical contents depends on the destination ordering and other QoS settings for the <i>Persistence Service</i> instances.</p> <p>Default: 0</p>	0 or 1
<synchronize_durable_subscription>	<p>Enables synchronization of Durable Subscriptions in redundant <i>Persistence Service</i> instances.</p> <p>When set to 1, the different <i>Persistence Service</i> instances will synchronize their Durable Subscription information. This information includes the set of Durable Subscriptions as well as information about the Durable Subscription’s state, such as the DDS samples that have already been received by the Durable Subscriptions.</p> <p>Default: 0</p>	0 or 1
<durable_subscription_synchronization_period>	<p>The period (in milliseconds) at which the information about Durable Subscriptions is synchronized.</p> <p>Default: 5000 milliseconds</p>	0 or 1

## 74.11 Enabling RTI Distributed Logger in Persistence Service

*Persistence Service* provides integrated support for *RTI Distributed Logger* (see [54.6 RTI Distributed Logger on page 1103](#)).

*Distributed Logger* is included in *Connex* but it is not supported on all platforms; see the [RTI Connex Core Libraries Platform Notes](#) to see which platforms support *Distributed Logger*.

When you enable *Distributed Logger*, *Persistence Service* will publish its log messages to *Connex*. Then you can use *RTI Monitor*<sup>1</sup> to visualize the log message data. Since the data is provided in a *Connex* topic, you can also use *rtiddsspy* or even write your own visualization tool.

To enable *Distributed Logger*, modify the *Persistence Service* XML configuration file. In the <administration> section, add the <distributed\_logger> tag as shown in the example below.

```
<persistence_service name="default">
  ...
  <administration>
    ...
    <distributed_logger>
      <enabled>true</enabled>
    </distributed_logger>
    ...
  </administration>
  ...
</persistence_service>
```

There are more configuration tags that you can use to control *Distributed Logger*'s behavior. For example, you can specify a filter so that only certain types of log messages are published. For details, see [Enabling Distributed Logger in RTI Services \(54.6.2 on page 1112\)](#)

## 74.12 Enabling RTI Monitoring Library in Persistence Service

*Persistence Service* provides integrated support for *RTI Monitoring Library* (see [Chapter 59 RTI Monitoring Library on page 1126](#)).

To enable monitoring in *Persistence Service*, you must specify the property **rti.monitor.library** for the participants that you want to monitor. For example:

---

<sup>1</sup>*RTI Monitor* is a separate GUI application that can run on the same host as your application or on a different host.

```

<persistence_service name="monitoring_test">
  <participant name="monitoring_enabled_participant">
    <domain_id>54</domain_id>
    <domain_participant_qos>
      <property>
        <value>
          <element>
            <name>rti.monitor.library</name>
            <value>rtimonitoring</value>
            <propagate>>false</propagate>
          </element>
        </value>
      </property>
    </domain_participant_qos>
    <persistence_group name="persistAll">
      ...
    </persistence_group>
  </participant>
</persistence_service>

```

Since *Persistence Service* is statically linked with *RTI Monitoring Library*, you do *not* need to have it in your library search path.

For details on how to configure the monitoring process, see [Configuring Monitoring Library \(59.5 on page 1136\)](#).

## 74.13 Support for Extensible Types

*Persistence Service* includes partial support for the [OMG 'Extensible and Dynamic Topic Types for DDS' specification, version 1.3](#). This section assumes that you are familiar with Extensible Types and you have read the [RTI Connex Core Libraries Extensible Types Guide](#).

Persistence groups can publish and subscribe to topics associated with final, appendable, and mutable types.

### 74.13.1 TypeConsistencyEnforcementQosPolicy Integration

The service will automatically create different pairs (PRSTDataReader, PRSTDataWriter) for each version of a type discovered for a topic in a persistence group. In *Connex* 5.0, it is not possible to associate more than one type with a topic within a single *DomainParticipant*, therefore each version of a type requires its own *DomainParticipant*.

The [48.6 TYPE\\_CONSISTENCY\\_ENFORCEMENT QosPolicy on page 894](#) **kind** for each PRSTDataReader is set to `DISALLOW_TYPE_COERCION`. This value cannot be overwritten by the user.

For example:

```

struct A {
    int32 x;
};
struct B {

```

```
int32 x;
int32 y;
};
```

Let's assume that *Persistence Service* is configured as follows and we have two *DataWriters* on Topic "T" publishing type "A" and type "B" and sending *TypeObject* information.

```
<persistence_service name="XTypes">
  <participant name="XTypesParticipant">
    <persistence_group name="XTypesPersistenceGroup">
      <filter>T</filter>
    </persistence_group>
  </participant>
</persistence_service>
```

When *Persistence Service* discovers the first *DataWriter* with type "A", it will create a *DataReader* (PRSTDataReader) to read DDS samples from that *DataWriter*, and a *DataWriter* (PRSTDataWriter) to publish and store the received DDS samples so they can be available to late-joiners.

When *Persistence Service* discovers the second *DataWriter* with type "B", it will see that type "B" is not equal to type "A"; then it will create a new pair (PRSTDataReader, PRSTDataWriter) to receive and store DDS samples from the second *DataWriter*.

Since the PRSTDataReaders are created with the *TypeConsistencyEnforcementQosPolicy*'s **kind** set to `DISALLOW_TYPE_COERCION`, the PRSTDataReader with type "A" will not match the *DataWriter* with type "B". Likewise, the PRSTDataReader with type "B" will not match the *DataWriter* with type "A".

### 74.13.1.1 Type Version Discrimination

*Persistence Service* uses the rules described in the [RTI Connex Core Libraries Extensible Types Guide](#) to decide whether or not to create a new pair (PRSTDataReader, PRSTDataWriter) when it discovers a *DataWriter* for a topic "T".

For *DataWriters* created with previous *Connex* releases, *Persistence Service* will select the first pair (PRSTDataReader, PRSTDataWriter) with a registered type name equal to the discovered registered type name since *DataWriters* created with previous *Connex* releases (before 5.0) do not send *TypeObject* information.

## 74.13.2 DataRepresentationQosPolicy Integration

There are some restrictions on how the [47.3 DATA\\_REPRESENTATION QosPolicy on page 780](#) is configured for the PRSTDataReader and PRSTDataWriter in a persistence group:

- A PRSTDataReader cannot be configured to request two or more data representations. For example, it is not possible to request XCDR and XCDR2. Subscribing to a *Topic* in which data is published in XCDR and XCDR2 format requires creating two different persistence groups.

- The data representation requested by a PRSTDataReader has to be equal to the data representation offered by the corresponding PRSTDataWriter.

## 74.14 TCP Transport Support in Persistence Service

You can configure *Persistence Service's* Participants to use the TCP Transport. To do so, enable the TCP Transport under the proper XML Persistence Service's `<domain_participant_qos>` tag.

Make sure the string prefix passed in the property `dds.transport.load_plugins` is `"dds.transport.tcp"`. For more information about how to enable the TCP Transport, please see [53.2.7 TCP/TLS Transport Properties on page 1065](#).

Note that the *Persistence Service's* `domain_participant_qos` will be used at least by two Participants: one for sending data and another for receiving data. Consequently, at least two TCP Transport plugins will be instantiated when enabling the TCP Transport. In order to avoid port collisions, *Persistence Service* will automatically assign consecutive ports. For a base, it will use the values set for `dds.transport.tcp.server_bind_port` (only when it is non-zero) and `dds.transport.tcp.public_address` (only if it is set). Consequently, the Participants creating a TCP Transport running as a server will open a minimum of two TCP ports.

# Chapter 75 Running RTI Persistence Service

This chapter describes how to start and stop *Persistence Service*.

You can run *Persistence Service* on any node in the network. It does not have to be run on the same node as the publishing or subscribing applications for which it is saving/delivering data. If you run it on a separate node, make sure that the other applications can find it during the discovery process—that is, it must be in one of the `NDDS_DISCOVERY_PEERS` lists.

## 75.1 Starting Persistence Service

The script to run *Persistence Service*'s executable is located in `<NDDSHOME>/bin`.

To run this service executable on a *target* system (not your host development platform), you must first select the target architecture. To do so, either:

- Set the environment variable `CONNEXTDDS_ARCH` to the name of the target architecture. (Do this for each command shell you will be using.)
- Or set the variable `connextdds_architecture` in the file `rticommon_config.[sh/bat]`<sup>a</sup> to the name of the target architecture. If the `CONNEXTDDS_ARCH` environment variable is set, the architecture in this file will be ignored.

Run `rtipersistenceservice -help` to see descriptions of the command-line options, which are also described in more detail in [Table 75.1 Persistence Service Command-Line Options](#).

---

<sup>a</sup>This file is `resource/scripts/rticommon_config.sh` on Linux or macOS systems, `resource/scripts/rticommon_config.bat` on Windows systems.

Table 75.1 Persistence Service Command-Line Options

Command-line Option	Description
-appName <string>	<p>Assigns a name to the execution of <i>Persistence Service</i>.</p> <p>Remote commands will refer to the persistence service using this name.</p> <p>In addition, the name of the <i>DomainParticipants</i> created by <i>Persistence Service</i> will be based on this name as follows:  RTI Persistence Service: &lt;appName&gt;: &lt;participantName&gt;(&lt;pub sub&gt;)  Default: The name given with <b>-cfgName</b> if present, otherwise it is "RTI_Persistence_Service"</p>
-cfgFile <string>	<p>Specifies an XML configuration file for the <i>Persistence Service</i>.</p> <p>The parameter is optional since the <i>Persistence Service</i> configuration can be loaded from other locations. See <a href="#">74.1 How to Load the Persistence Service XML Configuration on page 1208</a> for further details.</p>
-cfgName <string>	<p><b>Required.</b></p> <p>Selects a <i>Persistence Service</i> configuration.</p> <p>The same configuration files can be used to configure multiple persistence services. Each <i>Persistence Service</i> instance will load its configuration from a different &lt;persistence_service&gt; tag based on the name specified with this option.</p> <p>If not specified, <i>Persistence Service</i> will print the list of available configurations and then exit.</p>
-identifyExecution	<p>Appends the host name and process ID to the service name provided with the <b>-appName</b> option. This helps ensure unique names for remote administration.</p>
-enableDatabaseLocking	<p>Prevents multiple instances of <i>Persistence Service</i> from accessing the same database. This feature only has effect when &lt;persistent_storage&gt; is used.</p> <p>Default: Database locking is disabled. By default, multiple instances of <i>Persistence Service</i> can access the same database.</p>
-domainId <ID>	<p>Sets the domain ID for the <i>DomainParticipants</i> created by <i>Persistence Service</i>.</p> <p>If not specified, the value in the &lt;participant&gt; XML tag (see <a href="#">Table 74.6 Participant Tags</a>) is used.</p>
-remoteAdministrationDomainId <ID>	<p>Enables remote administration and sets the domain ID for remote communication.</p> <p>When remote administration is enabled, <i>Persistence Service</i> will create a <i>DomainParticipant</i>, <i>Publisher</i>, <i>Subscriber</i>, <i>DataWriter</i>, and <i>DataReader</i> in the designated DDS domain.</p> <p>This option overwrites the value of the tag &lt;domain_id&gt; within &lt;administration&gt;.</p> <p>Default: Use the value &lt;domain_id&gt; under &lt;administration&gt;.</p>
-help	<p>Prints the <i>Persistence Service</i> version and list of command-line options.</p>
-licenseFile <file>	<p>Specifies the license file (path and filename). Only applicable to licensed-managed (LM) versions of <i>Persistence Service</i>.</p> <p>If not specified, <i>Persistence Service</i> looks for the license as described in the <a href="#">RTI Connex Installation Guide</a>.</p>
-restore <0 1>	<p>Indicates whether or not <i>Persistence Service</i> must restore its state from the persistent storage. 0 = do not restore; 1 = do restore.</p> <p>If this option is not specified, the corresponding XML value in the &lt;persistent_storage&gt; tag (see <a href="#">Table 74.4 Persistent Storage tags</a>) is used.</p> <p>Setting this option to 1 requires that the service configuration name (-cfgName) used to restore the <i>Persistence Service</i> state is the same as the configuration name that was used to create the state.</p>
-noAutoStart	<p>Indicates that <i>Persistence Service</i> will not be started when the process is executed.</p> <p>Use this option if you plan to start <i>Persistence Service</i> remotely, as described in <a href="#">Administering Persistence Service from a Remote Location (Chapter 76 on page 1236)</a>.</p>

Table 75.1 Persistence Service Command-Line Options

Command-line Option	Description
-infoDir <dir>	<p>The info directory of the running <i>Persistence Service</i>.</p> <p>Using this command line option, <i>Persistence Service</i> can be configured to create a file used to monitor the status of the last shutdown.</p> <p>At startup, the <i>Persistence Service</i> instance will create a file called <b>ps.pid</b> into the directory specified by <b>-infoDir</b>.</p> <p>If <i>Persistence Service</i> is shutdown gracefully, the file will be deleted before the process exists.</p> <p>If <i>Persistence Service</i> is not shutdown gracefully, the file will not be deleted.</p> <p>You can detect the shutdown state of <i>Persistence Service</i> by checking for the presence of the <b>ps.pid</b> file.</p> <p>If the file is present and <i>Persistence Service</i> is no longer running, the previous shutdown was not graceful.</p> <p>If <i>Persistence Service</i> is started and a <b>ps.pid</b> file exists, <i>Persistence Service</i> will immediately shutdown. In this case, you must remove the file before <i>Persistence Service</i> can be restarted again.</p> <p>Default: The file <b>ps.pid</b> will not be generated.</p>
-maxObjectsPerThread <int>	<p>Parameter used to configure the maximum objects per thread in the DomainParticipantFactory created by <i>Persistence Service</i>. It is usually recommended to keep the value set to the default. See <a href="#">43.3 SYSTEM_RESOURCE_LIMITS QoS Policy (DDS Extension) on page 693</a> for more details.</p> <p>Default: <i>Connex</i> default</p>
-heapSnapshotPeriod	<p>Enables heap monitoring.</p> <p><i>Persistence Service</i> will generate a heap snapshot every <i>n</i> seconds.</p> <p>Default: Heap monitoring is disabled.</p> <p>Valid range: [1, 86400]</p>
-serviceThreadStackSize <int>	<p>Service thread stack size.</p> <p>Default: <i>Connex</i> default</p>
-verbosity	<p><i>Persistence Service</i> verbosity:</p> <ul style="list-style-type: none"> <li>0 - No verbosity</li> <li>1 - Exceptions (Core Libraries and <i>Persistence Service</i>)</li> <li>2 - Warning (<i>Persistence Service</i>)</li> <li>3 - Information (<i>Persistence Service</i>)</li> <li>4 - Warning (Core Libraries and <i>Persistence Service</i>)</li> <li>5 - Tracing (<i>Persistence Service</i>)</li> <li>6 - Tracing (Core Libraries and <i>Persistence Service</i>)</li> </ul> <p>Each verbosity level, <i>n</i>, includes all the verbosity levels smaller than <i>n</i>.</p> <p>Default: 1</p>
-version	<p>Prints the <i>Persistence Service</i> version.</p>

## 75.2 Stopping Persistence Service

**To stop Persistence Service:** Press **Ctrl-C**.

*Persistence Service* will close all files and perform a clean shutdown. It can also be stopped and shutdown remotely (see [Administering Persistence Service from a Remote Location \(Chapter 76 on page 1236\)](#)).

# Chapter 76 Administering Persistence Service from a Remote Location

*Persistence Service* can be controlled remotely by sending commands through a special Topic. Any *Connex* application can be implemented to send these commands and receive the corresponding responses. A shell application that sends/receives these commands is provided with *Persistence Service*.

The script for the shell application is `$NDDSHOME/bin/rtipssh`.

Entering `rtipssh -help` will show you the command-line options:

```
RTI Persistence Service Shell v7.0.0
Usage: rtipssh [options]...
Options:
  -domainId <integer>   Domain ID for the remote configuration
  -timeout <seconds>    Max time to wait a remote response
  -cmdFile <file>       Run commands in this file
  -help                  Displays this information
```

## 76.1 Enabling Remote Administration

By default, remote administration is disabled in *Persistence Service*.

To enable remote administration you can use the `<administration>` tag (see [74.5 Configuring Remote Administration on page 1215](#)) or the `-remoteAdministrationDomainId` command-line parameter (see [Table 75.1 Persistence Service Command-Line Options](#)), which enables remote administration and sets the domain ID for remote communication.

When remote administration is enabled, *Persistence Service* will create a *DomainParticipant*, *Publisher*, *Subscriber*, *DataWriter*, and *DataReader* in the designated DDS domain. (The QoS values for these entities are described in [74.5 Configuring Remote Administration on page 1215](#).)

## 76.2 Remote Commands

This section describes the remote commands using the shell interface; [76.3 Accessing Persistence Service from a Connex Application on the next page](#) explains how to use remote administration from a *Connex* application.

Remote commands:

```
start <target_persistence_service>
stop <target_persistence_service>
shutdown <target_persistence_service>
status <target_persistence_service>
```

### Parameters:

*<target\_persistence\_service>* can be:

- The application name of a persistence service, such as “**MyPersistenceService1**”, as specified at start-up with the command-line option **-appName**
- A wildcard expression<sup>1</sup> for a persistence service name, such as “**MyPersistenceService\***”

### 76.2.1 start

```
start <target_persistence_service>
```

The **start** command starts the persistence service instance. DDS samples will not be persisted until the persistence service is started.

By default, the persistence service is started automatically when the process is executed. To start the service remotely use the command line option **-noAutoStart** (see [Table 75.1 Persistence Service Command-Line Options](#)).

### 76.2.2 stop

```
stop <target_persistence_service>
```

The **stop** command stops the persistence service instance.

An instance that has been stopped can be started again using the command **start**.

### 76.2.3 shutdown

```
shutdown <target_persistence-_service>
```

The command **shutdown** stops the persistence service instance and finalizes the process

---

<sup>1</sup>As defined by the POSIX fnmatch API (1003.2-1992 section B.6)

## 76.2.4 status

```
status <target_persistence_service>
```

The **status** command gets the status of a running persistence service instance. Possible values are STARTED and STOPPED.

## 76.3 Accessing Persistence Service from a Connex Application

You can send commands to control a Persistence Service instance from your own *Connex* application. You will need to create a *DataWriter* for a specific topic and type. Then, you can send a DDS sample that contains a command and its parameters. Optionally, you can create a *DataReader* for a specific topic to receive the results of the execution of your commands.

The topics are:

- rti/persistence\_service/administration/command\_request
- rti/persistence\_service/administration/command\_response

The types are:

- RTI::PersistenceService::Administration::CommandRequest
- RTI::PersistenceService::Administration::CommandResponse

You can find the IDL definitions for these types in:

**<NDDSHOME>/resource/idl/PersistenceServiceAdministration.idl.**

The QoS configuration of your *DataWriter* and *DataReader* must be compatible with the one used by the persistence service (see how this QoS is configured in [74.5 Configuring Remote Administration on page 1215](#)).

The following example in C shows how to send a command to shutdown a persistence service instance:

```

/*****
/**** Create the Entities needed to send command request ****
/****
participant = DDS_DomainParticipantFactory_create_participant(
    DDS_TheParticipantFactory, domainId,
    &DDS_PARTICIPANT_QOS_DEFAULT, NULL,
    DDS_STATUS_MASK_NONE);
if (participant == NULL)
{ /* Error */ }
if (publisher == NULL)
{ /* Error */ }

subscriber = DDS_DomainParticipant_create_subscriber(
    participant, &DDS_SUBSCRIBER_QOS_DEFAULT,
    NULL, DDS_STATUS_MASK_NONE);

count++;
}
if (count == maxPollPeriods) {
    printf("No response received\n");
} else {
    printf("Response received: %s\n", response->message);
}
```

# Chapter 77 Advanced Persistence Service Scenarios

This section covers several advanced scenarios for using *Persistence Service*.

## 77.1 Scenario: Load-balanced Persistence Services

Each running instance of the *Persistence Service* executes as a single process in a single computer. In high-throughput scenarios the *Persistence Service* may become a bottleneck. The main reasons are:

- If the *Persistence Service* is configured to persist its DDS samples to durable storage (a disk or a database) this will further limit the throughput of DDS samples that can be persisted to what the database and/or disk can handle. Depending on computer hardware, the disk or database this limit may be in the order of tens of thousands of DDS samples per second which is far less than what could be communicated system-wide.
- Depending on the CPU there will be limits on the throughput of DDS samples that can be received by a single process.
- The computer running the *Persistence Service* is typically connected to the network via a single network interface so the data that can be persisted will be limited to the throughput that flows through a single interface which is typically far less than the aggregated throughput that can flow on the complete network.

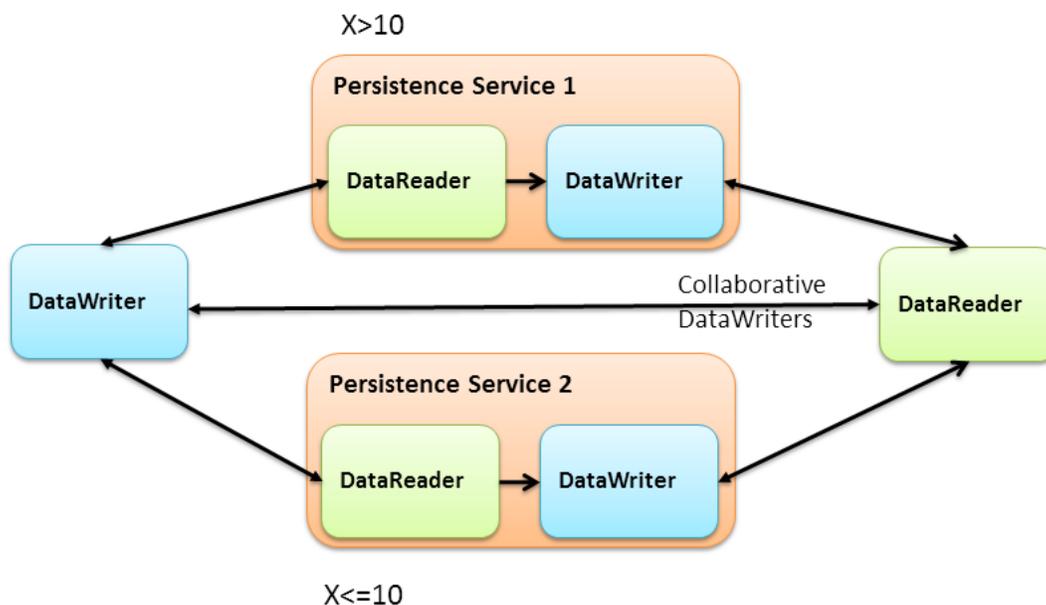

To overcome these limits multiple instances of the RTI *Persistence Service* can be run in parallel. These instances may run in multiple machines and be configured in a “load balancing” fashion such that each *Persistence Service* process is only responsible for persisting a subset of the data published on the DDS domain.

Multiple strategies for partitioning the data stored by each *Persistence Service* instance are possible:

- **Balance Persistence Services by Topic name.** This strategy configures each persistence service to persist different Topic names. This is accomplished by associating a filter expression with the declaration of the persistent groups used to configure each *Persistence Service* (see [74.8 Creating Persistence Groups on page 1220](#)). The filter expression is applied to the Topic names, so for example one *Persistence Service* could be configured with the filter “[A-Z]\*” filter in the name of the Topics that it will persist and the second with the filter “[a-z]\*”. With this configuration the first *Persistence Service* will persist data produced by DataWriters that specify durability TRANSIENT or PERSISTENT and have a Topic name that starts with a capital letter and the second *Persistence Service* will do the same for Topics that start with a lower-case letter.
- **Balance Persistence Services by data content.** In some scenarios the data published on a single Topic is too much for a single *Persistence Service* to handle. In this case the *Persistence Services* can also be configured with filter expressions based on the content of the data. This is accomplished by associating a content filter with the declaration of the persistent groups used to configure each *Persistence Service* (see [74.8 Creating Persistence Groups on page 1220](#)).

When multiple instances of *Persistence Service* are used to store data on the same Topic, it becomes possible for DDS samples from the same original *DataWriter* to be stored in separate instances of *Persistence Service*. In this situation, *Connex DataReaders* automatically merge the data from the multiple *Persistence Services* such that the relative order of the DDS samples from the original *DataWriter* is preserved. This *Connex* capability is called *Collaborative Datawriters* because multiple *DataWriters*, in this case the ones for different *Persistence Services*, collaborate to reconstruct the original stream. (See [Collaborative DataWriters \(Maintain Global, Ordered Set of Samples\) \(Chapter 37 on page 588\)](#)).

Figure 77.1: Load-Balanced Persistence Services Scenario

## 77.2 Scenario: Delegated Reliability

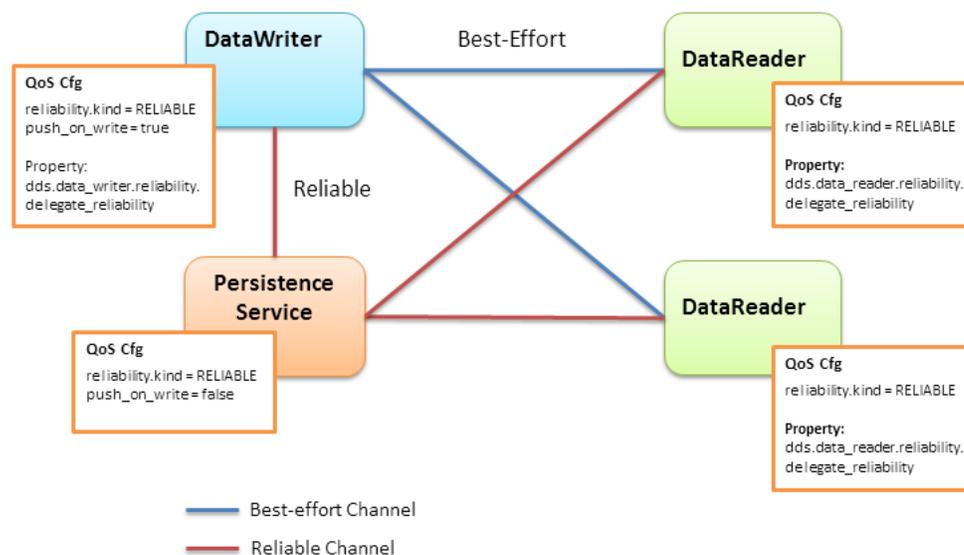

The DDS-RTPS reliability protocol requires the *DataWriter* to periodically send HeartBeat messages to the *DataReaders*, process their ACKs and NACK messages, keep track of the *DataReader* state, and send the necessary repairs. The additional load caused by the reliability protocol increases with the number of reliable *DataReaders* matched with the *DataWriter*. Even if the data is sent via multicast the number of ACKs and NACKs will increase with the number of *DataReaders*.

In situations where there many *DataReaders* are subscribing to the same Topic, the reliability and repair traffic may become too much for the *DataWriter* to handle and negatively impact its performance. To address this situation, *Connex* provides the ability to configure the *DataWriter* so that it delegates the reliability task to a separate service. This approach is known as *delegated reliability*.

To take advantage of *delegated reliability*, both the original *DataWriter* and *DataReader* must be configured to enable an external service to ensure the reliability on their behalf. This is done by setting both the `dds.data_writer.reliability.delegate_reliability` property on the *DataWriter* and the `dds.data_reader.reliability.delegate_reliability` property on the *DataReader* to 1.

With this configuration, the *DataWriter* creates a reliable channel to *Persistence Service*, yet sends data using ‘best-effort’ reliability to the *DataReaders* directly. If a DDS sample is dropped, *Persistence Service* will repair the DDS sample. *Persistence Service* is configured with `push_on_write` (in the [47.5 DATA\\_WRITER\\_PROTOCOL QoS Policy \(DDS Extension\) on page 788](#)) set to false. This way, DDS samples will only be sent from *Persistence Service* to the *DataReaders* when they are explicitly NACKed by the *DataReader*.

Figure 77.2: Delegated Reliability Scenario

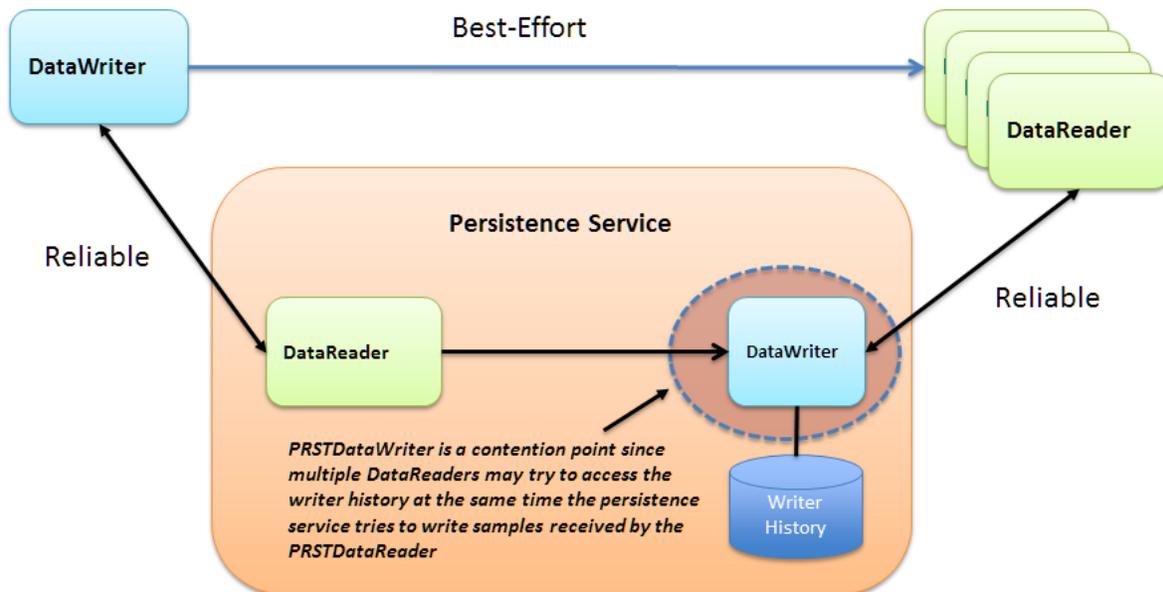

## 77.3 Scenario: Slow Consumer

Unless special measures are taken, the presence of slow consumers can impact the overall behavior of the system. If a *DataReader* is not keeping up with the DDS samples being sent by the *DataWriter*, it will apply back-pressure to the *DataWriter* to slow the rate at which the *DataWriter* can write DDS samples. With *delegated reliability* (see [77.2 Scenario: Delegated Reliability on the previous page](#)), the original *DataWriter* can offload the processing of the ACK/NACK messages generated by the *DataReaders* to a *PRSTDataWriter*. However, the original *DataWriter* still has a reliable channel with the *PRSTDataReader* that can slow it down.

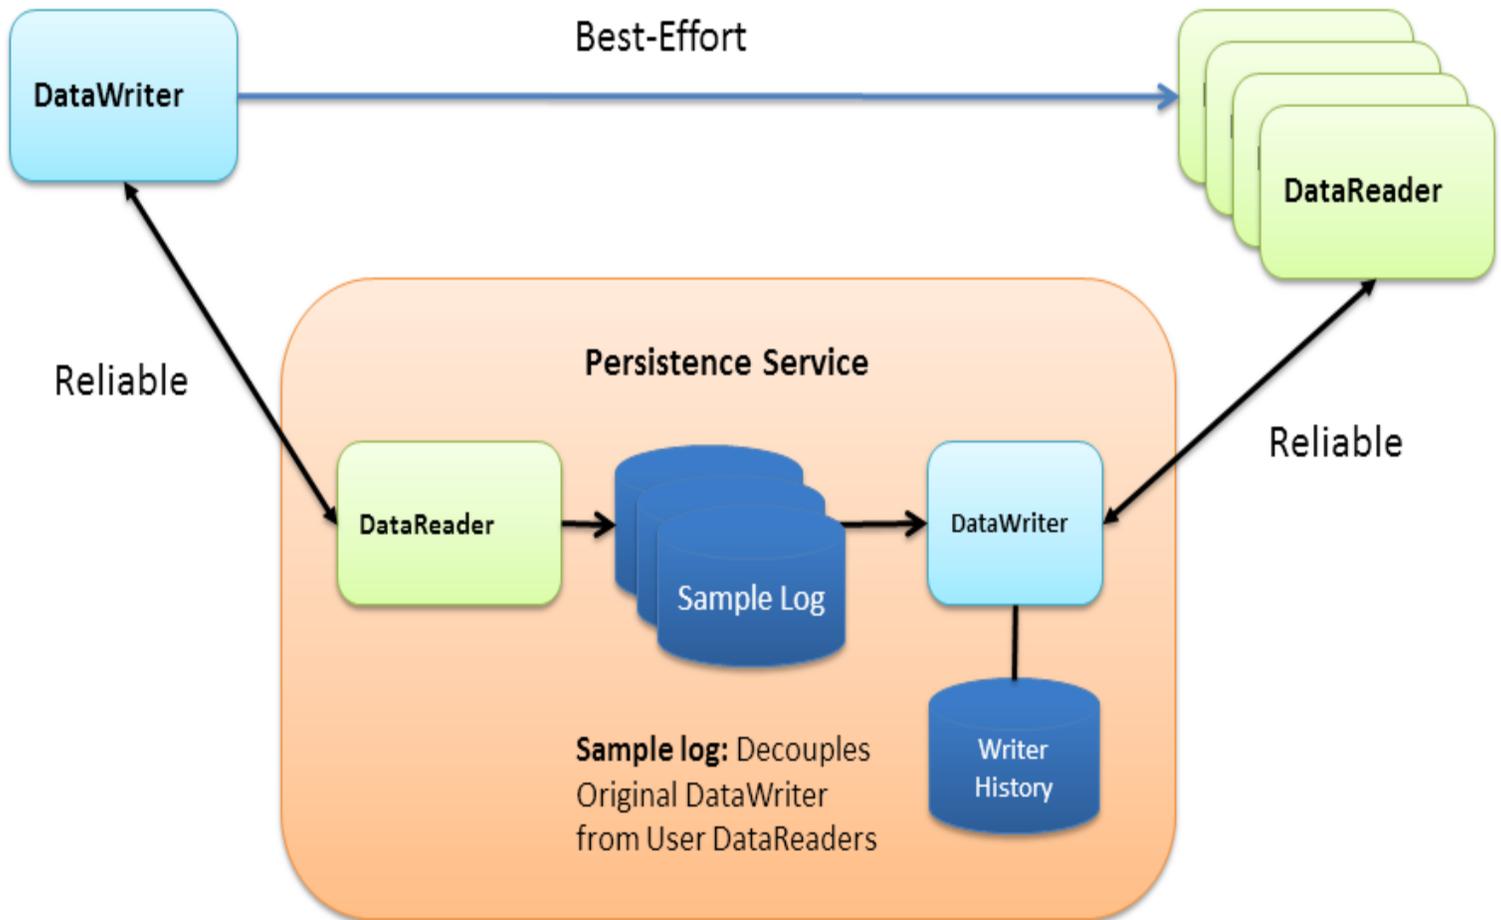

By default, *Persistence Service* uses the *Connex* receive thread to read DDS samples from the *PRStDataReaders*, write the DDS samples to the *PRSTDataWriters* history, and send ACKs to the original *DataWriter*. With this configuration, a *PRSTDataReader* does not ACK DDS samples to the original *DataWriter* until they are written into the corresponding *PRSTDataWriter*'s history. Since multiple *DataReaders* may be accessing the *PRSTDataWriter* history at the same time that the persistence service is trying to write new DDS samples, the *PRSTDataWriter* history becomes a contention point that can indirectly slow down the original *DataWriter* (see [Figure 77.3: Slow-Consumer Scenario with Delegated Reliability below](#)).

Figure 77.3: Slow-Consumer Scenario with Delegated Reliability

To remove this contention point and decouple the slow consumer from the original *DataWriter*, *Persistence Service* supports a mode where DDS samples can be buffered prior to being added to the *PRSTDataWriter*'s queue (see [Figure 77.4: Slow Consumer Scenario with Delegated Reliability and DDS Sample Log on the next page](#)).

Figure 77.4: Slow Consumer Scenario with Delegated Reliability and DDS Sample Log

If the *PRSTDataWriter* slows down due to the presence of slow consumers, the buffer will hold DDS samples such that the original *DataWriter* and the rest of the system are not impacted. This buffer is called the *Persistence Service sample log*. The persistence service creates a separate DDS sample log per *PRSTDataWriter* in the group. In addition to the DDS sample log, the persistence service creates a thread (write thread) whose main function is to read DDS samples from the log and write them to the associated *PRSTDataWriter*. There is one thread per *PRSTDataWriter*.

*Persistence Service* currently does not allow multiple DDS sample logs to share the same write thread.

*Persistence Service* can be configured to enable DDS sample logging per persistence group using the `<sample_logging>` XML tag to specify the log's configuration parameters—see [Table 77.1 Sample Logging Tags](#).

Table 77.1 Sample Logging Tags

Tags within <sample_logging>	Description	Number of Tags Allowed
<enable>	A DDS_Boolean (see <a href="#">Table 74.1 Supported Tag Values</a> ) that indicates whether or not DDS sample logging is enabled in the container persistence group. Default: 0	0 or 1
<log_file_size>	Specifies the maximum size of a DDS sample log file in Mbytes. When a log file becomes full, Persistence Service creates a new log file. Default: 60 MB	0 or 1
<log_flush_period>	The period (in milliseconds) at which Persistence Service removes DDS sample log files whose full content have been written into the PRSTDataWriter by the DDS sample log write thread. Default: 10000 milliseconds	0 or 1
<log_read_batch>	Determines how many DDS samples should be read and processed at once by the DDS sample log write thread. Default: 100 DDS samples	0 or 1
<log_bookmark_period>	DDS samples in the DDS sample log are identified by two attributes: <ul style="list-style-type: none"> <li>The file ID</li> <li>The row ID (position within the file)</li> </ul> The read bookmark indicates the most recently processed DDS sample. This tag indicates how often (in milliseconds) the read bookmark is persisted into disk. Default: 1000 milliseconds	0 or 1

Enabling DDS sample logging in a persistence group is expensive. For every PRSTDataWriter, *Persistence Service* will create a write thread and an event thread that will be in charge of flushing the log files and storing the read bookmark. Therefore, DDS sample logging should be enabled only for the persistence groups where it is needed based on the potential presence of slow consumers and/or the expected data rate in the persistence group. Small data rates will likely not require a DDS sample log.
